| TM-SDU  | varies                          | C    |                     |   |
| NOTE 1: The address length of the other address types is 24.  |                                 |      |                     |   |
| NOTE 2: For values of length indication up to 010010 <sub>2</sub> , the unit of the length indication is Y <sub>2</sub> octets whereas, for higher values, the incremental unit of the length indication is Z <sub>2</sub> octets. The values of Y <sub>2</sub> and Z <sub>2</sub> depend on the bandwidth, modulation and coding rate with which the PDU is sent; the values of Y <sub>2</sub> and Z <sub>2</sub> are given in clause 21.6 for each combination. |                                 |      |                     |   |
| NOTE 3: The length of MAC PDU indicated by length indication 111101 <sub>2</sub> is set to correspond to the normal size of an advanced link data segment on a QAM channel.   |                                 |      |                     |   |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the uplink SCH/F, SCH-P8/F, SCH-Q/U or STCH.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block or less than the size of the TM-SDU indicated by the length indication field. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The encrypted flag shall indicate whether or not the TM-SDU contents are encrypted. The MAC header shall not be encrypted except that the address is encrypted when appropriate if the encrypted flag is set to 1 (for details of the address encryption method and when it is used, see ETSI EN 300 392-7 [8]). In the case of fragmentation, the setting of the encrypted flag in the MAC-DATA PDU applies to all fragments of the TM-SDU.

The address type field shall indicate the type of address contained in the address field. The length of the address field shall be 10 bits for an event label or 24 bits for SSI, USSI or SMI.

The length indication or capacity request field shall indicate whether the PDU header contains a length indication field or a capacity request field. If length indication is indicated, then the next field shall be length indication. Length indication shall refer to the length of the MAC PDU (which comprises the MAC PDU header and the TM-SDU) and shall be used if association is required or if the MS has no further signalling to send. If capacity request is indicated, the next field shall be fragmentation flag followed by reservation requirement and the reserved bit. Capacity request shall be used on SCH/F, SCH-P8/F or SCH-Q/U when the MS has further signalling to send, which may or may not be subsequent fragments of a fragmented SDU (as indicated by the fragmentation flag). The PDU may only contain either the length indication field or the capacity request field (comprising fragmentation flag, reservation requirement and the reserved bit).

The units used for the length indication depend on the bandwidth, modulation and coding rate with which the PDU is sent; see clause 21.6. The defined values of the length indication cover up to the size of the MAC block or the maximum size of a MAC-DATA PDU (2 669 bits), whichever is the lesser.

The header length of a MAC-DATA PDU depends on the type of address in use. It shall be 37 bits when an SSI, USSI or SMI is used and 23 bits when an event label is used. The maximum TM-SDU length is shown in table 21.47 for each of the header lengths and logical channels.

The length indication field may be used to indicate a null PDU. If a null PDU is indicated, there shall be no further information in the PDU after the length indication field. The length of the null PDU, therefore, shall be 23 bits if an event label is used as an address or 37 bits if an SSI, USSI or SMI is used as an address. After a null PDU, there shall be no further PDUs in the MAC block and the remaining capacity shall contain fill bits.

NOTE: The null PDU information elements before the length indication field are used as for any other MAC PDU e.g. encryption state is the same as for the other MAC PDUs.

This MAC-DATA PDU shall also be used for C-plane signalling using the STCH on the uplink. By default, the STCH occupies only the first half slot. The second half slot may also be stolen, either for the last fragment of a fragmented SDU or for subsequent PDUs which the MAC may have ready to send or for U-plane signalling. A length indication of  $11111_2$  shall be used to indicate that the second half slot is stolen for the last fragment of a fragmented SDU. A length indication of  $111110_2$  shall be used to indicate that the second half slot is stolen for subsequent C-plane signalling or U-plane signalling. The last fragment shall use the MAC-END PDU, while subsequent C-plane PDUs shall use the MAC-DATA PDU and U-plane signalling shall use the MAC-U-SIGNAL PDU. It shall only be possible to fragment SDUs over the two halves of a full slot on the STCH.

Table 21.47: Maximum length of TM-SDU in MAC-DATA PDU

| Logical channel | Maximum TM-SDU length [bits] |                        |
|-----------------|------------------------------|------------------------|
|                 | Using event label            | Using SSI, USSI or SMI |
| SCH/F           | 245                          | 231                    |
| STCH            | 101                          | 87                     |
| SCH-P8/F        | 389                          | 375                    |

| SCH-Q/U25-64M   | 758                          | 744                    |
| SCH-Q/U25-64U   | 1 161                        | 1 147                  |
| SCH-Q/U50-4H    | 366                          | 352                    |
| SCH-Q/U50-16H   | 774                          | 760                    |
| SCH-Q/U50-16U   | 1 593                        | 1 579                  |
| SCH-Q/U50-64H   | 1 182                        | 1 168                  |
| SCH-Q/U50-64M   | 1 590                        | 1 576                  |
| SCH-Q/U50-64U   | 2 409                        | 2 395                  |
| SCH-Q/U100-4H   | 782                          | 768                    |
| SCH-Q/U100-16H  | 1 606                        | 1 592                  |
| SCH-Q/U100-16U  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U100-64H  | 2 430                        | 2 416                  |
| SCH-Q/U100-64M  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U100-64U  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U150-4H   | 1 198                        | 1 184                  |
| SCH-Q/U150-16H  | 2 438                        | 2 424                  |
| SCH-Q/U150-16U  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U150-64H  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U150-64M  | 2 632 (see note)             | 2 632 (see note)       |
| SCH-Q/U150-64U  | 2 632 (see note)             | 2 632 (see note)       |

NOTE: The maximum length of TM-SDU in this MAC block is constrained by the maximum permitted size of TM-SDU (N.202) rather than by the size of the MAC block.

#### 21.4.2.4 MAC-FRAG (uplink)

This PDU shall be used to send continuation fragments of fragmented C-plane signalling data on the uplink using a full slot (SCH/F, SCH-P8/F or SCH-Q/U). Its contents shall be as shown in table 21.48.

Table 21.48: MAC-FRAG (uplink) PDU contents

| Information element | Length | Type | Value           | Remark               |
|---------------------|--------|------|-----------------|----------------------|
| MAC PDU type        | 2      | M    | 01 <sub>2</sub> | MAC-FRAG or MAC-END  |
| MAC PDU subtype     | 1      | M    | 0               | MAC-FRAG             |
| Fill bit indication | 1      | M    | 0               | No fill bits present |
|                     |        |      | 1               | Fill bit(s) present  |
| TM-SDU              | varies | M    |                 |                      |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the uplink using a full slot. A PDU subtype bit distinguishes between MAC-FRAG and MAC-END which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits which shall be added whenever the size of the TM-SDU fragment is less than the available capacity of a full slot. Fill bits may be required for this PDU because the MAC-END header length is greater than the header length of this PDU. This means that it is possible that the last fragment of an SDU may be too large to fit into a MAC-END PDU but too small to fill the maximum TM-SDU space available in the MAC-FRAG PDU. In this case, fill bits are required in the MAC-FRAG PDU and MAC-END shall be sent with a zero-length TM-SDU.

The header length of a MAC-FRAG shall be equal to 4 bits. The maximum TM-SDU length is shown in table 21.49.

**Table 21.49: Maximum length of TM-SDU in uplink MAC-FRAG PDU**

| Logical channel | Maximum TM-SDU length [bits]  |
|-----------------|---|
| SCH/F           | 264   |
| SCH-P8/F        | 408   |
| SCH-Q/U25-4H    | 177   |
| SCH-Q/U25-16H   | 377   |
| SCH-Q/U25-16U   | 780   |
| SCH-Q/U25-64H   | 577   |
| SCH-Q/U25-64M   | 777   |
| SCH-Q/U25-64U   | 1 180   |
| SCH-Q/U50-4H    | 385   |
| SCH-Q/U50-16H   | 793   |
| SCH-Q/U50-16U   | 1 612   |
| SCH-Q/U50-64H   | 1 201   |
| SCH-Q/U50-64M   | 1 609   |
| SCH-Q/U50-64U   | 2 428   |
| SCH-Q/U100-4H   | 801   |
| SCH-Q/U100-16H  | 1 625   |
| SCH-Q/U100-16U  | Not applicable (see note)   |
| SCH-Q/U100-64H  | 2 449   |
| SCH-Q/U100-64M  | Not applicable (see note)   |
| SCH-Q/U100-64U  | Not applicable (see note)   |
| SCH-Q/U150-4H   | 1 217   |
| SCH-Q/U150-16H  | 2 457   |
| SCH-Q/U150-16U  | Not applicable (see note)   |
| SCH-Q/U150-64H  | Not applicable (see note)   |
| SCH-Q/U150-64M  | Not applicable (see note)   |
| SCH-Q/U150-64U  | Not applicable (see note)   |
| NOTE:           | For these logical channels, the MAC block is large enough to contain the maximum permitted size of TM-SDU so the MS has no need to use MAC-FRAG. (It completes the TM-SDU using MAC-END instead.) |

### 21.4.2.5 MAC-END (uplink)

This PDU shall be used to send the last fragment of fragmented C-plane signalling data on the uplink using a full slot (SCH/F, SCH-P8/F or SCH-Q/U). It shall also be used to send the last fragment of fragmented C-plane signalling in the second half of a stolen full slot on the uplink. Its contents shall be as shown in table 21.50.

**Table 21.50: MAC-END (uplink) PDU contents**

| Information element   | Length | Type | Value               | Remark  |
|---|--------|------|---------------------|---|
| MAC PDU type  | 2      | M    | 01 <sub>2</sub>     | MAC-FRAG or MAC-END   |
| MAC PDU subtype   | 1      | M    | 1                   | MAC-END   |
| Fill bit indication   | 1      | M    | 0                   | No fill bits present  |
|   |        |      | 1                   | Fill bit(s) present   |
| Length indication / reservation requirement   | 6      | M    | 000000 <sub>2</sub> | Reserved  |
|   |        |      | 000001 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets (see note)                    |
|   |        |      | etc.                | etc.  |
|   |        |      | 000110 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets                               |
|   |        |      | 000111 <sub>2</sub> | Length of MAC PDU = (6 × Y <sub>2</sub> + (value - 6) × Z <sub>2</sub> ) octets |
|   |        |      | etc.                | etc.  |
|   |        |      | 101110 <sub>2</sub> | Length of MAC PDU = (6 × Y <sub>2</sub> + (value - 6) × Z <sub>2</sub> ) octets |
|   |        |      | 101111 <sub>2</sub> | Reserved  |
|   |        |      | 11XXXX <sub>2</sub> | See reservation requirement information element definition                      |
| TM-SDU  | varies | C    |                     |   |
| NOTE: For values of length indication up to 000110 <sub>2</sub> , the unit of the length indication is Y <sub>2</sub> octets whereas, for higher values, the incremental unit of the length indication is Z <sub>2</sub> octets. The values of Y <sub>2</sub> and Z <sub>2</sub> depend on the bandwidth, modulation and coding rate with which the PDU is sent; the values of Y <sub>2</sub> and Z <sub>2</sub> are given in clause 21.6 for each combination. |        |      |                     |   |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the uplink SCH/F, SCH-P8/F, SCH-Q/U or STCH. A PDU subtype bit distinguishes between MAC-FRAG and MAC-END which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the PDU is less than the available capacity of the MAC block or less than the size of the PDU indicated by the length indication field. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The next 6-bit field shall indicate length indication or a reservation requirement. A value from 000001<sub>2</sub> to 101110<sub>2</sub> shall indicate the length of the PDU. A value beginning with 11<sub>2</sub> shall indicate a reservation requirement which shall be used on SCH/F, SCH-P8/F or SCH-Q/U when the MS has further C-plane signalling to send. The reservation requirement information is contained in the 4 least significant bits of these values, the meaning of which is given in the reservation requirement element definition.

The units used for the length indication depend on the bandwidth, modulation and coding rate with which the PDU is sent; see clause 21.6. The defined values of the length indication cover up to the size of the MAC block or the maximum size of a MAC-END PDU (2 641 bits), whichever is the lesser.

The header length of a MAC-END PDU shall be equal to 10 bits. The maximum TM-SDU length is shown in table 21.51. The length indicated in the MAC PDU header shall refer to the MAC PDU which comprises the MAC PDU header and the TM-SDU.

**Table 21.51: Maximum length of TM-SDU in uplink MAC-END PDU**

| Logical channel | Maximum TM-SDU length [bits]  |
|-----------------|---|
| SCH/F           | 258   |
| STCH            | 114   |
| SCH-P8/F        | 402   |
| SCH-Q/U25-4H    | 171   |
| SCH-Q/U25-16H   | 371   |
| SCH-Q/U25-16U   | 774   |
| SCH-Q/U25-64H   | 571   |
| SCH-Q/U25-64M   | 771   |
| SCH-Q/U25-64U   | 1 174   |
| SCH-Q/U50-4H    | 379   |
| SCH-Q/U50-16H   | 787   |
| SCH-Q/U50-16U   | 1 606   |
| SCH-Q/U50-64H   | 1 195   |
| SCH-Q/U50-64M   | 1 603   |
| SCH-Q/U50-64U   | 2 422   |
| SCH-Q/U100-4H   | 795   |
| SCH-Q/U100-16H  | 1 619   |
| SCH-Q/U100-16U  | 2 631 (see note)  |
| SCH-Q/U100-64H  | 2 443   |
| SCH-Q/U100-64M  | 2 631 (see note)  |
| SCH-Q/U100-64U  | 2 631 (see note)  |
| SCH-Q/U150-4H   | 1 211   |
| SCH-Q/U150-16H  | 2 451   |
| SCH-Q/U150-16U  | 2 631 (see note)  |
| SCH-Q/U150-64H  | 2 631 (see note)  |
| SCH-Q/U150-64M  | 2 631 (see note)  |
| SCH-Q/U150-64U  | 2 631 (see note)  |
| NOTE:           | The maximum length of TM-SDU in this MAC block is constrained by the maximum permitted size of TM-SDU (N.202) rather than by the size of the MAC block. |

#### 21.4.2.6 MAC-U-BLCK

This PDU may optionally be used to send C-plane signalling data on the uplink in a full slot (SCH/F, SCH-P8/F or SCH-Q/U) in cases when an event label can be used and a pre-defined length is appropriate e.g. when sending an advanced link data segment. It cannot be used if SSI or SMI addressing or fragmentation is needed, or to indicate a null PDU; when any of these functions are needed, the MS should use the MAC-DATA PDU.

The MAC-U-BLCK PDU has a slightly smaller MAC header than the MAC-DATA PDU so can carry slightly more data. If the MS has a valid event label, it may choose to use the MAC-U-BLCK PDU instead of MAC-DATA e.g. when sending an advanced link data segment.

NOTE 1: The MAC-U-BLCK PDU should not be used when the pre-defined length is not appropriate. For example, when the MS is sending a basic link message or a short advanced link message or the last segment of an advanced link message, use of the MAC-DATA PDU may be more efficient.

The MAC-U-BLCK PDU uses the same MAC PDU type as the MAC-U-SIGNAL PDU, which is sent using the stealing channel (STCH). Therefore the MAC-U-BLCK PDU shall not be sent on STCH.

The contents of the MAC-U-BLCK PDU shall be as shown in table 21.52.

Table 21.52: MAC-U-BLCK PDU contents

| Information element           | Length | Type | Value           | Remark   |
|-------------------------------|--------|------|-----------------|--|
| MAC PDU type                  | 2      | M    | 11 <sub>2</sub> | Supplementary MAC PDU                                      |
| Supplementary MAC PDU subtype | 1      | M    | 0               | MAC-U-BLCK   |
| Fill bit indication           | 1      | M    | 0               | No fill bit present  |
|                               |        |      | 1               | Fill bit(s) present  |
| Encrypted flag                | 1      | M    | 0               | Not encrypted  |
|                               |        |      | 1               | Encrypted  |
| Address                       | 10     | M    |                 | Event label  |
| Reservation requirement       | 4      | M    |                 | See reservation requirement information element definition |
| TM-SDU                        | varies | C    |                 |  |

The length of the MAC-U-BLCK PDU is defined implicitly, as shown in table 21.53. The implicit length shall refer to the length of the MAC PDU, which comprises the MAC PDU header and the TM-SDU. For a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK slot, the implicit length matches the size of the MAC block. On a QAM channel, the implicit length of the MAC-U-BLCK PDU is set to correspond to the normal size of an advanced link data segment i.e.:

- in the case of a 25 kHz or 50 kHz channel, the implicit length corresponds to the size of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth;
- in the case of a 100 kHz or 150 kHz channel, the implicit length corresponds to half the size of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth.

Table 21.53: Implicit length of MAC-U-BLCK PDU

| Logical channel | Implicit length of MAC-U-BLCK PDU |
|-----------------|-----------------------------------|
| SCH/F           | 268 bits                          |
| SCH-P8/F        | 412 bits                          |
| SCH-Q/U25       | 181 bits                          |
| SCH-Q/U50       | 389 bits                          |
| SCH-Q/U100      | 402 bits                          |
| SCH-Q/U150      | 610 bits                          |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the uplink SCH/F, SCH-P8/F or SCH-Q/U. The supplementary MAC PDU subtype bit distinguishes between supplementary PDUs which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block or less than the size of the TM-SDU indicated by the implicit length of the MAC-U-BLCK PDU. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The encrypted flag shall indicate whether or not the TM-SDU contents are encrypted. The MAC header shall not be encrypted.

The address field shall contain an event label.

NOTE 2: As defined in ETSI EN 300 392-7 [8], the event label is not encrypted.

The reservation requirement field shall indicate the MS's current requirement for reserved slots. This field is mandatory in the MAC-U-BLCK PDU. (A specific value is defined in the reservation requirement when sent in MAC-U-BLCK for use when the MS has no further signalling to send.)

The header length of a MAC-U-BLCK PDU shall be equal to 19 bits. The maximum TM-SDU length is shown in table 21.54.

**Table 21.54: Maximum length of TM-SDU in MAC-U-BLCK PDU**

| Logical channel | Maximum TM-SDU length [bits] |
|-----------------|------------------------------|
| SCH/F           | 249                          |
| SCH-P8/F        | 393                          |
| SCH-Q/U25       | 162                          |
| SCH-Q/U50       | 370                          |
| SCH-Q/U100      | 383                          |
| SCH-Q/U150      | 591                          |

## 21.4.3 TMA-SAP: MAC PDU structure for the downlink

### 21.4.3.0 General

The following clauses describe the MAC PDUs which may be sent on the downlink and which contain C-plane signalling information for the TMA-SAP in the MS.

#### 21.4.3.1 MAC-RESOURCE

This PDU may be used to send C-plane signalling data on the downlink in a full slot (SCH/F, SCH-P8/F or SCH-Q/D), in the first or second half slot of a full slot (SCH/HD or SCH-P8/HD) or in SCH-Q/B in the QAM frequency correction burst on the downlink. It may also be used to send C-plane signalling data in the first half of a downlink slot using the Stealing Channel (STCH). If the second half of a downlink slot is also stolen, the MAC-RESOURCE PDU may be used to send another PDU in the second half slot.

This PDU may be sent without a TM-SDU in order to allocate uplink capacity, send a channel allocation or control mobile transmit power.

The contents of the MAC-RESOURCE PDU shall be as shown in table 21.55.

**Table 21.55: MAC-RESOURCE PDU contents**

| Information element | Length | Type | Value           | Remark                                      |
|---------------------|--------|------|-----------------|---|
| MAC PDU type        | 2      | M    | 00 <sub>2</sub> | MAC-RESOURCE                                |
| Fill bit indication | 1      | M    | 0               | No fill bits present                        |
|                     |        |      | 1               | Fill bit(s) present                         |
| Position of grant   | 1      | M    | 0               | Slot grant (if any) is on current channel   |
|                     |        |      | 1               | Slot grant (if any) is on allocated channel |
| Encryption mode     | 2      | M    | 00 <sub>2</sub> | Not encrypted                               |
|                     |        |      | 01 <sub>2</sub> | See ETSI EN 300 392-7 [8]                   |
|                     |        |      | 10 <sub>2</sub> | See ETSI EN 300 392-7 [8]                   |
|                     |        |      | 11 <sub>2</sub> | See ETSI EN 300 392-7 [8]                   |
| Random access flag  | 1      | M    | 0               | Undefined                                   |
|                     |        |      | 1               | Random Access Acknowledged                  |

| Information element   | Length                  | Type | Value               | Remark  |
|---|-------------------------|------|---------------------|---|
| Length indication   | 6                       | M    | 000000 <sub>2</sub> | Reserved  |
|   |                         |      | 000001 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets (see note 1)  |
|   |                         |      | etc.                | etc.  |
|   |                         |      | 010010 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets   |
|   |                         |      | 010011 <sub>2</sub> | Length of MAC PDU = (18 × Y <sub>2</sub> + (value - 18) × Z <sub>2</sub> ) octets   |
|   |                         |      | etc.                | etc.  |
|   |                         |      | 111010 <sub>2</sub> | Length of MAC PDU = (18 × Y <sub>2</sub> + (value - 18) × Z <sub>2</sub> ) octets   |

|   |                         |      |                     |   |
| Immediate napping permission flag (see note 3)  | 1                       | C    | 0                   | Immediate napping permission not given  |
|   |                         |      | 1                   | Immediate napping permission given  |
| Power control flag  | 1                       | M    | 0                   | No power control information element in PDU   |
|   |                         |      | 1                   | Power control information element in PDU  |
| Power control element   | 4                       | C    |                     | See power control information element definition  |
| Slot granting flag  | 1                       | M    | 0                   | No slot granting information elements in PDU  |
|   |                         |      | 1                   | Slot granting information element in PDU  |
| Multiple slot granting flag (see note 4)  | 1                       | C    | 0                   | Basic slot granting information element in PDU  |
|   |                         |      | 1                   | Multiple slot granting information element in PDU   |
| Basic slot granting element (see note 5)  | 8                       | C    |                     | See basic slot granting information element definition  |
| Multiple slot granting element (see note 6)   | variable                | C    |                     | See multiple slot granting information element definition   |
| Channel allocation flag   | 1                       | M    | 0                   | No channel allocation information element in PDU  |
|   |                         |      | 1                   | Channel allocation information element in PDU   |
| Channel allocation element  | variable                | C    |                     | See channel allocation information element definition   |
| TM-SDU  | variable                | C    |                     |   |
| NOTE 1: For values of length indication up to 010010 <sub>2</sub> , the unit of the length indication is Y <sub>2</sub> octets whereas, for higher values, the incremental unit of the length indication is Z <sub>2</sub> octets. The values of Y <sub>2</sub> and Z <sub>2</sub> depend on the bandwidth, modulation and coding rate with which the PDU is sent; the values of Y <sub>2</sub> and Z <sub>2</sub> are given in clause 21.6 for each combination. |                         |      |                     |   |
| NOTE 2: The length of MAC PDU indicated by length indication 111101 <sub>2</sub> is set to correspond to the normal size of an advanced link data segment on a QAM channel.   |                         |      |                     |   |
| NOTE 3: The immediate napping permission flag shall be present when the PDU is sent using π/8-D8PSK or QAM modulation. It shall not be present when the PDU is sent using π/4-DQPSK modulation.   |                         |      |                     |   |
| NOTE 4: The multiple slot granting flag shall be present when the slot granting flag is set to 1 and the PDU is sent using QAM modulation. It shall not be present when the slot granting flag is set to 0 or the PDU is sent using π/4-DQPSK or π/8-D8PSK modulation.  |                         |      |                     |   |
| NOTE 5: The basic slot granting element shall be present when the slot granting flag is set to 1 and either the PDU is sent using π/4-DQPSK or π/8-D8PSK modulation, or the PDU is sent using QAM modulation and the multiple slot granting flag is set to 0.   |                         |      |                     |   |
| NOTE 6: The multiple slot granting element shall be present when the slot granting flag is set to 1 and the PDU is sent using QAM modulation and the multiple slot granting flag is set to 1.   |                         |      |                     |   |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent in the downlink MAC block.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block or less than the size of the TM-SDU indicated by the length indication field. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The position of grant element indicates the channel on which the optional slot grant is valid. If there is no slot granting in this PDU, the MAC shall ignore the content of this bit.

The encryption mode field shall indicate whether or not the TM-SDU contents are encrypted and, if so, the encryption algorithm used. The MAC header shall not be encrypted except that, if the encryption mode field is not set to 00<sub>2</sub>:

- the channel allocation element (when present) shall be encrypted; and
- the address is encrypted when appropriate (for details of the address encryption method and when it is used, see ETSI EN 300 392-7 [8]).

NOTE 1: In the case of an event label assignment or usage marker assignment, the address element comprises two parts (SSI or SMI and event label or usage marker). The rules defined in ETSI EN 300 392-7 [8] for when address encryption is used apply independently to each part of the address.

In the case of fragmentation, the setting of the encryption mode field in the MAC-RESOURCE PDU shall apply to all fragments of the TM-SDU.

The random access flag shall be used for the BS to acknowledge a successful random access so as to prevent the MS sending further random access requests.

The length indication field shall indicate the length of the MAC PDU which comprises the MAC PDU header and the TM-SDU. If the length indication field has value of 11111<sub>2</sub>, then this shall indicate the beginning of a fragmented signalling message.

The units used for the length indication depend on the bandwidth, modulation and coding rate with which the PDU is sent; see clause 21.6. The defined values of the length indication cover up to the size of the MAC block or a MAC-RESOURCE PDU of up to 2 848 bits, whichever is the lesser.

NOTE 2: A 2848-bit MAC-RESOURCE PDU can carry the maximum size of TM-SDU (2 632 bits) with a 216-bit MAC PDU header. A 216-bit MAC PDU header allows for most combinations of the optional elements. (The MAC PDU header is not restricted to 216 bits, provided that the TM-SDU length plus the MAC PDU header length does not exceed the maximum size of MAC-RESOURCE PDU.)

NOTE 3: In exceptional circumstances, if the 2848-bit limit would be exceeded due to the BS wishing to send a very long TM-SDU (maximum size or close to the maximum size) with a very long MAC header (more than 216 bits), the BS could, for example, choose to use a basic slot granting element instead of a multiple slot granting element (or use fewer slot granting sets).

The address type field shall indicate the type of address(es) contained in the address field. The length of the address field shall be 10 bits, 24 bits, 30 bits or 34 bits depending on the type of address information contained in it.

The immediate napping permission flag shall be present when the PDU is sent using  $\pi/8$ -D8PSK or QAM modulation. This element indicates whether, after receiving this PDU, the MS may regard this address as eligible for napping.

The power control flag shall indicate whether the optional power control element is present in this PDU.

The slot granting flag shall indicate whether one of the optional slot granting elements is present in this PDU. If the slot granting flag is set to 1 then:

- if the PDU is sent using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation, the multiple slot granting flag shall not be present and the basic slot granting element shall be present; or
- if the PDU is sent using QAM modulation, the multiple slot granting flag shall be present; then:
  - if the multiple slot granting flag is set to 0, the basic slot granting element shall be present; or
  - if the multiple slot granting flag is set to 1, the multiple slot granting element shall be present.

The channel allocation flag shall indicate whether the optional channel allocation element is present in this PDU.

The header length of a MAC-RESOURCE PDU depends on the type of address information and on which of the optional fields are present. When an event label is used and there are no optional fields present, the minimum header length shall be 29 bits if the PDU is sent using  $\pi/4$ -DQPSK modulation or 30 bits if the PDU is sent using  $\pi/8$ -D8PSK or QAM modulation. The maximum TM-SDU length when an event label is used and there are no optional fields present is shown in table 21.56.

The address type field may be used to indicate a null PDU (address type = 000<sub>2</sub>). If a null PDU is indicated, there shall be no further information in the PDU after the address type field. The length of the null PDU, therefore, shall be 16 bits. On STCH, the length indication field may indicate whether the second half slot is stolen. Otherwise the length indication shall be set according to the length of the null PDU (i.e. set to 000010<sub>2</sub> if  $Y_2$  is 1 or to 000001<sub>2</sub> if  $Y_2$  is 2). All other fields in a null PDU (i.e. Fill bit indication, Position of grant, Encryption mode, and Random access flag) may be set to any value by the BS and shall be ignored by the MS in the present document. If the null PDU is present in a MAC block, then there shall be no subsequent PDUs in that block and any spare capacity shall be filled with fill bits.

This PDU shall also be used for C-plane signalling using the STCH on the downlink. By default, the STCH occupies only the first half slot. The second half slot may also be stolen, either for the last fragment of a fragmented SDU or for subsequent PDUs which the MAC may have ready to send or for U-plane signalling. A length indication of 11111<sub>2</sub> shall be used to indicate that the second half slot is stolen for the last fragment of a fragmented SDU. A length indication of 111110<sub>2</sub> shall be used to indicate that the second half slot is stolen for subsequent C-plane signalling or U-plane signalling. The last fragment shall use the MAC-END PDU, while subsequent C-plane PDUs shall use the MAC-RESOURCE PDU and U-plane signalling shall use the MAC-U-SIGNAL PDU. It shall only be possible to fragment SDUs over the two halves of a full slot on the STCH.

**Table 21.56: Maximum length of TM-SDU in downlink MAC-RESOURCE PDU**

| Logical channel | Maximum TM-SDU length [bits] with event label and no optional fields  |
|-----------------|---|
| SCH/F           | 239   |
| SCH/HD          | 95  |
| STCH            | 95  |
| SCH-P8/F        | 382   |
| SCH-P8/HD       | 166   |
| SCH-Q/D25-4H    | 155   |
| SCH-Q/D25-16H   | 359   |
| SCH-Q/D25-16U   | 770   |
| SCH-Q/D25-64H   | 563   |
| SCH-Q/D25-64M   | 767   |
| SCH-Q/D25-64U   | 1 178   |
| SCH-Q/D50-4H    | 391   |
| SCH-Q/B50       | 187   |
| SCH-Q/D50-16H   | 831   |
| SCH-Q/D50-16U   | 1 714   |
| SCH-Q/D50-64H   | 1 271   |
| SCH-Q/D50-64M   | 1 711   |
| SCH-Q/D50-64U   | 2 594   |
| SCH-Q/D100-4H   | 863   |
| SCH-Q/B100      | 659   |
| SCH-Q/D100-16H  | 1 775   |
| SCH-Q/D100-16U  | 2 632 (see note)  |
| SCH-Q/D100-64H  | 2 632 (see note)  |
| SCH-Q/D100-64M  | 2 632 (see note)  |
| SCH-Q/D100-64U  | 2 632 (see note)  |
| SCH-Q/D150-4H   | 1 335   |
| SCH-Q/B150      | 1 131   |
| SCH-Q/D150-16H  | 2 632 (see note)  |
| SCH-Q/D150-16U  | 2 632 (see note)  |
| SCH-Q/D150-64H  | 2 632 (see note)  |
| SCH-Q/D150-64M  | 2 632 (see note)  |
| SCH-Q/D150-64U  | 2 632 (see note)  |
| NOTE:           | The maximum length of TM-SDU in this MAC block is constrained by the maximum permitted size of TM-SDU (N.202) rather than by the size of the MAC block. |

### 21.4.3.2 MAC-FRAG (downlink)

This PDU shall be used to send continuation fragments of fragmented C-plane signalling data on the downlink using half slot (SCH/HD or SCH-P8/HD) or full slot (SCH/F, SCH-P8/F or SCH-Q/D) or SCH-Q/B signalling. Its contents shall be as shown in table 21.57.

**Table 21.57: MAC-FRAG (downlink) PDU contents**

| Information element | Length | Type | Value           | Remark               |
|---------------------|--------|------|-----------------|----------------------|
| MAC PDU type        | 2      | M    | 01 <sub>2</sub> | MAC-FRAG or MAC-END  |
| MAC PDU subtype     | 1      | M    | 0               | MAC-FRAG             |
| Fill bit indication | 1      | M    | 0               | No fill bits present |
|                     |        |      | 1               | Fill bit(s) present  |
| TM-SDU              | varies | M    |                 |                      |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the downlink. A PDU subtype bit distinguishes between MAC-FRAG and MAC-END which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block.

The header length of a MAC-FRAG PDU shall be equal to 4 bits. The maximum TM-SDU length is shown in table 21.58.

**Table 21.58: Maximum length of TM-SDU in downlink MAC-FRAG PDU**

| Logical channel | Maximum TM-SDU length [bits]   |
|-----------------|--|
| SCH/F           | 264  |
| SCH/HD          | 120  |
| SCH-P8/F        | 408  |
| SCH-P8/HD       | 192  |
| SCH-Q/D25-4H    | 181  |
| SCH-Q/D25-16H   | 385  |
| SCH-Q/D25-16U   | 796  |
| SCH-Q/D25-64H   | 589  |
| SCH-Q/D25-64M   | 793  |
| SCH-Q/D25-64U   | 1 204  |
| SCH-Q/D50-4H    | 417  |
| SCH-Q/B50       | 213  |
| SCH-Q/D50-16H   | 857  |
| SCH-Q/D50-16U   | 1 740  |
| SCH-Q/D50-64H   | 1 297  |
| SCH-Q/D50-64M   | 1 737  |
| SCH-Q/D50-64U   | 2 620  |
| SCH-Q/D100-4H   | 889  |
| SCH-Q/B100      | 685  |
| SCH-Q/D100-16H  | 1 801  |
| SCH-Q/D100-16U  | Not normally applicable (see note)   |
| SCH-Q/D100-64H  | Not normally applicable (see note)   |
| SCH-Q/D100-64M  | Not normally applicable (see note)   |
| SCH-Q/D100-64U  | Not normally applicable (see note)   |
| SCH-Q/D150-4H   | 1 361  |
| SCH-Q/B150      | 1 157  |
| SCH-Q/D150-16H  | Not normally applicable (see note)   |
| SCH-Q/D150-16U  | Not normally applicable (see note)   |
| SCH-Q/D150-64H  | Not normally applicable (see note)   |
| SCH-Q/D150-64M  | Not normally applicable (see note)   |
| SCH-Q/D150-64U  | Not normally applicable (see note)   |
| NOTE:           | For these logical channels, the MAC block is large enough to contain the maximum permitted size of TM-SDU so the BS normally has no need to use MAC-FRAG. (It completes the TM-SDU using MAC-END instead.) However the BS may sometimes need to use MAC-FRAG if it chooses to include a fragment of the TM-SDU by association, after sending other PDU(s), such that the TM-SDU cannot be completed within the slot. |

### 21.4.3.3 MAC-END (downlink)

This PDU shall be used to send the last fragment of fragmented C-plane signalling data on the downlink in a full slot (SCH/F, SCH-P8/F or SCH-Q/D) or the first or second half of a full slot (SCH/HD or SCH-P8/HD) or SCH-Q/B. It shall also be used to send the last fragment of fragmented C-plane signalling in the second half of a stolen full slot on the downlink. Its contents shall be as shown in table 21.59.

**Table 21.59: MAC-END (downlink) PDU contents**

| Information element   | Length | Type | Value               | Remark  |
|---|--------|------|---------------------|---|
| MAC PDU type  | 2      | M    | 01 <sub>2</sub>     | MAC-FRAG or MAC-END   |
| MAC PDU subtype   | 1      | M    | 1                   | MAC-END   |
| Fill bit indication   | 1      | M    | 0                   | No fill bits present  |
|   |        |      | 1                   | Fill bit(s) present   |
| Position of grant   | 1      | M    | 0                   | Slot grant is on current channel  |
|   |        |      | 1                   | Slot grant is on allocated channel  |
| Length indication   | 6      | M    | 000000 <sub>2</sub> | Reserved  |
|   |        |      | 000001 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets (see note 1)                    |
|   |        |      | etc.                | etc.  |
|   |        |      | 010010 <sub>2</sub> | Length of MAC PDU = value × Y <sub>2</sub> octets                                 |
|   |        |      | 010011 <sub>2</sub> | Length of MAC PDU = (18 × Y <sub>2</sub> + (value - 18) × Z <sub>2</sub> ) octets |
|   |        |      | etc.                | etc.  |
|   |        |      | 111010 <sub>2</sub> | Length of MAC PDU = (18 × Y <sub>2</sub> + (value - 18) × Z <sub>2</sub> ) octets |
|   |        |      | 111011 <sub>2</sub> | Reserved  |
| Immediate napping permission flag (see note 2)  | 1      | C    | 0                   | Immediate napping permission not given  |
|   |        |      | 1                   | Immediate napping permission given  |
| Slot granting flag  | 1      | M    | 0                   | No slot granting information elements in PDU                                      |
|   |        |      | 1                   | Slot granting information element in PDU  |
| Multiple slot granting flag (see note 3)  | 1      | C    | 0                   | Basic slot granting information element in PDU                                    |
|   |        |      | 1                   | Multiple slot granting information element in PDU                                 |
| Basic slot granting element (see note 4)  | 8      | C    |                     | See basic slot granting information element definition                            |
| Multiple slot granting element (see note 5)   | varies | C    |                     | See multiple slot granting information element definition                         |
| Channel allocation flag   | 1      | M    | 0                   | No channel allocation information element in PDU                                  |
|   |        |      | 1                   | Channel allocation information element in PDU                                     |
| Channel allocation element  | varies | C    |                     | See channel allocation information element definition                             |
| TM-SDU  | varies | C    |                     |   |
| NOTE 1: For values of length indication up to 010010 <sub>2</sub> , the unit of the length indication is Y <sub>2</sub> octets whereas, for higher values, the incremental unit of the length indication is Z <sub>2</sub> octets. The values of Y <sub>2</sub> and Z <sub>2</sub> depend on the bandwidth, modulation and coding rate with which the PDU is sent; the values of Y <sub>2</sub> and Z <sub>2</sub> are given in clause 21.6 for each combination. |        |      |                     |   |
| NOTE 2: The immediate napping permission flag shall be present when the PDU is sent using π/8-D8PSK or QAM modulation. It shall not be present when the PDU is sent using π/4-DQPSK modulation.   |        |      |                     |   |
| NOTE 3: The multiple slot granting flag shall be present when the slot granting flag is set to 1 and the PDU is sent using QAM modulation. It shall not be present when the slot granting flag is set to 0 or the PDU is sent using π/4-DQPSK or π/8-D8PSK modulation.  |        |      |                     |   |
| NOTE 4: The basic slot granting element shall be present when the slot granting flag is set to 1 and either the PDU is sent using π/4-DQPSK or π/8-D8PSK modulation, or the PDU is sent using QAM modulation and the multiple slot granting flag is set to 0.   |        |      |                     |   |
| NOTE 5: The multiple slot granting element shall be present when the slot granting flag is set to 1 and the PDU is sent using QAM modulation and the multiple slot granting flag is set to 1.   |        |      |                     |   |

The first two bits of the MAC header shall distinguish between the possible PDU types which can be sent on the downlink. A PDU subtype bit distinguishes between MAC-FRAG and MAC-END which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block or less than the size of the TM-SDU indicated by the length indication field. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The position of grant element indicates the channel on which the optional slot grant is valid. If there is no slot granting in this PDU, the MAC shall ignore the content of this bit.

The length indication field shall indicate the length of the MAC PDU which comprises the MAC PDU header and the TM-SDU.

The units used for the length indication depend on the bandwidth, modulation and coding rate with which the PDU is sent; see clause 21.6. The defined values of the length indication cover up to the size of the MAC block or the maximum size of a MAC-END PDU, whichever is the lesser.

The immediate napping permission flag shall be present when the PDU is sent using  $\pi/8$ -D8PSK or QAM modulation. This element indicates whether, after receiving this PDU, the MS may regard this address as eligible for napping.

The slot granting flag shall indicate whether one of the optional slot granting elements is present in this PDU. The slot granting element may be used to allocate some uplink reserved slots for an MS. If the slot granting flag is set to 1 then:

- if the PDU is sent using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation, the multiple slot granting flag shall not be present and the basic slot granting element shall be present; or
- if the PDU is sent using QAM modulation, the multiple slot granting flag shall be present; then:
  - if the multiple slot granting flag is set to 0, the basic slot granting element shall be present; or
  - if the multiple slot granting flag is set to 1, the multiple slot granting element shall be present.

The channel allocation flag shall indicate whether the channel allocation element is present in this PDU. The channel allocation element may be used to direct MS to a channel at the end of a fragmented downlink message.

The minimum header length of a MAC-END PDU shall be equal to 13 bits when sent using  $\pi/4$ -DQPSK modulation or 14 bits when sent using  $\pi/8$ -D8PSK or QAM modulation. The maximum TM-SDU length is shown in table 21.60.

**Table 21.60: Maximum length of TM-SDU in downlink MAC-END PDU**

| Logical channel | Maximum TM-SDU length [bits]<br>if no optional fields   |
|-----------------|---|
| SCH/F           | 255   |
| SCH/HD          | 111   |

| SCH-Q/D100-16U  | 2 631 (see note)  |
| SCH-Q/D100-64H  | 2 631 (see note)  |
| SCH-Q/D100-64M  | 2 631 (see note)  |
| SCH-Q/D100-64U  | 2 631 (see note)  |
| SCH-Q/D150-4H   | 1 351   |
| SCH-Q/B150      | 1 147   |
| SCH-Q/D150-16H  | 2 631 (see note)  |
| SCH-Q/D150-16U  | 2 631 (see note)  |
| SCH-Q/D150-64H  | 2 631 (see note)  |
| SCH-Q/D150-64M  | 2 631 (see note)  |
| SCH-Q/D150-64U  | 2 631 (see note)  |
| NOTE:           | The maximum length of TM-SDU in this MAC block is constrained by the maximum permitted size of TM-SDU (N.202) rather than by the size of the MAC block. |

#### 21.4.3.4 MAC-D-BLCK

This PDU may optionally be used to send C-plane signalling data on the downlink in a full slot (SCH/F, SCH-P8/F or SCH-Q/D), or in SCH-Q/B100 or SCH-Q/B150, in cases when an event label can be used and a pre-defined length is appropriate e.g. when sending an advanced link data segment. The MAC-D-BLCK PDU has a smaller MAC header than the MAC-RESOURCE PDU so can carry more data.

The MAC-D-BLCK PDU should not be used when the pre-defined length is not appropriate. For example, when the BS is sending a basic link message or a short advanced link message or the last segment of an advanced link message, use of the MAC-RESOURCE PDU may be more efficient.

The MAC-D-BLCK PDU cannot be used if any of the following functions are needed:

- SSI or SMI addressing;
- fragmentation;
- acknowledgement of random access;
- event label or usage marker assignment;
- power control;

- channel allocation; or
- null PDU.

When any of these functions are needed, the BS should use the MAC-RESOURCE PDU.

The MAC-D-BLCK PDU uses the same MAC PDU type as the MAC-U-SIGNAL PDU, which is sent using the stealing channel (STCH). The MAC-D-BLCK PDU shall not be sent on STCH, SCH/HD or SCH-P8/HD.

The contents of the MAC-D-BLCK PDU shall be as shown in table 21.61.

**Table 21.61: MAC-D-BLCK PDU contents**

| Information element                    | Length | Type | Value           | Remark   |
|--|--------|------|-----------------|--|
| MAC PDU type                           | 2      | M    | 11 <sub>2</sub> | Supplementary MAC PDU                                  |
| Supplementary MAC PDU subtype          | 1      | M    | 0               | MAC-D-BLCK   |
| Fill bit indication                    | 1      | M    | 0               | No fill bit present                                    |
|  |        |      | 1               | Fill bit(s) present                                    |
| Encryption mode                        | 2      | M    | 00 <sub>2</sub> | Not encrypted  |
|  |        |      | 01 <sub>2</sub> | See ETSI EN 300 392-7 [8]                              |
|  |        |      | 10 <sub>2</sub> | See ETSI EN 300 392-7 [8]                              |
|  |        |      | 11 <sub>2</sub> | See ETSI EN 300 392-7 [8]                              |
| Address                                | 10     | M    |                 | Event label  |
| Immediate napping permission flag      | 1      | M    | 0               | Immediate napping permission not given                 |
|  |        |      | 1               | Immediate napping permission given                     |
| Slot granting flag.                    | 1      | M    | 0               | No slot granting information element in PDU            |
|  |        |      | 1               | Slot granting information element in PDU               |
| Basic slot granting element (see note) | 8      | C    |                 | See basic slot granting information element definition |
| TM-SDU                                 | varies | C    |                 |  |

NOTE: The basic slot granting element shall be present when the slot granting flag is set to 1.

The length of the MAC-D-BLCK PDU is defined implicitly, as shown in table 21.62. The implicit length shall refer to the length of the MAC PDU, which comprises the MAC PDU header and the TM-SDU. For a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK slot, the implicit length matches the size of the MAC block. On a QAM channel, the implicit length of the MAC-D-BLCK PDU is set to correspond to the normal size of an advanced link data segment i.e.:

- in the case of a 25 kHz or 50 kHz channel, the implicit length corresponds to the size of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth;
- in the case of a 100 kHz or 150 kHz channel, the implicit length corresponds to half the size of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth.

**Table 21.62: Implicit length of MAC-D-BLCK PDU**

| Logical channel        | Implicit length of MAC-D-BLCK PDU |
|------------------------|-----------------------------------|
| SCH/F                  | 268 bits                          |
| SCH-P8/F               | 412 bits                          |
| SCH-Q/D25              | 185 bits                          |
| SCH-Q/D50              | 421 bits                          |
| SCH-Q/D100, SCH-Q/B100 | 446 bits                          |
| SCH-Q/D150, SCH-Q/B150 | 682 bits                          |

The first two bits of the MAC header distinguish between the possible PDU types which can be sent on the downlink SCH/F, SCH-P8/F, SCH-Q/D, SCH-Q/B100 or SCH-Q/B150. The supplementary MAC PDU subtype bit distinguishes between supplementary MAC PDUs which share the same MAC PDU type.

The fill bit indication shall indicate if there are any fill bits, which shall be added whenever the size of the TM-SDU is less than the available capacity of the MAC block or less than the size of the TM-SDU indicated by the implicit length of the MAC-D-BLCK PDU. The TM-SDU length is equal to the MAC PDU length minus the MAC PDU header length.

The encryption mode field shall indicate whether or not the TM-SDU contents are encrypted and, if so, the encryption algorithm used. The MAC header shall not be encrypted.

The address field shall contain an event label.

NOTE 1: As defined in ETSI EN 300 392-7 [8], the event label is not encrypted.

The immediate napping permission flag shall indicate whether, after receiving this PDU, the MS may regard this address as eligible for napping.

The slot granting flag shall indicate whether the optional basic slot granting element is present in this PDU.

NOTE 2: The BS may cut an advanced link TL-SDU into segments using the assumption that it will not include a slot grant until the end of the TL-SDU. Alternatively it may cut the TL-SDU into segments allowing for a possible slot grant and then include fill bits when the basic slot granting element is not present.

The header length of a MAC-D-BLCK PDU shall be equal to 18 bits if a basic slot granting element is not included. The maximum TM-SDU length is shown in table 21.63.

**Table 21.63: Maximum length of TM-SDU in MAC-D-BLCK PDU**

| Logical channel        | Maximum TM-SDU length [bits] |
|------------------------|------------------------------|
| SCH/F                  | 250                          |
| SCH-P8/F               | 394                          |
| SCH-Q/D25              | 167                          |
| SCH-Q/D50              | 403                          |
| SCH-Q/D100, SCH-Q/B100 | 428                          |
| SCH-Q/D150, SCH-Q/B150 | 664                          |

## 21.4.4 TMB-SAP: MAC PDU structure for broadcast

### 21.4.4.0 General

Broadcast PDUs shall be used by the BS to send some broadcast information on the downlink to all MSs. There shall be no addresses contained in these PDUs and all MSs shall decode them as if they were addressed to each of them. The SYNC PDU shall be transmitted using the BSCH which shall be sent using the phase modulation synchronization burst. The SYNC-DA PDU shall be transmitted using the BSCH-Q which shall be sent using the QAM frequency correction burst.

There is no PDU type element in the SYNC PDU and SYNC-DA PDU. The other broadcast PDU types shall be distinguished by a PDU type and broadcast type as shown in table 21.64.

**Table 21.64: Broadcast PDU contents**

| Information element | Length | Type | Value           | Remark  |
|---------------------|--------|------|-----------------|---|
| MAC PDU type        | 2      | M    | 10 <sub>2</sub> | Broadcast PDU   |
| Broadcast type      | 2      | M    | 00 <sub>2</sub> | SYSINFO PDU if sent using $\pi/4$ -DQPSK modulation or $\pi/8$ -D8PSK modulation; or SYSINFO-Q PDU if sent using QAM modulation |
|                     |        |      | 01 <sub>2</sub> | ACCESS-DEFINE PDU   |
|                     |        |      | 10 <sub>2</sub> | SYSINFO-DA  |
|                     |        |      | 11 <sub>2</sub> | Reserved  |
| Broadcast elements  |        |      |                 | See following definitions for SYSINFO, SYSINFO-Q, SYSINFO-DA and ACCESS-DEFINE PDUs   |

The following clauses describe the contents of the three types of broadcast PDU.

### 21.4.4.1 SYSINFO

The SYSINFO PDU shall be transmitted using the BNCH on SCH/HD. It may also be sent using the stealing channel (STCH). It may also be sent using association on SCH-P8/HD or SCH-P8/F. Its contents shall be as shown in table 21.65.

NOTE 1: The SYSINFO PDU is sent on  $\pi/4$ -DQPSK and  $\pi/8$ -D8PSK channels. It is sent using  $\pi/4$ -DQPSK modulation on  $\pi/4$ -DQPSK channels. It is also sent using  $\pi/4$ -DQPSK modulation on  $\pi/8$ -D8PSK channels according to a mandatory mapping, but it may be sent using either  $\pi/4$ -DQPSK modulation or  $\pi/8$ -D8PSK modulation in other positions.

**Table 21.65: SYSINFO PDU contents**

| Information element   | Length | Type | Value             | Remark   |
|---|--------|------|-------------------|--|
| MAC PDU type  | 2      | M    | 10 <sub>2</sub>   | Broadcast PDU  |
| Broadcast type  | 2      | M    | 00 <sub>2</sub>   | SYSINFO PDU  |
| Main carrier  | 12     | M    |                   | Frequency of the CA main carrier (see note 3)  |
| Frequency band  | 4      | M    |                   | Frequency band of the CA main carrier (see note 3)   |
| Offset  | 2      | M    | 00 <sub>2</sub>   | 0 kHz offset   |
|   |        |      | 01 <sub>2</sub>   | +6,25 kHz offset   |
|   |        |      | 10 <sub>2</sub>   | -6,25 kHz offset   |
|   |        |      | 11 <sub>2</sub>   | +12,5 kHz offset   |
| Duplex spacing  | 3      | M    |                   | Provision for different duplex spacing   |
| Reverse operation   | 1      | M    | 0                 | Normal   |
|   |        |      | 1                 | Reverse  |
| Number of common secondary control channels in use on CA main carrier | 2      | M    | 00 <sub>2</sub>   | None   |
|   |        |      | 01 <sub>2</sub>   | Timeslot 2 of main carrier   |
|   |        |      | 10 <sub>2</sub>   | Timeslots 2 and 3 of main carrier  |
|   |        |      | 11 <sub>2</sub>   | Timeslots 2, 3 and 4 of main carrier   |
| MS_TXPWR_MAX_CELL (see note 1)  | 3      | M    | 000 <sub>2</sub>  | Reserved   |
|   |        |      | 001 <sub>2</sub>  | 15 dBm   |
|   |        |      | etc.              | etc. in 5 dB steps   |
|   |        |      | 111 <sub>2</sub>  | 45 dBm   |
| RXLEV_ACCESS_MIN (see note 1)   | 4      | M    | 0000 <sub>2</sub> | -125 dBm   |
|   |        |      | etc.              | etc. in 5 dB steps   |
|   |        |      | 1111 <sub>2</sub> | -50 dBm  |
| ACCESS_PARAMETER (see note 1)   | 4      | M    | 0000 <sub>2</sub> | -53 dBm  |
|   |        |      | etc.              | etc. in 2 dB steps   |
|   |        |      | 1111 <sub>2</sub> | -23 dBm  |
| RADIO_DOWNLINK_TIMEOUT (see note 1)                                   | 4      | M    | 0000 <sub>2</sub> | Disable radio downlink counter   |
|   |        |      | 0001 <sub>2</sub> | 144 timeslots  |
|   |        |      | 0010 <sub>2</sub> | 288 timeslots  |
|   |        |      | etc.              | etc. in multiples of 144   |
|   |        |      | 1111 <sub>2</sub> | 2 160 timeslots  |
| Hyperframe / cipher key flag  | 1      | M    | 0                 | Hyperframe number  |
|   |        |      | 1                 | Common cipher key identifier   |
| Hyperframe number   | 16     | C    |                   | Cyclic count of hyperframes  |
| CCK identifier or static cipher key version number                    | 16     | C    |                   | Common cipher key identifier or static cipher key version number, refer to ETSI EN 300 392-7 [8] |
| Optional field flag   | 2      | M    | 00 <sub>2</sub>   | Even multiframe definition for TS mode   |
|   |        |      | 01 <sub>2</sub>   | Odd multiframe definition for TS mode  |
|   |        |      | 10 <sub>2</sub>   | Default definition for access code A   |
|   |        |      | 11 <sub>2</sub>   | Extended services broadcast  |
| TS_COMMON_FRAMES either for Even or Odd multiframes                   | 20     | C    |                   | Bit map of common frames for TS mode, see information element description in table 21.94         |
| Default definition for access code A                                  | 20     | C    |                   | See table 21.66  |
| Extended services broadcast   | 20     | C    |                   | See table 21.67  |

| Information element   | Length | Type | Value | Remark                                    |
|---|--------|------|-------|---|
| Reserved (see note 2)   | 28     | C    |       | Reserved, value shall be set to all zeros |
| TM-SDU (MLE data)   | 42     | M    |       | As defined in clause 18 (D-MLE-SYSINFO)   |
| NOTE 1: When sent on a D8PSK channel, the value of this element is specific to that D8PSK channel and may be different from the value for a $\pi/4$ -DQPSK channel.                 |        |      |       |   |
| NOTE 2: This element shall be present when the PDU is sent using $\pi/8$ -D8PSK modulation. This element shall not be present when the PDU is sent using $\pi/4$ -DQPSK modulation. |        |      |       |   |
| NOTE 3: If there is no CA main carrier, the parameters Main carrier and Frequency band are set to 0.  |        |      |       |   |

The frequency of the conventional access main carrier shall be defined by the following information elements:

- main carrier;
- frequency band;
- offset;
- duplex spacing;
- reverse operation.

The frequency band field shall map to a specific frequency which shall map to a defined base frequency (in MHz) for the carrier numbering scheme. The main carrier field shall indicate the carrier frequency relative to the base frequency defined by the frequency band field. The main carrier field shall have step size of 25 kHz. The offset field shall then adjust the main carrier frequency by the given amount. (The offset field allows for the case where the carrier frequency is not  $N \times 25$  kHz above the base frequency.) The frequency so defined shall be the downlink frequency of the main carrier. This calculation is summarized by the following equation:

- downlink main carrier frequency = base frequency + (main carrier  $\times$  25 kHz) + offset kHz.

The uplink frequency of the main carrier shall be determined using the duplex spacing and reverse operation fields. The duplex spacing field shall map to a defined duplex spacing (in MHz) for the carrier numbering scheme. The duplex spacing shall be dependent on the frequency band element. The reverse operation field shall indicate whether to add or subtract the duplex spacing to arrive at the uplink frequency of the main carrier. If normal operation, the duplex spacing shall be subtracted. If reverse operation, the duplex spacing shall be added. This calculation is summarized by the following equations:

- normal operation:
  - uplink main carrier frequency = downlink main carrier frequency - duplex spacing.
- reverse operation:
  - uplink main carrier frequency = downlink main carrier frequency + duplex spacing.

The mappings of the frequency band field values to actual base frequencies and the duplex spacing field values to actual duplex frequency spacing are defined in ETSI TS 100 392-15 [18].

NOTE 2: These rules for calculation of uplink and downlink carrier frequency are also used for calculation of the uplink and downlink main carrier frequency from the elements in the SYSINFO-Q PDU.

RXLEV\_ACCESS\_MIN shall be used for cell selection and reselection. ACCESS\_PARAMETER shall be used for subsequent power adjustments. MS\_TXPWR\_MAX\_CELL shall be used for cell selection and reselection, and for power adjustments. RADIO\_DOWNLINK\_TIMEOUT shall be used in the criteria for radio downlink failure.

The hyperframe/cipher key flag shall indicate whether the following information element is the hyperframe number information element or the CCK identifier or static cipher key version number information element. The usage of the CCK identifier or static cipher key version number information element is defined in ETSI EN 300 392-7 [8].

The optional field flag information element indicates which one of the optional information elements is present.

The TS\_COMMON\_FRAMES information element shall only be present if "Discontinuous TX" and "MCCH sharing" is indicated in the SYNC broadcast PDU. The optional field shall indicate whether TS\_COMMON\_FRAMES refers to odd or even multiframe definition.

If the optional field flag indicates a default access definition, then the 20-bit field corresponding to the default access code definition for access code A shall be present. Its contents shall be as defined in table 21.66.

**Table 21.66: Default definition for access code A information element contents**

| Information element                                  | Length | Type | Value             | Remark                                    |
|--|--------|------|-------------------|---|
| IMM (immediate)                                      | 4      | M    | 0000 <sub>2</sub> | Always randomize                          |
|  |        |      | 0001 <sub>2</sub> | Randomize after IMM TDMA frames           |
|  |        |      | etc.              | etc.                                      |
|  |        |      | 1110 <sub>2</sub> | Randomize after IMM TDMA frames           |
|  |        |      | 1111 <sub>2</sub> | Immediate access allowed                  |
| WT (waiting time)                                    | 4      | M    | 0000 <sub>2</sub> | Reserved                                  |
|  |        |      | 0001 <sub>2</sub> | Response within WT downlink opportunities |
|  |        |      | etc.              | etc.                                      |
|  |        |      | 1111 <sub>2</sub> | Response within WT downlink opportunities |
| Nu (number of random access transmissions on uplink) | 4      | M    | 0000 <sub>2</sub> | No random access transmission allowed     |
|  |        |      | 0001 <sub>2</sub> | 1 random access transmission allowed      |
|  |        |      | etc.              | etc.                                      |
|  |        |      | 1111 <sub>2</sub> | 15 random access transmissions allowed    |
| Frame-length factor                                  | 1      | M    | 0                 | Multiply base frame-length by 1           |
|  |        |      | 1                 | Multiply base frame-length by 4           |
| Timeslot pointer                                     | 4      | M    | 0000 <sub>2</sub> | Same as downlink slot assignment          |
|  |        |      | 0001 <sub>2</sub> | Timeslot 4                                |
|  |        |      | 0010 <sub>2</sub> | Timeslot bit map                          |
|  |        |      | etc.              | etc.                                      |
|  |        |      | 1110 <sub>2</sub> | Timeslot bit map                          |
|  |        |      | 1111 <sub>2</sub> | All four timeslots                        |
| Minimum PDU priority                                 | 3      | M    | 000 <sub>2</sub>  | Priority 0 (lowest)                       |
|  |        |      | etc.              | etc.                                      |
|  |        |      | 111 <sub>2</sub>  | Priority 7 (highest)                      |

If optional field flag indicates an extended service broadcast, the bits shall be used to indicate the extended services provided according to table 21.67. In the present document only the extended services broadcast sections 1 and 2 may be used.

NOTE 3: The extended services broadcast sections 3 and 4 are not used in the present document. The setting of the reserved bits to 0000000<sub>2</sub> in tables 21.70 and 21.71 does not limit how those bits will be used in future editions of the present document.

**Table 21.67: Extended services broadcast information element contents**

| Information element  | Length | M/C/O | Value           | Remark  |
|--|--------|-------|-----------------|---|
| Security information   | 8      |       |                 | Refer to ETSI EN 300 392-7 [8].                         |
| SDS-TL addressing method   | 2      | M     | 00 <sub>2</sub> | Reserved  |
|  |        |       | 01 <sub>2</sub> | Service centre addressing preferred (see note 1)        |
|  |        |       | 10 <sub>2</sub> | Never use service centre addressing (see note 1)        |
|  |        |       | 11 <sub>2</sub> | MS choice to use service centre addressing (see note 1) |
| GCK supported  | 1      | M     |                 | Refer to ETSI EN 300 392-7 [8] (see note 2)             |
| Section  | 2      | M     | 00 <sub>2</sub> | Extended services broadcast section 1 is present        |
|  |        |       | 01 <sub>2</sub> | Extended services broadcast section 2 is present        |
|  |        |       | 10 <sub>2</sub> | Extended services broadcast section 3 is present        |
|  |        |       | 11 <sub>2</sub> | Extended services broadcast section 4 is present        |
| Extended services broadcast section 1 (see note 3)   | 7      | C     |                 | See table 21.68   |
| Extended services broadcast section 2 (see note 4)   | 7      | C     |                 | See table 21.69   |
| Extended services broadcast section 3 (see note 5)   | 7      | C     |                 | See table 21.70   |
| Extended services broadcast section 4 (see note 6)   | 7      | C     |                 | See table 21.71   |
| NOTE 1: Refer to clause 29 for further information.  |        |       |                 |   |
| NOTE 2: This shall be ignored by the MS when AI encryption is not available (indicated in BS Service Details). |        |       |                 |   |
| NOTE 3: This element shall be present only if section element is set to 00 <sub>2</sub> .                      |        |       |                 |   |
| NOTE 4: This element shall be present only if section element is set to 01 <sub>2</sub> .                      |        |       |                 |   |
| NOTE 5: This element shall be present only if section element is set to 10 <sub>2</sub> .                      |        |       |                 |   |
| NOTE 6: This element shall be present only if section element is set to 11 <sub>2</sub> .                      |        |       |                 |   |

**Table 21.68: Extended services broadcast section 1 information element contents**

| Information element   | Length | M/C/O | Value | Remark   |
|---|--------|-------|-------|--|
| Data priority supported   | 1      | M     | 0     | Data priority not supported on this cell   |
|   |        |       | 1     | Data priority supported on this cell   |
| Extended advanced links and MAC-U-BLCK supported  | 1      | M     | 0     | Extended advanced links and MAC-U-BLCK PDU not supported on this cell (see note 1) |
|   |        |       | 1     | Extended advanced links and MAC-U-BLCK PDU supported on this cell (see note 2)     |
| QoS negotiation supported (see note 3)  | 1      | M     | 0     | QoS negotiation not supported on this cell   |
|   |        |       | 1     | QoS negotiation supported on this cell   |
| D8PSK service   | 1      | M     | 0     | D8PSK operation not supported on this cell   |
|   |        |       | 1     | D8PSK operation supported on this cell   |
| Section 2 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 2                            |
|   |        |       | 1     | Further information in extended services broadcast section 2                       |
| Section 3 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 3                            |
|   |        |       | 1     | Further information in extended services broadcast section 3                       |
| Section 4 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 4                            |
|   |        |       | 1     | Further information in extended services broadcast section 4                       |
| NOTE 1: If the "extended advanced links and MAC-U-BLCK supported" element is set to 0, this indicates that the BS does not support extended advanced links and does not support the MAC-U-BLCK PDU. The BS may support the original advanced link (see the "BS service details" element in clause 18.5.2).  |        |       |       |  |
| NOTE 2: If the "extended advanced links and MAC-U-BLCK supported" element is set to 1, this indicates that the BS supports four extended advanced links for each service and for each MS address, and supports the original advanced link plus three extended advanced links for each service and for each MS address; it also indicates that the BS supports the MAC-U-BLCK PDU (if it has assigned an event label to the MS). |        |       |       |  |
| NOTE 3: Cells that support D8PSK and/or QAM operation shall support QoS negotiation.  |        |       |       |  |

**Table 21.69: Extended services broadcast section 2 information element contents**

| Information element | Length | M/C/O | Value | Remark   |
|---------------------|--------|-------|-------|--|
| 25 kHz QAM service  | 1      | M     | 0     | 25 kHz QAM operation not supported on this cell  |
|                     |        |       | 1     | 25 kHz QAM operation supported on this cell      |
| 50 kHz QAM service  | 1      | M     | 0     | 50 kHz QAM operation not supported on this cell  |
|                     |        |       | 1     | 50 kHz QAM operation supported on this cell      |
| 100 kHz QAM service | 1      | M     | 0     | 100 kHz QAM operation not supported on this cell |
|                     |        |       | 1     | 100 kHz QAM operation supported on this cell     |
| 150 kHz QAM service | 1      | M     | 0     | 150 kHz QAM operation not supported on this cell |
|                     |        |       | 1     | 150 kHz QAM operation supported on this cell     |
| Reserved            | 3      | M     |       | Reserved, value shall be set to 000 <sub>2</sub> |

**Table 21.70: Extended services broadcast section 3 information element contents**

| Information element | Length | M/C/O | Value | Remark   |
|---------------------|--------|-------|-------|--|
| Reserved            | 7      | M     |       | Reserved, value shall be set to 0000000 <sub>2</sub> |

**Table 21.71: Extended services broadcast section 4 information element contents**

| Information element | Length | M/C/O | Value | Remark   |
|---------------------|--------|-------|-------|--|
| Reserved            | 7      | M     |       | Reserved, value shall be set to 0000000 <sub>2</sub> |

Each of the optional fields comprises 20 bits (including reserved bits). Therefore, when the SYSINFO PDU is sent using  $\pi/4$ -DQPSK modulation, it fully occupies all 124 bits of the MAC block in all cases.

When the SYSINFO PDU is sent using  $\pi/8$ -D8PSK modulation, there is an additional reserved element. Therefore, when the SYSINFO PDU is sent using  $\pi/8$ -D8PSK modulation, the PDU length is 152 bits.

#### 21.4.4.1a SYSINFO-Q

The SYSINFO-Q PDU may be transmitted by the BS to send broadcast information on a QAM channel to conventional access MSs.

The SYSINFO-Q PDU shall use the BNCH-Q on SCH-Q/D. It fully occupies a 4-QAM rate = 1/2 SCH-Q/D MAC block on a 25 kHz QAM channel (logical channel SCH-Q/D25-4H). It may be sent using PDU association within other SCH-Q/D MAC blocks (i.e. higher modulation level and/or bandwidth). Its contents shall be as shown in table 21.72.

NOTE 1: The SYSINFO-Q PDU may be sent on QAM channels. It is always sent using QAM modulation.

Table 21.72: SYSINFO-Q PDU contents

| Information element   | Length | Type | Value             | Remark   |
|---|--------|------|-------------------|--|
| MAC PDU type  | 2      | M    | 10 <sub>2</sub>   | Broadcast PDU  |
| Broadcast type  | 2      | M    | 00 <sub>2</sub>   | SYSINFO-Q PDU  |
| Main carrier  | 12     | M    |                   | Frequency of the CA main carrier   |
| Frequency band  | 4      | M    |                   | Frequency band of the CA main carrier  |
| Offset  | 2      | M    | 00 <sub>2</sub>   | 0 kHz offset   |
|   |        |      | 01 <sub>2</sub>   | +6,25 kHz offset   |
|   |        |      | 10 <sub>2</sub>   | -6,25 kHz offset   |
|   |        |      | 11 <sub>2</sub>   | +12,5 kHz offset   |
| Duplex spacing  | 3      | M    |                   | Provision for different duplex spacing   |
| Reverse operation   | 1      | M    | 0                 | Normal   |
|   |        |      | 1                 | Reverse  |
| Number of common secondary control channels in use on CA main carrier           | 2      | M    | 00 <sub>2</sub>   | None   |
|   |        |      | 01 <sub>2</sub>   | Timeslot 2 of main carrier   |
|   |        |      | 10 <sub>2</sub>   | Timeslots 2 and 3 of main carrier  |
|   |        |      | 11 <sub>2</sub>   | Timeslots 2, 3 and 4 of main carrier   |
| MS_TXPWR_MAX_CELL on this QAM carrier   | 3      | M    | 000 <sub>2</sub>  | Reserved   |
|   |        |      | 001 <sub>2</sub>  | 15 dBm   |
|   |        |      | etc.              | etc. in 5 dB steps   |
|   |        |      | 111 <sub>2</sub>  | 45 dBm   |
| RXLEV_ACCESS_MIN on this QAM carrier  | 4      | M    | 0000 <sub>2</sub> | -125 dBm   |
|   |        |      | etc.              | etc. in 5 dB steps   |
|   |        |      | 1111 <sub>2</sub> | -50 dBm  |
| ACCESS_PARAMETER on this QAM carrier  | 4      | M    | 0000 <sub>2</sub> | -53 dBm  |
|   |        |      | etc.              | etc. in 2 dB steps   |
|   |        |      | 1111 <sub>2</sub> | -23 dBm  |
| RADIO_DOWNLINK_TIMEOUT on this QAM carrier                                      | 4      | M    | 0000 <sub>2</sub> | Disable radio downlink counter   |
|   |        |      | 0001 <sub>2</sub> | 144 timeslots  |
|   |        |      | 0010 <sub>2</sub> | 288 timeslots  |
|   |        |      | etc.              | etc. in multiples of 144   |
|   |        |      | 1111 <sub>2</sub> | 2 160 timeslots  |
| CCK identifier or static cipher key version number (see note)                   | 16     | M    |                   | Common cipher key identifier or static cipher key version number, refer to ETSI EN 300 392-7 [8] |
| Default definition for access code A  | 20     | M    |                   | See table 21.66  |
| Extended services broadcast   | 20     | M    |                   | See table 21.67  |
| Reserved  | 39     | M    |                   | Reserved, value shall be set to all zeros  |
| TM-SDU (MLE data)   | 47     | M    |                   | As defined in clause 18 (D-MLE-SYSINFO-Q)  |
| NOTE: This element has no meaning if Air Interface Encryption is not supported. |        |      |                   |  |

NOTE 2: SYSINFO-Q PDU is not sent, if there is no CA main carrier.

The frequency of the conventional access main carrier shall be defined by the following information elements:

- main carrier;
- frequency band;
- offset;
- duplex spacing;
- reverse operation.

The downlink and uplink main carrier frequency shall be calculated using the same equations as defined for the main carrier frequency calculation in the SYSINFO PDU description; see clause 21.4.4.1.

RXLEV\_ACCESS\_MIN shall be used in the calculation of the path loss on the QAM channel.  
 ACCESS\_PARAMETER shall be used for power adjustments on the QAM channel. MS\_TXPWR\_MAX\_CELL shall be used in the calculation of the path loss on the QAM channel, and for power adjustments on the QAM channel.  
 RADIO\_DOWNLINK\_TIMEOUT shall be used in the criteria for radio downlink failure of the QAM channel.

The usage of the CCK identifier or static cipher key version number information element is defined in ETSI EN 300 392-7 [8].

The contents of the default definition for access code A information element shall be as defined in table 21.66.

The contents of the extended services broadcast information element shall be as defined in table 21.67.

The size of the SYSINFO-Q PDU is 185 bits. Therefore, when the SYSINFO-Q PDU is sent using 4-QAM rate = 1/2 on a 25 kHz channel, it fully occupies all 185 bits of the MAC block (SCH-Q/D25-4H). When the SYSINFO-Q PDU is sent using a higher modulation level and/or bandwidth, it may be sent with other PDU(s) in the SCH-Q/D MAC block using PDU association.

#### 21.4.4.1b SYSINFO-DA

The SYSINFO-DA PDU may be transmitted by the BS to send broadcast information on a QAM channel to direct access MSs.

The SYSINFO-DA PDU shall use the BNCH-Q on SCH-Q/D or on SCH-Q/B. The SYSINFO-DA PDU fully occupies a 4-QAM rate = 1/2 SCH-Q/D MAC block on a 25 kHz QAM channel (logical channel SCH-Q/D25-4H). It may be sent using PDU association within other SCH-Q/D MAC blocks (i.e. higher modulation level and/or bandwidth) or within SCH-Q/B MAC blocks. Its contents shall be as shown in table 21.73.

The SYSINFO-DA PDU shall be sent on the DA main carrier and may be sent on QAM carriers other than the DA main carrier.

The SYSINFO-DA PDU may be transmitted on phase modulated channels using PDU association on SCH/F or SCH-P8/F or using SCH-P8/HD.

**Table 21.73: SYSINFO-DA PDU contents**

| Information element   | Length | Type | Value            | Remark  |
|---|--------|------|------------------|---|
| MAC PDU type  | 2      | M    | 10 <sub>2</sub>  | Broadcast PDU   |
| Broadcast type  | 2      | M    | 10 <sub>2</sub>  | SYSINFO-DA PDU  |
| DA main carrier bandwidth                                       | 3      | M    | 000 <sub>2</sub> | 25 kHz  |
|   |        |      | 001 <sub>2</sub> | 50 kHz  |
|   |        |      | 010 <sub>2</sub> | 100 kHz   |
|   |        |      | 011 <sub>2</sub> | 150 kHz   |
|   |        |      | 100 <sub>2</sub> | Reserved  |
|   |        |      | etc.             | etc.  |
|   |        |      | 111 <sub>2</sub> | Reserved  |
| DA main carrier   | 12     | M    |                  | Frequency of the DA main carrier                            |
| Frequency band  | 4      | M    |                  | Frequency band of the DA main carrier                       |
| Offset  | 2      | M    | 00 <sub>2</sub>  | 0 kHz offset  |
|   |        |      | 01 <sub>2</sub>  | +6,25 kHz offset  |
|   |        |      | 10 <sub>2</sub>  | -6,25 kHz offset  |
|   |        |      | 11 <sub>2</sub>  | +12,5 kHz offset  |
| Duplex spacing  | 3      | M    |                  | Provision for different duplex spacing                      |
| Reverse operation   | 1      | M    | 0                | Normal  |

| TM-SDU (MLE data)  | 47     | M    |                   | As defined in clause 18 (D-MLE-SYSINFO-DA)   |

| Information element | Length | Type | Value | Remark  |
|---------------------|--------|------|-------|---|
| NOTE 1:             |        |      |       | This element is present only when element "Usage of common control channel slots on DA main carrier" is set to 0.                                       |
| NOTE 2:             |        |      |       | This element is present only when element "Usage of common control channel slots on DA main carrier" is set to 1.                                       |
| NOTE 3:             |        |      |       | This element is present only when the SYSINFO-DA PDU is sent using QAM modulation.  |
| NOTE 4:             |        |      |       | This element is present only when the SYSINFO-DA PDU is sent using $\pi/4$ -DQPSK or $\pi/8$ -D8PSK modulation.   |
| NOTE 5:             |        |      |       | This element has no meaning if Air Interface Encryption is not supported.   |
| NOTE 6:             |        |      |       | If the MS does not understand the value of this element, it shall regard the value as indicating the maximum QAM modulation level supported by that MS. |

The frequency of the DA main carrier shall be defined by the following information elements:

- DA main carrier;
- channel bandwidth;
- frequency band;
- offset;
- duplex spacing;
- reverse operation.

The frequency band field shall map to a specific frequency which shall map to a defined base frequency (in MHz) for the carrier numbering scheme. The DA main carrier field shall indicate the carrier frequency relative to the base frequency defined by the frequency band field. The DA main carrier field shall have step size of 25 kHz. The offset field shall then adjust the DA main carrier frequency by the given amount. The frequency so defined shall be the downlink frequency of the DA main carrier, but with an additional term to allow bandwidths greater than 25 kHz. This calculation is summarized by the following equation:

$$\text{downlink main carrier frequency} = \text{base frequency} + (\text{DA main carrier} \times 25 \text{ kHz}) + \text{offset kHz} \\ + ( (\text{DA main carrier bandwidth} / 2) - 12,5 ) \text{ kHz}$$

The uplink frequency of the main carrier shall be determined using the duplex spacing and reverse operation fields. The duplex spacing field shall map to a defined duplex spacing (in MHz) for the carrier numbering scheme. The duplex spacing shall be dependent on the frequency band element. The reverse operation field shall indicate whether to add or subtract the duplex spacing to arrive at the uplink frequency of the main carrier. If normal operation, the duplex spacing shall be subtracted. If reverse operation, the duplex spacing shall be added. This calculation is summarized by the following equations:

- normal operation:
  - uplink main carrier frequency = downlink main carrier frequency - duplex spacing
- reverse operation:
  - uplink main carrier frequency = downlink main carrier frequency + duplex spacing.

The mappings of the frequency band field values to actual base frequencies and the duplex spacing field values to actual duplex frequency spacing are defined in ETSI TS 100 392-15 [18].

NOTE: For bandwidths greater than 25 kHz, the carrier number refers to the centre frequency of the lowest 25 kHz comprising the DA main carrier. The final term (relating to the bandwidth) in the equation for the downlink main carrier frequency then generates the centre frequency of the DA main carrier.

RXLEV\_ACCESS\_MIN shall be used in the calculation of the path loss on the QAM channel.

ACCESS\_PARAMETER shall be used for power adjustments on the QAM channel. MS\_TXPWR\_MAX\_CELL shall be used in the calculation of the path loss on the QAM channel, and for power adjustments on the QAM channel.

RADIO\_DOWNLINK\_TIMEOUT shall be used in the criteria for radio downlink failure of the QAM channel.

The usage of the CCK identifier or static cipher key version number information element is defined in ETSI EN 300 392-7 [8].

The contents of the default definition for access code A information element shall be as defined in table 21.66.

The contents of the extended DA services broadcast information element shall be as defined in table 21.74.

The size of the SYSINFO-DA PDU is 185 bits. Therefore, when the SYSINFO-DA PDU is sent using 4-QAM rate = 1/2 on a 25 kHz channel, it fully occupies all 185 bits of the MAC block (SCH-Q/D25-4H). When the SYSINFO-DA PDU is sent using a higher modulation level and/or bandwidth, it may be sent with other PDU(s) in the SCH-Q/D or SCH-Q/B MAC block using PDU association. When the SYSINFO-DA PDU is transmitted on a phase modulated channel, it may be sent with other PDU(s) in an SCH/F or SCH-P8/F MAC block using PDU association.

**Table 21.74: Extended DA services broadcast information element contents**

| Information element   | Length | M/C/O | Value           | Remark  |
|---|--------|-------|-----------------|---|
| Security information  | 8      |       |                 | Refer to ETSI EN 300 392-7 [8].                         |
| SDS-TL addressing method  | 2      | M     | 00 <sub>2</sub> | Reserved  |
|   |        |       | 01 <sub>2</sub> | Service centre addressing preferred (see note 1)        |
|   |        |       | 10 <sub>2</sub> | Never use service centre addressing (see note 1)        |
|   |        |       | 11 <sub>2</sub> | MS choice to use service centre addressing (see note 1) |
| GCK supported   | 1      | M     |                 | Refer to ETSI EN 300 392-7 [8] (see note 2)             |
| Section   | 2      | M     | 00 <sub>2</sub> | Extended services broadcast section 1da is present      |

| Extended services broadcast section 1da (see note 3)  | 7      | C     |                 | See table 21.75   |
| Extended services broadcast section 2 (see note 4)  | 7      | C     |                 | See table 21.69   |
| Extended services broadcast section 3 (see note 5)  | 7      | C     |                 | See table 21.70   |
| Extended services broadcast section 4 (see note 6)  | 7      | C     |                 | See table 21.71   |
| NOTE 1: Refer to clause 29 for further information.   |        |       |                 |   |
| NOTE 2: This shall be ignored by the MS when AI encryption is not available (indicated in BS Service Details DA). |        |       |                 |   |
| NOTE 3: This element shall be present only if section element is set to 00 <sub>2</sub> .                         |        |       |                 |   |
| NOTE 4: This element shall be present only if section element is set to 01 <sub>2</sub> .                         |        |       |                 |   |
| NOTE 5: This element shall be present only if section element is set to 10 <sub>2</sub> .                         |        |       |                 |   |
| NOTE 6: This element shall be present only if section element is set to 11 <sub>2</sub> .                         |        |       |                 |   |

**Table 21.75: Extended services broadcast section 1da information element contents**

| Information element   | Length | M/C/O | Value | Remark   |
|---|--------|-------|-------|--|
| Data priority supported   | 1      | M     | 0     | Data priority not supported on this cell                       |
|   |        |       | 1     | Data priority supported on this cell                           |
| Reserved  | 1      | M     | 0     | Reserved for further use. Default value 0.                     |
| $\pi/4$ -DQPSK Packet Data service supported  | 1      | M     | 0     | $\pi/4$ -DQPSK Packet Data service not supported on this cell. |
|   |        |       | 1     | $\pi/4$ -DQPSK Packet Data service supported on this cell.     |
| D8PSK service   | 1      | M     | 0     | D8PSK operation not supported on this cell                     |
|   |        |       | 1     | D8PSK operation supported on this cell                         |
| Section 2 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 2        |
|   |        |       | 1     | Further information in extended services broadcast section 2   |
| Section 3 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 3        |
|   |        |       | 1     | Further information in extended services broadcast section 3   |
| Section 4 information sent on this cell   | 1      | M     | 0     | No information in extended services broadcast section 4        |
|   |        |       | 1     | Further information in extended services broadcast section 4   |
| NOTE: DA cells shall support extended advanced links and QoS negotiation when system wide services are supported (i.e. when the "system wide services" element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU has value 1) and shall support reception of MAC-U-BLCK PDUs. |        |       |       |  |

#### 21.4.4.2 SYNC

The SYNC PDU shall be transmitted using the BSCH and so shall be distinguishable by the synchronization burst which has a special training sequence. Its contents shall be as shown in table 21.76.

NOTE: The SYNC PDU is sent on  $\pi/4$ -DQPSK and D8PSK channels. It is always sent using  $\pi/4$ -DQPSK modulation.

The sharing mode field shall indicate whether the BS is using continuous transmission, carrier sharing, MCCH sharing or traffic carrier sharing. If MCCH sharing is indicated, the TS reserved frames field shall indicate which frames are reserved in this mode of operation. For the other values of sharing mode, the contents of the TS reserved frames field shall be ignored.

The frame 18 extension element shall indicate whether an MS is allowed to receive downlink information on all slots of the frame 18. If extension is allowed, only MSs which are capable of receiving consecutive slots are able to perform this function.

The U-plane DTX flag shall indicate whether discontinuous U-plane transmission is supported on traffic channels.

**Table 21.76: SYNC PDU contents**

| Information element | Length | Type | Value               | Remark   |

| NOTE 1: The element Colour code with the value "Predefined scrambling" means that all 30 bits of the scrambling vector are zeros.                                     |                                     |      |                     |   |
| NOTE 2: The version of the present document and ETSI EN 300 392-7 [8] may change in future enhancements of these documents without a change of the System code value. |                                     |      |                     |   |

#### 21.4.4.2a SYNC-DA

The SYNC-DA PDU shall be transmitted using the BSCH-Q and so shall be distinguishable by the frequency correction burst which is a special burst. SYNC-DA PDUs contents shall be as shown in table 21.77.

NOTE 1: A value in the downlink QAM-SLOTINFO PDU indicates the presence of the frequency correction burst in a downlink slot.

The SYNC-DA PDU shall be sent on the DA main carrier and may be sent on QAM carriers other than the DA main carrier.

NOTE 2: The BS on QAM channels do not use carrier sharing or MCCH sharing.

Table 21.77: SYNC-DA PDU contents

| Information element                                | Length | Type | Value               | Remark   |

| NOTE 2: The element Colour code with the value "Predefined scrambling" means that all 30 bits of the scrambling vector are zeros.                                     |        |      |                   |   |
| NOTE 3: This element is present only when the carrier on which the SYNC-DA PDU is sent is not the DA main carrier i.e. when element "Carrier flag" is set to 0.       |        |      |                   |   |
| NOTE 4: This element is present only when the carrier on which the SYNC-DA PDU is sent is the DA main carrier i.e. when element "Carrier flag" is set to 1.           |        |      |                   |   |
| NOTE 5: The SYNC-DA PDU is 117 bits long.   |        |      |                   |   |

#### 21.4.4.3 ACCESS-DEFINE

The ACCESS-DEFINE PDU may be sent by the BS using a half slot or full slot on the downlink (SCH/HD, SCH-P8/HD, SCH/F, SCH-P8/F or SCH-Q/D), on SCH-Q/B or on downlink STCH. It defines the random access parameters for the specified access code. Its contents shall be as shown in table 21.78.

**Table 21.78: ACCESS-DEFINE PDU contents**

| Information element                                  | Length | Type | Value             | Remark                                    |

| Subscriber class bit map   | 16     | C    |                   | as defined in clause 18                     |
| GSSI   | 24     | C    |                   | Group short subscriber identity             |
| Filler bits  | 3      | M    | 100 <sub>2</sub>  | Reserved bits to make the PDU octet bounded |
| NOTE: Values 00 <sub>2</sub> and 11 <sub>2</sub> indicate that there is no added optional field. |        |      |                   |   |

The definition of the various random access parameters is as follows:

- common or assigned flag:
  - this indicates whether the ACCESS-DEFINE PDU applies to MSs using the channel for common control or MSs using it for assigned control;
- access code:
  - this is used in the ACCESS-ASSIGN message to control access for a subdivision of the MS population;
- IMM:
  - this is the Aloha parameter defining when the MS may use the first valid access opportunity for its first random access transmission. This time is counted in terms of TDMA frames;
- WT:
  - this is the Aloha parameter defining the waiting time before the MS decides to initiate an access re-try. This time is counted in terms of BS downlink signalling opportunities for this control channel;
- Nu:
  - this is the Aloha parameter giving the number of random access transmissions an MS may send before abandoning the random access attempt;
- frame-length factor:
  - this is a multiplying factor applied to the base frame-length contained in the ACCESS-ASSIGN message;
- timeslot pointer:
  - this is a pointer to where the ACCESS-ASSIGN message shall be monitored.

## 21.4.5 TMD-SAP: MAC PDU structure for U-plane signalling

The MAC-U-SIGNAL PDU shall be used on the uplink and downlink for sending U-plane signalling information. This PDU shall only be sent using the STCH in conjunction with an established circuit mode. Its contents shall be as shown in table 21.79.

**Table 21.79: MAC-U-SIGNAL PDU contents**

| Information element          | Length | Type | Value           | Remark                      |
|------------------------------|--------|------|-----------------|-----------------------------|
| MAC PDU type                 | 2      | M    | 11 <sub>2</sub> | MAC-U-SIGNAL                |
| Second half slot stolen flag | 1      | M    | 0               | Second half slot not stolen |
|                              |        |      | 1               | Second half slot stolen     |
| TM-SDU                       | 121    | M    |                 |                             |

The first two bits of the MAC header shall distinguish this PDU as a MAC-U-SIGNAL PDU. The second half slot stolen flag shall indicate whether the second half of the full slot is also stolen. If the second half is stolen it may contain U-plane or C-plane signalling as indicated by the MAC header. The SDU contains the user information which is received from the U-plane for transmission in this PDU or passed to the U-plane on receipt of this PDU. It shall be the responsibility of the user application at the higher layer to specify the meaning of the contents of the TM-SDU. The TM-SDU length shall always be 121 bits. If the user application requires fewer bits, it is the responsibility of that application to insert filler bits to ensure a 121-bit TM-SDU length.

If MAC-U-SIGNAL is sent in the second half of a full slot, the second half slot stolen flag shall still be present but its content shall be ignored.

## 21.4.6 TMD-SAP: MAC PDU structure for U-plane traffic

The MAC-TRAFFIC PDU shall be used for sending U-plane traffic data on the uplink and downlink using TCH/S, TCH/7,2, TCH/4,8 or TCH/2,4. This PDU has no MAC header and all capacity shall be devoted to traffic information passed to and from the U-plane. When the MAC is in traffic mode, this PDU type shall be assumed unless the slot flag indicates the presence of the STCH.

When stealing does not occur, the MAC-TRAFFIC PDU shall occupy the full slot. If stealing occurs, and only the first half of the slot is stolen, the MAC-TRAFFIC PDU shall occupy the second half of the slot.

## 21.4.7 MAC PDU structure for access assignment broadcast

### 21.4.7.1 Contents of AACH-Q logical channel

The AACH-Q shall be sent by the BS on every downlink slot of a QAM channel (except slots containing BLCH-Q). The contents of the AACH-Q shall be as shown in table 21.80.

**Table 21.80: Contents of AACH-Q**

| Information element  | Length | Type | Value | Remark   |
|--|--------|------|-------|--|
| AACH-Q mode  | 1      | M    | 0     | Contents of ACCESS-ASSIGN PDU are present  |
|  |        |      | 1     | Reserved element is present  |
| Contents of ACCESS-ASSIGN PDU (see note 1)   | 14     | C    |       | This element contains the ACCESS-ASSIGN PDU, as defined in clause 21.4.7.2, tables 21.81 and 21.82 |
| Reserved (see note 2)  | 14     | C    |       | Reserved, value shall be set to all zeros  |
| NOTE 1: The contents of ACCESS-ASSIGN PDU shall be present when the AACH-Q mode element is set to 0. |        |      |       |  |
| NOTE 2: The reserved element shall be present when the AACH-Q mode element is set to 1.              |        |      |       |  |

The AACH-Q mode element indicates whether the ACCESS-ASSIGN PDU follows in the AACH-Q. The ACCESS-ASSIGN PDU is defined in clause 21.4.7.2.

In the present document, the BS should set the AACH-Q mode element to 0. However, in future editions of the present document, the BS may set the AACH-Q mode element to 1 in some downlink slots. Therefore, if the AACH-Q mode element is set to 1, the MS shall discard the following 14 bits and shall regard the ACCESS-ASSIGN PDU as not having been received in that downlink slot.

### 21.4.7.2 ACCESS-ASSIGN

The ACCESS-ASSIGN PDU is generated by the MAC and so shall not contain any TM-SDU from the layer above.

On a  $\pi/4$ -DQPSK channel, or on a D8PSK channel, the ACCESS-ASSIGN PDU shall be sent by the BS on every downlink slot. It shall use the AACH logical channel, which is mapped onto the broadcast block (see clause 9).

When sent on a QAM channel, the ACCESS-ASSIGN PDU shall use the AACH-Q logical channel. The AACH-Q shall be sent by the BS on every downlink slot of a QAM channel (except slots containing BLCH-Q). However the ACCESS-ASSIGN PDU is present in the AACH-Q only if the AACH-Q mode element is set to 0; see clause 21.4.7.1.

NOTE 1: The phase modulation Access Assignment Channel AACH contains a single PDU: the ACCESS-ASSIGN PDU.

The QAM Access Assignment Channel AACH-Q contains the 1-bit AACH-Q mode element, followed by either the ACCESS-ASSIGN PDU or a reserved element (see clause 21.4.7.1).

The ACCESS-ASSIGN PDU shall be used to convey information about the downlink slot in which it appears and also the access rights for the corresponding (same-numbered) uplink slot. Its contents shall be dependent on whether it is being sent in frames 1 to 17 or in frame 18. The contents of this PDU shall be as shown in tables 21.81 and 21.82.

**Table 21.81: ACCESS-ASSIGN PDU contents for frames 1 to 17**

| Information element  | Length | Type | Value           | Remark  |
|--|--------|------|-----------------|---|
| Header   | 2      | M    | 00 <sub>2</sub> | Downlink usage - common control<br>Uplink access rights - common only   |
|  |        |      | 01 <sub>2</sub> | Downlink usage - defined by field 1<br>Uplink access rights - common and assigned   |
|  |        |      | 10 <sub>2</sub> | Downlink usage - defined by field 1<br>Uplink access rights - assigned only   |
|  |        |      | 11 <sub>2</sub> | Downlink usage- defined by field 1<br>Uplink access rights - defined by field 2   |
| Field 1  | 6      | M    | See note        | Header 00 <sub>2</sub> : Access field 1<br>Header 01 <sub>2</sub> : Downlink usage marker<br>Header 10 <sub>2</sub> : Downlink usage marker<br>Header 11 <sub>2</sub> : Downlink usage marker |
| Field 2  | 6      | M    | See note        | Header 00 <sub>2</sub> : Access field 2<br>Header 01 <sub>2</sub> : Access field<br>Header 10 <sub>2</sub> : Access field<br>Header 11 <sub>2</sub> : Uplink usage marker                     |
| NOTE: Content and values of the fields 1 and 2 depend on the Header values as defined in the Remarks column. |        |      |                 |   |

Possible values for downlink usage marker in the field 1:

- Common and assigned control   UMr   000011<sub>2</sub>
- Common control                   UMc   000010<sub>2</sub>
- Assigned control                 UMa   000001<sub>2</sub>
- Unallocated                       UMx   000000<sub>2</sub>
- Traffic                             UMt   others (see note 2)

Possible values for uplink usage marker in the field 2:

- Unallocated  $UM_x$  000000<sub>2</sub>
- Traffic  $UM_t$  others (see note 2)

NOTE 2: The values of the  $UM_r$ ,  $UM_c$ ,  $UM_a$  and  $UM_x$  are excluded.

$UM_r$ ,  $UM_c$ ,  $UM_a$  and  $UM_x$  are pre-set usage markers which shall not be assigned as traffic usage markers.  $UM_t$  is the traffic usage marker, assigned in the MAC-RESOURCE PDU which allocated the channel.

Access field 1 shall indicate the access restrictions for the first subslot of the corresponding uplink slot. Access field 2 shall indicate the access restrictions for the second subslot of the corresponding uplink slot. Access field (with no following number) shall indicate the access restrictions for both subslots of the corresponding uplink slot. The definition of the access field contents is given in the access field element definition.

**Table 21.82: ACCESS-ASSIGN PDU contents for frame 18**

| Information element  | Length | Type | Value           | Remark  |
|--|--------|------|-----------------|---|
| Header   | 2      | M    | 00 <sub>2</sub> | Uplink access rights: common only   |
|  |        |      | 01 <sub>2</sub> | Uplink access rights: common and assigned   |
|  |        |      | 10 <sub>2</sub> | Uplink access rights: assigned only   |
|  |        |      | 11 <sub>2</sub> | Uplink access rights: common and assigned   |
| Field 1  | 6      | M    | See note        | Header 00 <sub>2</sub> : Access field 1<br>Header 01 <sub>2</sub> : Access field 1<br>Header 10 <sub>2</sub> : Access field 1<br>Header 11 <sub>2</sub> : Traffic usage marker ( $UM_t$ ) |
| Field 2  | 6      | M    | See note        | Header 00 <sub>2</sub> : Access field 2<br>Header 01 <sub>2</sub> : Access field 2<br>Header 10 <sub>2</sub> : Access field 2<br>Header 11 <sub>2</sub> : Access field                    |
| NOTE: Content and values of the fields 1 and 2 depend on the Header values as defined in the Remarks column. |        |      |                 |   |

## 21.4.8 MAC PDU structure for slot information channel

### 21.4.8.1 QAM-SLOTINFO (uplink)

This PDU is generated by the MAC and so shall not contain any TM-SDU from the layer above. This PDU shall be sent by the MS, within the SICH-Q/U, whenever it transmits a QAM slot or subslot by reserved access.

NOTE: The QAM Uplink Slot Information Channel SICH-Q/U contains a single PDU: the uplink QAM-SLOTINFO PDU.

This PDU indicates the format of the remainder of the uplink slot or subslot in which it appears. Its contents shall be as shown in table 21.83.

**Table 21.83: QAM-SLOTINFO (uplink) PDU contents**

| Information element | Length | Type | Value              | Remark            |
|---------------------|--------|------|--------------------|-------------------|
| Slot format         | 5      | M    | 00000 <sub>2</sub> | 4-QAM rate = 1/2  |
|                     |        |      | 00001 <sub>2</sub> | 16-QAM rate = 1/2 |
|                     |        |      | 00010 <sub>2</sub> | 16-QAM rate = 1   |
|                     |        |      | 00011 <sub>2</sub> | 64-QAM rate = 1/2 |
|                     |        |      | 00100 <sub>2</sub> | 64-QAM rate = 2/3 |
|                     |        |      | 00101 <sub>2</sub> | 64-QAM rate = 1   |
|                     |        |      | 00110 <sub>2</sub> | Reserved          |
|                     |        |      | etc.               | etc.              |
|                     |        |      | 11111 <sub>2</sub> | Reserved          |

### 21.4.8.2 QAM-SLOTINFO (downlink)

This PDU is generated by the MAC and so shall not contain any TM-SDU from the layer above. It shall be sent by the BS, within the SICH-Q/D, in every downlink slot on a QAM channel except slots containing BLCH-Q.

NOTE: The QAM Downlink Slot Information Channel SICH-Q/D contains a single PDU: the downlink QAM-SLOTINFO PDU.

This PDU indicates the format of the remainder of the downlink slot in which it appears (except the AACH-Q which always uses 4-QAM rate = 1/2). Its contents shall be as shown in table 21.84.

**Table 21.84: QAM-SLOTINFO (downlink) PDU contents**

| Information element | Length | Type | Value              | Remark  |
|---------------------|--------|------|--------------------|---|
| Slot format         | 5      | M    | 00000 <sub>2</sub> | 4-QAM rate = 1/2  |
|                     |        |      | 00001 <sub>2</sub> | 16-QAM rate = 1/2   |
|                     |        |      | 00010 <sub>2</sub> | 16-QAM rate = 1   |
|                     |        |      | 00011 <sub>2</sub> | 64-QAM rate = 1/2   |
|                     |        |      | 00100 <sub>2</sub> | 64-QAM rate = 2/3   |
|                     |        |      | 00101 <sub>2</sub> | 64-QAM rate = 1   |
|                     |        |      | 00110 <sub>2</sub> | Reserved  |
|                     |        |      | etc.               | etc.  |
|                     |        |      | 01110 <sub>2</sub> | Reserved  |
|                     |        |      | 01111 <sub>2</sub> | Frequency correction burst (FCB) (which contains SYNC-DA PDU) |
|                     |        |      | 10000 <sub>2</sub> | Reserved  |
|                     |        |      | etc.               | etc.  |
|                     |        |      | 11111 <sub>2</sub> | Reserved  |

## 21.5 MAC elements

### 21.5.0 General

Clauses 21.5.1 to 21.5.7 describe the information elements which are referred to in the MAC PDU descriptions. The contents of those information elements shall as defined in tables 21.85 to 21.96.

### 21.5.1 Access field

**Table 21.85: Access field information element contents**

| Information element  | Length      | Type | Value             | Remark                              |
|--|-------------|------|-------------------|-------------------------------------|
| Access code  | 2           | M    | 00 <sub>2</sub>   | Access code A                       |
|  |             |      | 01 <sub>2</sub>   | Access code B                       |
|  |             |      | 10 <sub>2</sub>   | Access code C                       |
|  |             |      | 11 <sub>2</sub>   | Access code D                       |
| Base frame-length  | 4           | M    | 0000 <sub>2</sub> | Reserved subslot, see note 1        |
|  |             |      | 0001 <sub>2</sub> | CLCH(-Q) subslot, see notes 1 and 2 |
|  |             |      | 0010 <sub>2</sub> | Ongoing frame                       |
|  |             |      | 0011 <sub>2</sub> | 1 subslot                           |
|  |             |      | 0100 <sub>2</sub> | 2 subslots                          |
|  |             |      | 0101 <sub>2</sub> | 3 subslots                          |
|  |             |      | 0110 <sub>2</sub> | 4 subslots                          |
|  |             |      | 0111 <sub>2</sub> | 5 subslots                          |
|  |             |      | 1000 <sub>2</sub> | 6 subslots                          |
|  |             |      | 1001 <sub>2</sub> | 8 subslots                          |
|  |             |      | 1010 <sub>2</sub> | 10 subslots                         |
|  |             |      | 1011 <sub>2</sub> | 12 subslots                         |
|  |             |      | 1100 <sub>2</sub> | 16 subslots                         |
|  |             |      | 1101 <sub>2</sub> | 20 subslots                         |
| 1110 <sub>2</sub>  | 24 subslots |      |                   |                                     |
| 1111 <sub>2</sub>  | 32 subslots |      |                   |                                     |
| NOTE 1: For these values access code has no meaning.   |             |      |                   |                                     |
| NOTE 2: CLCH and CLCH-Q are permitted only in subslot 1 as specified in clauses 9.5.1, 9.5.1a and 9.5.6. |             |      |                   |                                     |

## 21.5.2 Channel allocation

Table 21.86: Channel allocation information element contents

| Information element  | Length | Type | Value             | Remark  |
|--|--------|------|-------------------|---|
| Allocation type  | 2      | M    | 00 <sub>2</sub>   | Replace current channel with specified channel  |
|  |        |      | 01 <sub>2</sub>   | Additional channel allocation   |
|  |        |      | 10 <sub>2</sub>   | Quit current channel and go to specified channel  |
|  |        |      | 11 <sub>2</sub>   | Replace current channel with specified channel plus carrier specific signalling channel in slot 1 |
| Timeslot assigned  | 4      | M    | 0000 <sub>2</sub> | Go to appropriate common control channel (MCCH, MCCH-Q or common SCCH)                            |
|  |        |      | 0001 <sub>2</sub> | Timeslot number 4   |
|  |        |      | 0010 <sub>2</sub> | Timeslot bit map  |
|  |        |      | etc.              | etc.  |
|  |        |      | 1110 <sub>2</sub> | Timeslot bit map  |
|  |        |      | 1111 <sub>2</sub> | All four timeslots  |
| Up/downlink assigned   | 2      | M    | 00 <sub>2</sub>   | Augmented channel allocation (see note 1)   |
|  |        |      | 01 <sub>2</sub>   | Downlink only   |
|  |        |      | 10 <sub>2</sub>   | Uplink only   |
|  |        |      | 11 <sub>2</sub>   | Both uplink and downlink  |
| CLCH(-Q) permission  | 1      | M    | 0                 | No immediate CLCH(-Q) permission  |
|  |        |      | 1                 | Immediate CLCH(-Q) permission   |
| Cell change flag   | 1      | M    | 0                 | No cell change  |
|  |        |      | 1                 | Cell change   |
| Carrier number   | 12     | M    |                   | Carrier frequency number  |
| Extended carrier numbering flag                                    | 1      | M    | 0                 | No extended carrier numbering   |
|  |        |      | 1                 | Extended carrier numbering  |
| Frequency band (see note 2)  | 4      | C    |                   | Provision for different frequency bands   |
| Offset (see note 2)  | 2      | C    | 00 <sub>2</sub>   | 0 kHz offset  |
|  |        |      | 01 <sub>2</sub>   | +6,25 kHz offset  |
|  |        |      | 10 <sub>2</sub>   | -6,25 kHz offset  |
|  |        |      | 11 <sub>2</sub>   | +12,5 kHz offset  |
| Duplex spacing (see note 2)  | 3      | C    |                   | Provision for different duplex spacing  |
| Reverse operation (see note 2)                                     | 1      | C    | 0                 | Normal  |
|  |        |      | 1                 | Reverse   |
| Monitoring pattern (see clause 9)                                  | 2      | M    | 00 <sub>2</sub>   | No monitoring pattern   |
|  |        |      | 01 <sub>2</sub>   | One monitoring pattern  |
|  |        |      | 10 <sub>2</sub>   | Two monitoring patterns   |
|  |        |      | 11 <sub>2</sub>   | Three monitoring patterns   |
| Frame 18 monitoring pattern (see note 3)                           | 2      | C    | 00 <sub>2</sub>   | No monitoring pattern   |
|  |        |      | 01 <sub>2</sub>   | One monitoring pattern  |
|  |        |      | 10 <sub>2</sub>   | Two monitoring patterns   |
|  |        |      | 11 <sub>2</sub>   | Three monitoring patterns   |
| Up/downlink assigned for augmented channel allocation (see note 4) | 2      | C    | 00 <sub>2</sub>   | Reserved (see note 5)   |
|  |        |      | 01 <sub>2</sub>   | Downlink only   |
|  |        |      | 10 <sub>2</sub>   | Uplink only   |
|  |        |      | 11 <sub>2</sub>   | Both uplink and downlink  |
| Bandwidth of allocated channel (see notes 4 and 6)                 | 3      | C    | 000 <sub>2</sub>  | 25 kHz  |
|  |        |      | 001 <sub>2</sub>  | 50 kHz  |
|  |        |      | 010 <sub>2</sub>  | 100 kHz   |
|  |        |      | 011 <sub>2</sub>  | 150 kHz   |
|  |        |      | 100 <sub>2</sub>  | Reserved  |
|  |        |      | etc.              | etc.  |
|  |        |      | 111 <sub>2</sub>  | Reserved  |

| Information element                                     | Length   | Type | Value            | Remark  |

|   |          |      | 1                | Conditional element B present   |
| Conditional element B (see notes 12 and 14)             | 16       | C    |                  | Reserved  |
| Further augmentation flag (see note 4)                  | 1        | C    | 0                | No further augmentation of channel allocation                                   |
|   |          |      | 1                | Further augmentation of channel allocation (see note 15)                        |

| Information element | Length | Type | Value | Remark   |
|---------------------|--------|------|-------|--|
| NOTE 1:             |        |      |       | If an MS that does not support augmented channel allocations receives a channel allocation with the up/downlink assigned element set to 00 <sub>2</sub> , it shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation.     |
| NOTE 2:             |        |      |       | This element shall be present only in the case of extended carrier numbering i.e. extended carrier numbering flag set to 1.  |
| NOTE 3:             |        |      |       | This element shall be present only in the case that no monitoring pattern is assigned i.e. monitoring pattern element set to 00 <sub>2</sub> .   |
| NOTE 4:             |        |      |       | This element shall be present only for an augmented channel allocation i.e. up/downlink assigned element set to 00 <sub>2</sub> .  |
| NOTE 5:             |        |      |       | If the MS receives a channel allocation with the up/downlink assigned for augmented channel allocation element set to 00 <sub>2</sub> , it shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation.                       |
| NOTE 6:             |        |      |       | This element shall be set to 000 <sub>2</sub> when allocating a $\pi/4$ -DQPSK channel or a D8PSK channel.   |
| NOTE 7:             |        |      |       | This element shall be present only for an augmented channel allocation allocating a QAM channel i.e. up/downlink assigned element set to 00 <sub>2</sub> and modulation mode of allocated channel element set to 010 <sub>2</sub> .  |
| NOTE 8:             |        |      |       | If the MS does not understand the value of this element, it shall regard the value as indicating the maximum QAM modulation level supported by that MS.  |
| NOTE 9:             |        |      |       | This element shall be present only for an augmented channel allocation not allocating a QAM channel i.e. up/downlink assigned element set to 00 <sub>2</sub> and modulation mode of allocated channel element not set to 010 <sub>2</sub> .  |
| NOTE 10:            |        |      |       | This element shall be present only for an augmented channel allocation with napping information included i.e. up/downlink assigned element set to 00 <sub>2</sub> and napping status element set to 01 <sub>2</sub> .  |
| NOTE 11:            |        |      |       | This element shall be present only for an augmented channel allocation with the Conditional element A flag indicating that the Conditional element A is present i.e. up/downlink assigned element set to 00 <sub>2</sub> and Conditional element A flag set to 1.                                      |
| NOTE 12:            |        |      |       | This element shall be present only for an augmented channel allocation with the Conditional element B flag indicating that the Conditional element B is present i.e. up/downlink assigned element set to 00 <sub>2</sub> and Conditional element B flag set to 1.                                      |
| NOTE 13:            |        |      |       | The Conditional element B flag shall be set to 0 in the present document.  |
| NOTE 14:            |        |      |       | Conditional element B shall not be included in the present document. However, if the MS receives a channel allocation with the Conditional element B flag set to 1, it shall assume that a 16-bit element is included following the Conditional element B flag.  |
| NOTE 15:            |        |      |       | The further augmentation flag shall be set to 0 in the present document. If the MS receives a channel allocation with the further augmentation flag set to 1, it shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation. |

When commanded to an assigned channel by channel allocation the MS moves to the assigned channel and back to the common control channel according to the received channel allocations as described in clause 23.5.4.

NOTE 1: If the number of  $\pi/4$ -DQPSK common SCCHs is changed while a CA MS has been on an assigned channel, the change is indicated in the SYSINFO PDU (and in SYSINFO-Q PDU, if applicable); see clause 23.3.1.2.1.2.

NOTE 2: If the MCCH-Q width (in slots) or the number of QAM common SCCHs is changed while a DA MS has been on an assigned channel, the change is indicated in the SYSINFO-DA PDU; see clause 23.3.1.2.1.3.

The CLCH(-Q) permission field shall indicate to the MS whether the first sub-slot on the allocated channel shall be available for linearization purposes: CLCH on a  $\pi/4$ -DQPSK or D8PSK channel, or CLCH-Q on a QAM channel. The MS need not examine the ACCESS-ASSIGN PDU in the AACH or AACH-Q in order to use CLCH or CLCH-Q if permission is given in the channel allocation field.

The carrier frequency shall be defined by the following elements:

- carrier number;
- extended carrier numbering flag;
- frequency band;
- offset;
- duplex spacing;

- reverse operation;
- bandwidth of allocated channel.

The extended numbering flag indicates whether the carrier frequency specification includes the frequency band, offset, duplex spacing and reverse operation fields. If this field indicates no extended numbering, then the MS shall assume the same frequency band, offset, duplex spacing and reverse operation values as contained in the SYSINFO or SYSINFO-Q PDU (for a CA MS) or SYSINFO-DA PDU (for a DA MS); this refers to the SYSINFO, SYSINFO-Q or SYSINFO-DA PDU received on the current cell (i.e. the cell on which the channel allocation was received), even when the cell change flag indicates a cell change. If the bandwidth of allocated channel field is not included, then the MS shall assume that the bandwidth is 25 kHz. The actual carrier frequency shall then be calculated using a similar method to that defined for the main carrier frequency calculation. The carrier frequency shall be as defined by the following equations:

$$\begin{aligned} \text{downlink carrier frequency} &= \text{base frequency} + (\text{carrier number} \times 25 \text{ kHz}) + \text{offset kHz} \\ &+ ((\text{bandwidth of allocated channel} / 2) - 12,5) \text{ kHz} \end{aligned}$$

- normal operation:

$$\text{uplink carrier frequency} = \text{downlink carrier frequency} - \text{duplex spacing}$$

- reverse operation:

$$\text{uplink carrier frequency} = \text{downlink carrier frequency} + \text{duplex spacing.}$$

The mappings of the frequency band field values to actual base frequencies and the duplex spacing field values to actual duplex frequency spacing are defined in ETSI TS 100 392-15 [18].

NOTE 3: For bandwidths greater than 25 kHz, the carrier number refers to the centre frequency of the lowest 25 kHz comprising the allocated channel. The final term (relating to the bandwidth) in the equation for the downlink carrier frequency then generates the centre frequency of the allocated channel.

NOTE 4: If there are MSs from different cells sharing an assigned channel and the BS sends a channel allocation on the channel, particularly to a group of MSs from different cells, the BS includes the extended carrier numbering if there are any differences of frequency band, offset, duplex spacing or reverse operation between the main carriers of the sharing cells.

The monitoring pattern field applies to a transmitting MS on an assigned channel and it indicates which downlink slots shall be monitored while transmitting traffic. If one monitoring pattern is assigned, monitoring pattern number one as defined in clause 9 shall be used. If two monitoring patterns are assigned, monitoring pattern numbers one and two as defined in clause 9 shall be used. If three monitoring patterns are assigned, monitoring pattern numbers one, two and three as defined in clause 9 shall be used.

If no monitoring pattern is assigned, then the frame 18 monitoring pattern field shall be included to indicate which monitoring patterns shall be followed for frame 18. One, two or three monitoring patterns can be assigned for frame 18 in the same way as described before. So, for example, if one monitoring pattern is assigned, the MS shall monitor frame 18 if Multiframe Number mod 3 = 0; if two monitoring patterns are assigned, the MS shall monitor frame 18 if Multiframe Number mod 3 = 0 or 2.

Values 01<sub>2</sub>, 10<sub>2</sub>, and 11<sub>2</sub> in the up/downlink assigned field indicate whether either or both directions on the allocated channel have been assigned exclusively for the usage required by the MS. Value 00<sub>2</sub> in the up/downlink assigned field indicates that this is an augmented channel allocation. In this case the following conditional fields shall be included:

- up/downlink assigned for augmented channel allocation;
- bandwidth of the allocated channel;
- modulation mode of the allocated channel;
- the maximum uplink QAM modulation level, or a 3-bit reserved element;
- conforming channel status of the allocated channel;
- BS link imbalance on the allocated channel (see clause 21.5.2a);

- BS transmit power on the allocated channel relative to the main carrier (see clause 21.5.2b);
- napping status on the allocated channel and, optionally, napping information (see clause 21.5.2c);
- a 4-bit reserved element;
- a flag indicating whether a 16-bit conditional element A is present, and the conditional element A if appropriate;
- a flag indicating whether a 16-bit conditional element B is present, and the conditional element B if appropriate; and
- a flag indicating further augmentation of the channel allocation (allowing for future further extension).

If the channel allocation is not augmented:

- a CA MS shall assume that the allocated channel is a 25 kHz  $\pi/4$ -DQPSK conforming channel, that the BS transmit power on the allocated channel relative to the CA main carrier is 0 dB and that use of the napping procedure is not permitted on the allocated channel;
- if element "timeslot assigned"  $\neq$  0000<sub>2</sub>, a DA MS shall assume that the allocated channel is a 25 kHz  $\pi/4$ -DQPSK conforming channel, that the BS transmit power on the allocated channel relative to the DA main carrier is 0 dB and that use of the napping procedure is not permitted on the allocated channel;
- if element "timeslot assigned" = 0000<sub>2</sub>, a DA MS shall make the assumptions specified in clause 23.5.4.3.2 (i.e. using the information about the DA main carrier from the last received SYSINFO-DA or SYNC-DA PDU).

## 21.5.2a BS link imbalance

**Table 21.87: "BS link imbalance" information element contents**

| Information element | Length   | Type | Value             | Remark         |
|---------------------|----------|------|-------------------|----------------|
| BS link imbalance   | 4        | M    | 0000 <sub>2</sub> | No information |
|                     |          |      | 0001 <sub>2</sub> | Reserved       |
|                     |          |      | 0010 <sub>2</sub> | Reserved       |
|                     |          |      | 0011 <sub>2</sub> | -12,5 dB       |
|                     |          |      | 0100 <sub>2</sub> | -10 dB         |
|                     |          |      | 0101 <sub>2</sub> | -7,5 dB        |
|                     |          |      | 0110 <sub>2</sub> | -5 dB          |
|                     |          |      | 0111 <sub>2</sub> | -2,5 dB        |
|                     |          |      | 1000 <sub>2</sub> | 0 dB           |
|                     |          |      | 1001 <sub>2</sub> | 2,5 dB         |
|                     |          |      | 1010 <sub>2</sub> | 5 dB           |
|                     |          |      | 1011 <sub>2</sub> | 7,5 dB         |
|                     |          |      | 1100 <sub>2</sub> | 10 dB          |
|                     |          |      | 1101 <sub>2</sub> | 12,5 dB        |
|                     |          |      | 1110 <sub>2</sub> | Reserved       |
| 1111 <sub>2</sub>   | Reserved |      |                   |                |

The BS shall set the "BS link imbalance" information element to:

$$\begin{aligned}
 & ( \text{BS transmit power} - \text{MS\_TXPWR\_MAX\_CELL} ) \\
 & + \text{Gain in the BS transmitter feeder and antenna} \\
 & - \text{Gain in the BS receiver feeder and antenna} \\
 & + ( \text{BS static receive sensitivity} - \text{MS static reference sensitivity} ),
 \end{aligned}$$

where all parameters are those applicable to the channel and the receive sensitivities are for the lowest modulation level supported by the channel (i.e.  $\pi/4$ -DQPSK or 4-QAM).

The MS may use the BS link imbalance, together with an MS correction factor (see note 1), to estimate the uplink performance from measurements of the downlink channel; this information may be a criterion in the MS's link adaptation procedures for choice of the current appropriate bit rate on a D8PSK or QAM channel; see clause 23.4.9.

NOTE 1: The MS correction factor should allow for the MS's actual transmit power, its actual static sensitivity and any receive/transmit imbalance in the performance of its antenna. For example, the MS might choose to use the following or equivalent correction factor:

$$\begin{aligned} & ( \text{MS\_TXPWR\_MAX\_CELL} - \text{MS actual transmit power} ) \\ & - \text{Gain in the MS transmitter feeder and antenna} \\ & + \text{Gain in the MS receiver feeder and antenna} \\ & + ( \text{MS static reference sensitivity} - \text{MS actual static sensitivity} ). \end{aligned}$$

NOTE 2: In the above expressions for the BS link imbalance and the MS correction factor, the "gain in the receiver feeder and antenna" is assumed to include any diversity gain.

## 21.5.2b BS transmit power relative to main carrier

**Table 21.88: "BS transmit power relative to main carrier" information element contents**

| Information element                        | Length | Type | Value              | Remark             |
|--|--------|------|--------------------|--------------------|
| BS transmit power relative to main carrier | 5      | M    | 00000 <sub>2</sub> | Reserved           |
|  |        |      | etc.               | etc.               |
|  |        |      | 00100 <sub>2</sub> | Reserved           |
|  |        |      | 00101 <sub>2</sub> | -22 dB             |
|  |        |      | 00110 <sub>2</sub> | -20 dB             |
|  |        |      | etc.               | etc. in 2 db steps |
|  |        |      | 10000 <sub>2</sub> | 0 dB               |
|  |        |      | etc.               | etc. in 2 dB steps |
|  |        |      | 11010 <sub>2</sub> | 20 dB              |
|  |        |      | 11011 <sub>2</sub> | 22 dB              |
|  |        |      | 11100 <sub>2</sub> | Reserved           |
|  |        |      | etc.               | etc.               |
|  |        |      | 11111 <sub>2</sub> | Reserved           |

The value of the BS transmit power relative to main carrier element shall include the BS relative antenna gains; i.e. it is the BS Effective Radiated Power (ERP) into the allocated channel relative to the BS ERP of the main carrier.

## 21.5.2c Napping information

Table 21.89: "Napping information" information element contents

| Information element                | Length | Type | Value             | Remark   |
|------------------------------------|--------|------|-------------------|--|
| Napping reception timeslots        | 4      | M    | 0000 <sub>2</sub> | Reserved   |
|                                    |        |      | 0001 <sub>2</sub> | Timeslot number 4  |
|                                    |        |      | 0010 <sub>2</sub> | Timeslot bit map   |
|                                    |        |      | etc.              | etc.   |
|                                    |        |      | 1110 <sub>2</sub> | Timeslot bit map   |
|                                    |        |      | 1111 <sub>2</sub> | All four timeslots   |
| Napping reception frames           | 3      | M    | 000 <sub>2</sub>  | All TDMA frames  |
|                                    |        |      | 001 <sub>2</sub>  | Odd-numbered TDMA frames<br>i.e. frames 1, 3, 5, 7, 9, 11, 13, 15 and 17   |
|                                    |        |      | 010 <sub>2</sub>  | Even-numbered TDMA frames<br>i.e. frames 2, 4, 6, 8, 10, 12, 14, 16 and 18 |
|                                    |        |      | 011 <sub>2</sub>  | Frames 1, 4, 7, 10, 13 and 16  |
|                                    |        |      | 100 <sub>2</sub>  | Frames 2, 5, 8, 11, 14 and 17  |
|                                    |        |      | 101 <sub>2</sub>  | Frames 3, 6, 9, 12, 15 and 18  |
|                                    |        |      | 110 <sub>2</sub>  | Reserved   |
|                                    |        |      | 111 <sub>2</sub>  | Reserved   |
| Napping timer T.226                | 3      | M    | 000 <sub>2</sub>  | 6 TDMA frames  |
|                                    |        |      | 001 <sub>2</sub>  | 9 TDMA frames  |
|                                    |        |      | 010 <sub>2</sub>  | 12 TDMA frames   |
|                                    |        |      | 011 <sub>2</sub>  | 18 TDMA frames   |
|                                    |        |      | 100 <sub>2</sub>  | 27 TDMA frames   |

## 21.5.2d Conditional element A

Table 21.90: Conditional element A information element contents

| Information element                           | Length   | Type | Value              | Remark  |
|---|----------|------|--------------------|---|
| DA conforming channel status                  | 3        | M    | 000 <sub>2</sub>   | Conforming channel (therefore concentric)             |
|   |          |      | 001 <sub>2</sub>   | Non-conforming channel: concentric                    |
|   |          |      | 010 <sub>2</sub>   | Non-conforming channel: sectored                      |
|   |          |      | 011 <sub>2</sub>   | Non-conforming channel: super-sectored                |
|   |          |      | 100 <sub>2</sub>   | Non-conforming channel: eccentric                     |
|   |          |      | 101 <sub>2</sub>   | Reserved  |
|   |          |      | etc.               | etc.  |
|   |          |      | 111 <sub>2</sub>   | Reserved  |
| BS transmit power relative to current carrier | 5        | M    | 00000 <sub>2</sub> | Reserved  |
|   |          |      | etc.               | etc.  |
|   |          |      | 00100 <sub>2</sub> | Reserved  |
|   |          |      | 00101 <sub>2</sub> | -22 dB  |
|   |          |      | 00110 <sub>2</sub> | -20 dB  |
|   |          |      | etc.               | etc. in 2 dB steps                                    |
|   |          |      | 10000 <sub>2</sub> | 0 dB  |
|   |          |      | etc.               | etc. in 2 dB steps                                    |
|   |          |      | 11010 <sub>2</sub> | 20 dB   |
|   |          |      | 11011 <sub>2</sub> | 22 dB   |
|   |          |      | 11100 <sub>2</sub> | Reserved  |
|   |          |      | etc.               | etc.  |
| 11111 <sub>2</sub>                            | Reserved |      |                    |   |
| Reserved                                      | 8        | M    |                    | Reserved, value shall be set to 00000000 <sub>2</sub> |

The value of the BS transmit power relative to the current carrier element shall include the BS relative antenna gains; i.e. it is the BS Effective Radiated Power (ERP) into the allocated channel relative to the BS ERP of the current carrier.

## 21.5.3 Power control

Table 21.91: Power control information element contents

| Information element   | Length               | Type | Value             | Remark                               |
|---|----------------------|------|-------------------|--------------------------------------|
| Power control   | 4                    | M    | 0000 <sub>2</sub> | No change in power                   |
|   |                      |      | 0001 <sub>2</sub> | Increase power by 1 step             |
|   |                      |      | 0010 <sub>2</sub> | Increase power by 2 steps            |
|   |                      |      | 0011 <sub>2</sub> | Increase power by 3 steps            |
|   |                      |      | 0100 <sub>2</sub> | Increase power by 4 steps            |
|   |                      |      | 0101 <sub>2</sub> | Increase power by 5 steps            |
|   |                      |      | 0110 <sub>2</sub> | Increase power by 6 steps (see note) |
|   |                      |      | 0111 <sub>2</sub> | Maximum path delay exceeded          |
|   |                      |      | 1000 <sub>2</sub> | Revert to open loop power control    |
|   |                      |      | 1001 <sub>2</sub> | Decrease power by 1 step             |
|   |                      |      | 1010 <sub>2</sub> | Decrease power by 2 steps            |
|   |                      |      | 1011 <sub>2</sub> | Decrease power by 3 steps            |
|   |                      |      | 1100 <sub>2</sub> | Decrease power by 4 steps            |
|   |                      |      | 1101 <sub>2</sub> | Decrease power by 5 steps            |
|   |                      |      | 1110 <sub>2</sub> | Decrease power by 6 steps            |
| 1111 <sub>2</sub>   | Radio uplink failure |      |                   |                                      |
| NOTE: The value 0110 <sub>2</sub> may have a different meaning when sent to an air MS (see clause O.7.1.4). |                      |      |                   |                                      |

The power control step size is nominally 5 dB as defined in clause 6 except for power classes nL, where n is 1 to 4 (refer to the nominal power of MS transmitters defined in clause 6.4.1.2). For those power classes the step between the nominal power and the first lower power level is 2,5 db so that the nominal MS power control levels defined in clause 6.4.1.2 are applicable except for the highest power. The power shall not be decreased below the minimum power control level of 15 dBm or increased above the nominal power of that MS class.

## 21.5.4 Reservation requirement

**Table 21.92: Reservation requirement information element contents in MAC-ACCESS, MAC-END-HU, MAC-DATA and uplink MAC-END PDUs**

| Information element     | Length                      | Type | Value             | Remark             |
|-------------------------|-----------------------------|------|-------------------|--------------------|
| Reservation requirement | 4                           | M    | 0000 <sub>2</sub> | 1 subslot required |
|                         |                             |      | 0001 <sub>2</sub> | 1 slot required    |
|                         |                             |      | 0010 <sub>2</sub> | 2 slots required   |
|                         |                             |      | 0011 <sub>2</sub> | 3 slots required   |
|                         |                             |      | 0100 <sub>2</sub> | 4 slots required   |
|                         |                             |      | 0101 <sub>2</sub> | 5 slots required   |
|                         |                             |      | 0110 <sub>2</sub> | 6 slots required   |
|                         |                             |      | 0111 <sub>2</sub> | 8 slots required   |
|                         |                             |      | 1000 <sub>2</sub> | 10 slots required  |
|                         |                             |      | 1001 <sub>2</sub> | 13 slots required  |
|                         |                             |      | 1010 <sub>2</sub> | 17 slots required  |
|                         |                             |      | 1011 <sub>2</sub> | 24 slots required  |
|                         |                             |      | 1100 <sub>2</sub> | 34 slots required  |
|                         |                             |      | 1101 <sub>2</sub> | 51 slots required  |
| 1110 <sub>2</sub>       | 68 slots required           |      |                   |                    |
| 1111 <sub>2</sub>       | More than 68 slots required |      |                   |                    |

**Table 21.93: Reservation requirement information element contents in MAC-U-BLCK PDU**

| Information element     | Length                     | Type | Value             | Remark             |
|-------------------------|----------------------------|------|-------------------|--------------------|
| Reservation requirement | 4                          | M    | 0000 <sub>2</sub> | 1 subslot required |

|                     |        |      | 1     | Common frame                     |
| Reserved            | 1      | M    | 0     | Default value                    |
|                     |        |      | 1     | Not used in the present document |
| Reserved            | 1      | M    | 0     | Default value                    |
|                     |        |      | 1     | Not used in the present document |

## 21.5.6 Basic slot granting

Table 21.95: Basic slot granting information element contents

| Information element  | Length | Type | Value             | Remark   |
|--|--------|------|-------------------|--|
| Capacity Allocation  | 4      | M    | 0000 <sub>2</sub> | First subslot allocated                              |
|  |        |      | 0001 <sub>2</sub> | 1 slot allocated                                     |
|  |        |      | 0010 <sub>2</sub> | 2 slots allocated                                    |
|  |        |      | 0011 <sub>2</sub> | 3 slots allocated                                    |
|  |        |      | 0100 <sub>2</sub> | 4 slots allocated                                    |
|  |        |      | 0101 <sub>2</sub> | 5 slots allocated                                    |
|  |        |      | 0110 <sub>2</sub> | 6 slots allocated                                    |
|  |        |      | 0111 <sub>2</sub> | 8 slots allocated                                    |
|  |        |      | 1000 <sub>2</sub> | 10 slots allocated                                   |
|  |        |      | 1001 <sub>2</sub> | 13 slots allocated                                   |
|  |        |      | 1010 <sub>2</sub> | 17 slots allocated                                   |
|  |        |      | 1011 <sub>2</sub> | 24 slots allocated                                   |
|  |        |      | 1100 <sub>2</sub> | 34 slots allocated                                   |
|  |        |      | 1101 <sub>2</sub> | 51 slots allocated                                   |
|  |        |      | 1110 <sub>2</sub> | 68 slots allocated                                   |
| Granting delay (see note)  | 4      | M    | 0000 <sub>2</sub> | Capacity allocation at next opportunity              |
|  |        |      | 0001 <sub>2</sub> | Number of opportunities delay to capacity allocation |
|  |        |      | etc.              | etc.   |
|  |        |      | 1101 <sub>2</sub> | Number of opportunities delay to capacity allocation |
|  |        |      | 1110 <sub>2</sub> | Allocation starts at first opportunity in frame 18   |
|  |        |      | 1111 <sub>2</sub> | Wait for another slot granting message               |
| NOTE: For basic slot granting, and for the first basic slot granting element in a multiple slot grant, the granting delay is counted from the slot containing the slot grant. For multiple slot granting, the granting delay in the second and subsequent basic slot granting elements (either explicitly included or implicit) is counted from the end of the grant defined by the previous basic slot granting element (either explicitly included or implicit). |        |      |                   |  |

## 21.5.7 Multiple slot granting

**Table 21.96: Multiple slot granting information element contents**

| Information element   | Length                | Type | Value             | Remark   |
|---|-----------------------|------|-------------------|--|
| Number of slot granting sets<br>(see note 1)  | 3                     | M    | 000 <sub>2</sub>  | Reserved (see note 2)                                  |
|   |                       |      | 001 <sub>2</sub>  | 1 slot granting set                                    |
|   |                       |      | etc.              | etc.   |
|   |                       |      | 111 <sub>2</sub>  | 7 slot granting sets                                   |
| Basic slot granting element<br>(see note 3)   | 8                     | C    |                   | See basic slot granting information element definition |
| Implicit repeat count<br>(see note 3)   | 4                     | C    | 0000 <sub>2</sub> | No implicit repetition of basic slot granting element  |
|   |                       |      | 0001 <sub>2</sub> | 1 implicit repetition of basic slot granting element   |
|   |                       |      | etc.              | etc.   |
|   |                       |      | 1010 <sub>2</sub> | 10 implicit repetitions of basic slot granting element |
|   |                       |      | 1011 <sub>2</sub> | Reserved (see note 4)                                  |
|   |                       |      | 1100 <sub>2</sub> | Reserved (see note 4)                                  |
|   |                       |      | 1101 <sub>2</sub> | Reserved (see note 4)                                  |
|   |                       |      | 1110 <sub>2</sub> | Reserved (see note 4)                                  |
| 1111 <sub>2</sub>   | Reserved (see note 4) |      |                   |  |
| <p>NOTE 1: The "number of slot granting sets" element indicates the number of slot granting sets that follow in the PDU. Each slot granting set comprises two information elements i.e. "basic slot granting element" and "implicit repeat count". The information elements in each repeated set shall be in the order specified. For example, if the "number of slot granting sets" element is set to 010<sub>2</sub>, it is followed by: first basic slot granting element, implicit repeat count for first basic slot granting element, second basic slot granting element, implicit repeat count for second basic slot granting element.</p> <p>NOTE 2: If the MS receives a value of 000<sub>2</sub> in the "number of slot granting sets" element, it shall discard the "multiple slot granting" element and the remainder of the MAC-RESOURCE or MAC-END PDU that contains this "multiple slot granting" element.</p> <p>NOTE 3: Shall be repeated as a set as indicated by the "number of slot granting sets" element.</p> <p>NOTE 4: Reserved for future use. An MS receiving one of these values from a BS shall discard this slot granting set and any subsequent slot granting sets within the same "multiple slot granting" element.</p> |                       |      |                   |  |

## 21.6 Units used in length indication

The "length indication" element in some TMA-SAP MAC PDUs indicates the length of the MAC PDU in units of:

- $Y_1$  and  $Z_1$  octets, for a PDU sent in a subslot (i.e. MAC-ACCESS or MAC-END-HU); and
- $Y_2$  and  $Z_2$  octets, for a PDU sent in a slot (i.e. MAC-DATA, MAC-RESOURCE or MAC-END);

where the values of  $Y_1$ ,  $Z_1$ ,  $Y_2$  and  $Z_2$  depend on the bandwidth, modulation and coding rate with which the PDU is sent. The values of  $Y_1$ ,  $Z_1$ ,  $Y_2$  and  $Z_2$  are given in table 21.97 for each combination.

Table 21.97: Value of  $Y_1$ ,  $Z_1$ ,  $Y_2$  and  $Z_2$  in TMA-SAP MAC PDUs

| Modulation and QAM coding rate and bandwidth with which PDU is sent | $Y_1$<br>(PDU sent in a subslot) | $Z_1$<br>(PDU sent in a subslot) | $Y_2$<br>(PDU sent in a slot) | $Z_2$<br>(PDU sent in a slot) |
|---|----------------------------------|----------------------------------|-------------------------------|-------------------------------|
| $\pi/4$ -DQPSK  | 1                                | 1                                | 1                             | 1                             |
| $\pi/8$ -D8PSK  | 1                                | 2                                | 1                             | 2                             |
| 4-QAM rate=1/2, 25 kHz  | 1                                | 1                                | 1                             | 1                             |
| 16-QAM rate=1/2, 25 kHz   | 1                                | 2                                | 1                             | 2                             |
| 16-QAM rate=1, 25 kHz   | 2                                | 3                                | 2                             | 3                             |
| 64-QAM rate=1/2, 25 kHz   | 1                                | 2                                | 1                             | 2                             |
| 64-QAM rate=2/3, 25 kHz   | 2                                | 3                                | 2                             | 3                             |
| 64-QAM rate=1, 25 kHz   | 2                                | 4                                | 2                             | 4                             |
| 4-QAM rate=1/2, 50 kHz  | 1                                | 2                                | 1                             | 2                             |
| 16-QAM rate=1/2, 50 kHz   | 2                                | 3                                | 2                             | 3                             |
| 16-QAM rate=1, 50 kHz   | 2                                | 6                                | 2                             | 5                             |
| 64-QAM rate=1/2, 50 kHz   | 2                                | 4                                | 2                             | 4                             |
| 64-QAM rate=2/3, 50 kHz   | 2                                | 6                                | 2                             | 5                             |
| 64-QAM rate=1, 50 kHz   | 2                                | 8                                | 2                             | 8                             |
| 4-QAM rate=1/2, 100 kHz   | 2                                | 3                                | 2                             | 3                             |
| 16-QAM rate=1/2, 100 kHz  | 2                                | 6                                | 2                             | 5                             |
| 16-QAM rate=1, 100 kHz  | 2                                | 11                               | 2                             | 8                             |
| 64-QAM rate=1/2, 100 kHz  | 2                                | 9                                | 2                             | 8                             |
| 64-QAM rate=2/3, 100 kHz  | 2                                | 11                               | 2                             | 8                             |
| 64-QAM rate=1, 100 kHz  | 2                                | 17                               | 2                             | 8                             |
| 4-QAM rate=1/2, 150 kHz   | 2                                | 4                                | 2                             | 4                             |
| 16-QAM rate=1/2, 150 kHz  | 2                                | 9                                | 2                             | 8                             |
| 16-QAM rate=1, 150 kHz  | 2                                | 17                               | 2                             | 8                             |
| 64-QAM rate=1/2, 150 kHz  | 2                                | 13                               | 2                             | 8                             |
| 64-QAM rate=2/3, 150 kHz  | 2                                | 17                               | 2                             | 8                             |
| 64-QAM rate=1, 150 kHz  | 2                                | 22                               | 2                             | 8                             |

NOTE 1: When an MS sends a random access request on a QAM channel, it uses logical channel SCH-Q/RA in a subslot. This logical channel always uses 4-QAM modulation with rate = 1/2 in a 25 kHz bandwidth (irrespective of the bandwidth of the QAM channel). Therefore  $Y_1 = Z_1 = 1$  applies.

NOTE 2: When the BS sends a PDU on logical channel SCH-Q/B, it always uses 4-QAM modulation with rate = 1/2. The values of  $Y_2$  and  $Z_2$  are those appropriate to the bandwidth of the burst. Therefore, for PDUs sent on SCH-Q/B50,  $Y_2 = 1$  and  $Z_2 = 2$  apply; for PDUs sent on SCH-Q/B100,  $Y_2 = 2$  and  $Z_2 = 3$  apply; for PDUs sent on SCH-Q/B150,  $Y_2 = 2$  and  $Z_2 = 4$  apply.

---

## 22 LLC protocol

### 22.0 General

This clause is intended to be read together with the MAC protocol, clause 23. This clause describes the LLC sub-layer framing functions for the V+D air interface. These sub-layer functions are closely integrated with the MAC sub-layer and together the MAC and LLC form the air interface layer 2, also called DLL. An overview of the DLL architecture can be found in clause 19.

### 22.1 Overview of LLC

#### 22.1.0 General

See ETSI EN 300 392-1 [6], clause 6 for general architecture and functional description. See clause 19 for DLL architecture. See clause 20 for service description and SAPs. See clause 21 for PDU description.

The LLC procedures defined in the present document are applicable to the MS unless indicated to be valid for the BS. The LLC procedures used in the BS shall be compatible with the procedures described in the present document.

NOTE: Throughout clause 22 the word "shall" is used with service primitives for traceability reasons in the protocol model, but the primitives are not testable.

#### 22.1.1 LLC protocol

LLC protocol for TETRA contains two entities, basic link and advanced link, both accessible via the same SAP TLA-SAP. Both the data links offer two different services, i.e. unacknowledged and acknowledged information transfer mechanisms. The basic link is available whenever the MS is synchronized to a BS. The advanced link provides a better quality of service than the basic link and uses a connection on demand. There are two variants of advanced link: the original advanced link and the extended advanced link.

The basic link offers an option for extended Frame Check Sequence (FCS) to minimize the number of undetected erroneous messages. The same frame check sequence is always used on the original advanced link and may optionally be used on the extended advanced link.

The MS LLC may support up to four advanced links per service, numbered from one to four. It may use either:

- one original advanced link per service plus up to three extended advanced links per service; or
- up to four extended advanced links per service.

The various link services will be discriminated locally by a different link identifier. Link identifiers in the peer entity may be independent of these local identifiers. In the LLC itself, the distinct PDU types shall differentiate both between a basic and an advanced link and unacknowledged and acknowledged service (see clause 21). For a certain advanced link number, there can exist one acknowledged service or one unacknowledged service or both. Unacknowledged and acknowledged services are set up and disconnected independently of each other. If they coexist on the same advanced link number, they may use the same physical allocation (same timeslot or timeslots), in which case there is only one basic link associated with both the advanced link services.

If an MS LLC supports more than one advanced link per service, those advanced links may share the same physical allocation (same timeslot or timeslots). So the MS LLC may support up to four advanced links per service on a single physical allocation, in which case there is only one basic link associated with those advanced links.

Alternatively, if the MS is capable of supporting more than one physical allocation concurrently, the MS LLC may have advanced link(s) on each of the physical allocations provided that the total number of advanced links is not more than four per service.

NOTE: The above three paragraphs refer to the services available for one address. ITSIs and GTSIs in an MS are independent of each other and LLC services recognize addresses to allow concurrent basic or advanced link services. The present document does not describe how addresses affect the LLC implementation.

There is one basic link per each advanced link (or per set of advanced links if multiple advanced links share the same physical allocation) and each circuit mode service, when an ACCH is available. The number of timeslots each basic link may use is the same as the number of timeslots of the corresponding advanced link(s) or circuit mode service.

The transfer mode of an LLC link is independent of the modes of the other LLC links forming a network layer connection. As an example, a point-to-multipoint call from an MS to multiple MSs may use an advanced LLC link from the data sending MS to the BS and the unacknowledged basic LLC link from the BS to the data receiving MSs.

This LLC protocol for TETRA operates using PDUs. The PDUs are described in clause 21. The basic link LLC PDU sizes are independent of the MAC layer block sizes, because the MAC can fragment an LLC PDU if needed. For the advanced link:

- when on a  $\pi/4$ -DQPSK or D8PSK channel, the advanced link LLC protocol is constrained by the segment sizes matching the available room in MAC blocks; therefore, on a D8PSK channel, segments may be of different sizes, depending on whether they are cut to be sent using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation for the first transmission of that segment;
- when on a 25 kHz or 50 kHz QAM channel, the segment size is normally determined by the available space in a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth; when on a 100 kHz or 150 kHz QAM channel, the segment size is normally determined by the available space in half of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth. The first and last segment of a TL-SDU may be of different size.

In addition to the basic link and advanced link entities, the LLC may contain a control entity (LLC-CTRL). This entity sends and receives layer 2 signalling PDUs, using unacknowledged information transfer mechanisms. Layer 2 signalling PDUs carry various types of general signalling information relating to layer 2 functions. The layer 2 functions may be either LLC or MAC functions. However, for the purposes of the data exchange mechanisms, the layer 2 signalling PDUs are treated as LLC PDUs. In cases where the layer 2 signalling relates to a MAC function, the LLC provides the information transfer service to the MAC via the TLE-SAP.

The data link operation may use the knowledge of the multiframe structure for transmission optimization.

## 22.1.2 Communication routes of the LLC model

Figure 22.1 shows relations of the MS LLC layer protocols in the TETRA protocol stack. The MLE selects service and signal route by selecting the link identifier at the TLA-SAP. There is also an LLC flow control provided between LLC peer entities on the advanced link. The flow control is accessible to the LLC service user via a MLE-LLC control route.

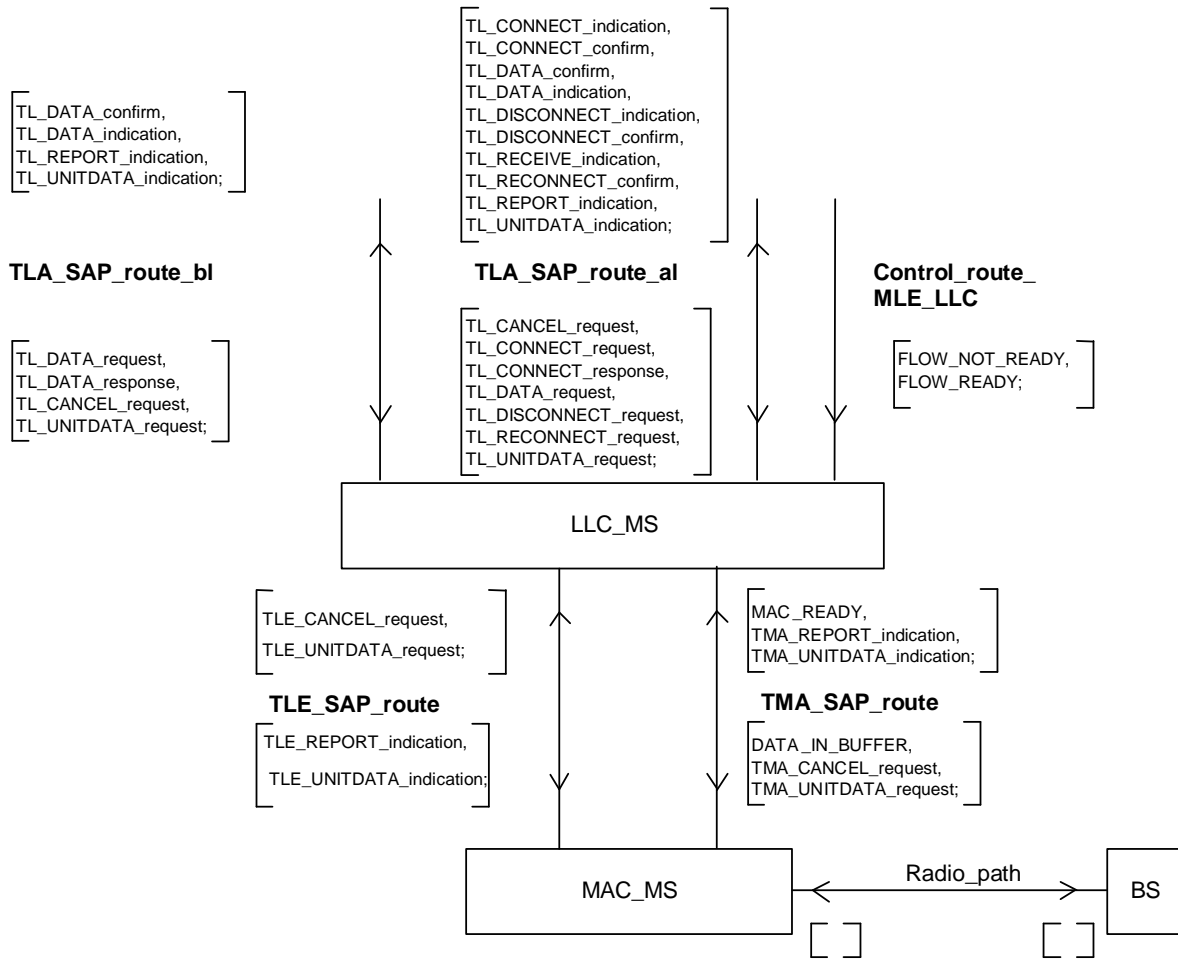

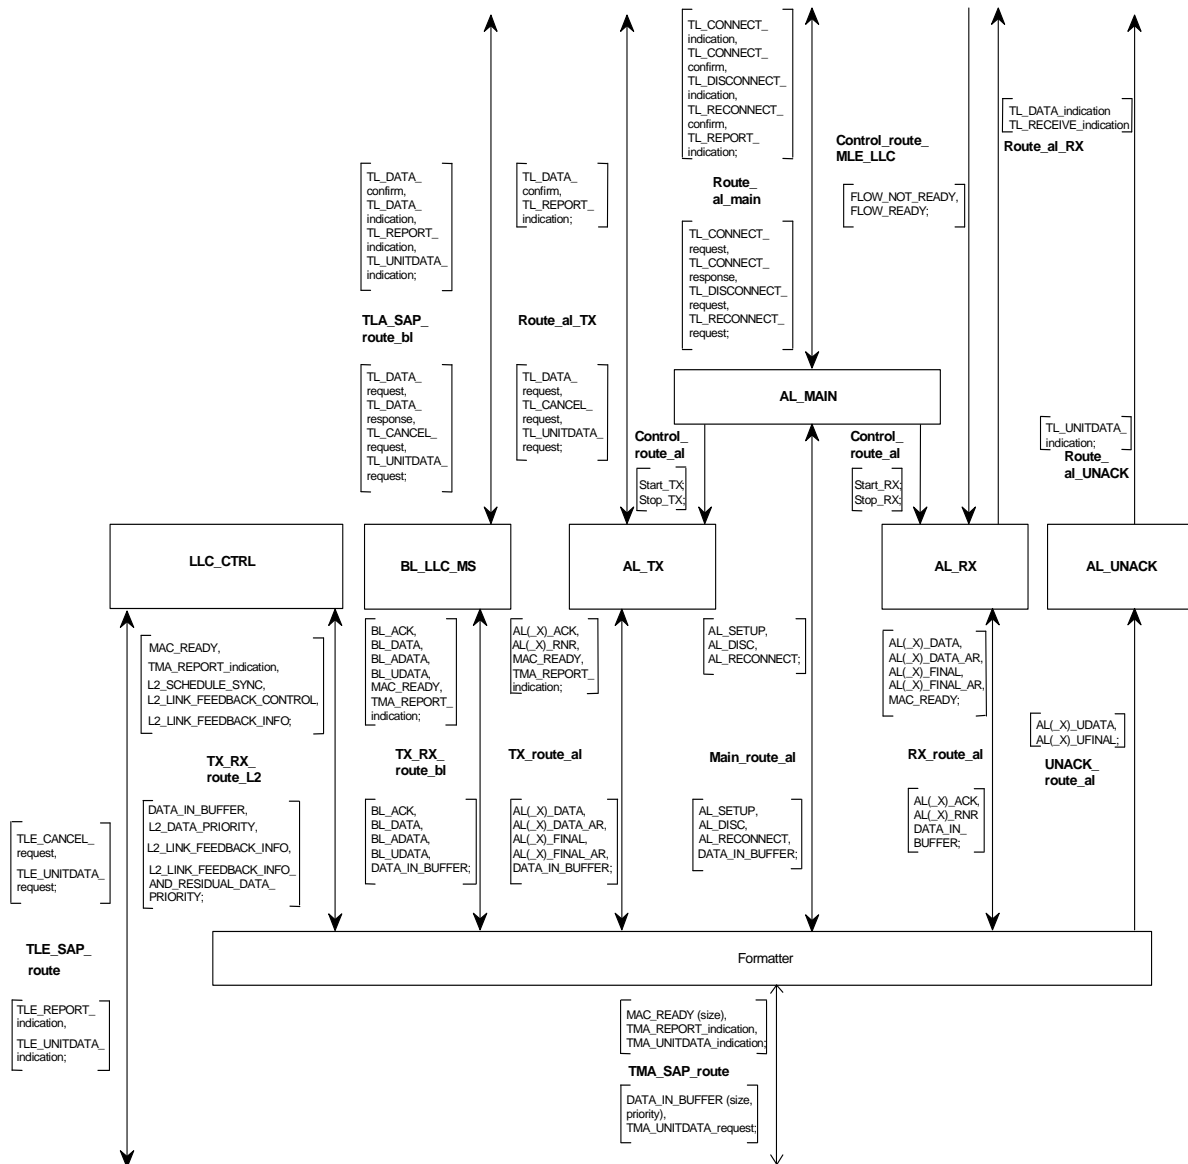

Figure 22.1: LLC relations

**Figure 22.2: LLC protocol structure**

Figure 22.2 shows the internal structure of the LLC presenting the basic and the advanced links, layer 2 signalling and layer composition of various processes.

The basic link protocol uses the following routes:

- the TLA-SAP route bl corresponds to the TLA-SAP;
- the TX-RX route bl corresponds to TMA-SAP showing LLC PDUs.

The advanced link protocol uses the following routes:

- the Route al main corresponds to the TLA-SAP for the connection set-up, LLC reconnection and disconnection;
- the Route al TX corresponds to the TLA-SAP for acknowledged data transmission;
- the Route al RX corresponds to the TLA-SAP for acknowledged data reception;
- the Control Route MLE-LLC corresponds to the TLA-SAP for flow control purposes;

- the Main route al corresponds to TMA-SAP and carries LLC PDUs for connection set-up, LLC reconnection and disconnection;
- the TX route al corresponds to TMA-SAP and carries LLC PDUs and control signals, which are used in acknowledged data transmission;
- the RX route al corresponds to TMA-SAP and carries LLC PDUs and control signals, which are used in acknowledged data reception;
- the Route al UNACK corresponds to TLA-SAP for unacknowledged service;
- the UNACK route al corresponds to TMA-SAP and carries LLC unacknowledged service PDUs;
- the Control route al carries local control of the advanced links.

The layer 2 signalling protocol uses the following routes:

- the TLE-SAP route corresponds to the TLE-SAP;
- the TX-RX route L2 corresponds to TMA-SAP and carries LLC PDUs which are used in layer 2 signalling.

Information exchange between LLC and MAC:

- the TMA-SAP route corresponds to the TMA-SAP, and carries primitives and local information exchange;
- the TLE-SAP route corresponds to the TLE-SAP, and carries primitives.

NOTE: The creation of the routes is considered to be an implementation issue and they are not shown in figure 22.2.

## 22.2 Scenarios on LLC procedures

### 22.2.0 General

This clause describes scenarios for normal TL-SDU transfer cases. For clarity many details such as TL-REPORT indication primitives are not included into message sequence diagrams.

#### 22.2.1 Basic link mode

##### 22.2.1.0 General

The basic link is available for information transfer whenever the MS is synchronized to a BS. There are two data transfer modes, acknowledged and unacknowledged PDU transfer. The acknowledged data transfer can be used for point-to-point communication and the unacknowledged data transfer can be used both for point-to-multipoint and point-to-point communication.

##### 22.2.1.1 Acknowledged PDU transfer (BL-DATA + BL-ACK)

Figures 22.3 and 22.4 show the transfer of information when the basic link is used. This protocol supports a message pair exchange based on primitives TL-DATA request and TL-DATA indication in one direction and on primitives TL-DATA response and TL-DATA confirm in the other direction as shown in figure 22.3. The TL-SDU from the left hand side entity is transmitted in the BL-DATA PDU. The TL-SDU in the TL-DATA response primitive from the right hand side LLC to the left hand side LLC is transferred in the BL-ACK PDU. That TL-SDU is not acknowledged directly with an explicit transfer of an acknowledgement PDU (though the left hand side entity may retransmit its BL-DATA PDU if it does not receive the BL-ACK PDU). Each BL-DATA PDU carries a TL-SDU number N(S), which indicates the number of the present BL-DATA PDU in that direction of information flow. The peer entity acknowledges the successful reception of this BL-DATA PDU by sending the same TL-SDU number N(R) in the acknowledgement BL-ACK PDU, see figure 22.4 for the PDU exchange.

NOTE: This protocol uses in the acknowledgement message the same message number as in the received data message in contrary to most HDLC protocols, which typically rely on a continuous message exchange and use in the acknowledgement the next expected message number.

Figure 22.3: Basic link PDU exchange with acknowledgement carrying a layer 3 message

NOTE: BL-ACK includes the response data from the service user.

Figure 22.4: Basic link data transfer and acknowledgement with a layer 3 message

In the previous scenario there was a layer 3 TL-DATA response primitive available when the BL-ACK PDU was sent. If there is no layer 3 information available, then a short acknowledgement PDU is sent as shown in figures 22.5 and 22.6. The LLC assumes that the LLC service user will normally provide a TL-DATA response to the TL-DATA indication primitive before the LLC and MAC has the next opportunity to send the BL-ACK PDU as shown above. If the TL-DATA response primitive is offered to the LLC after the sending of the BL-ACK PDU, then the LLC sends it as if it were a TL-DATA request primitive using a BL-DATA PDU, which is presented to the receiving service user as a TL-DATA indication primitive and will be confirmed, see the second set of primitives in figures 22.5 and 22.6.

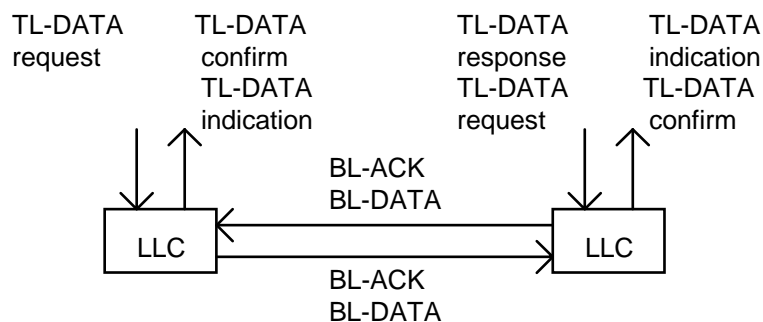

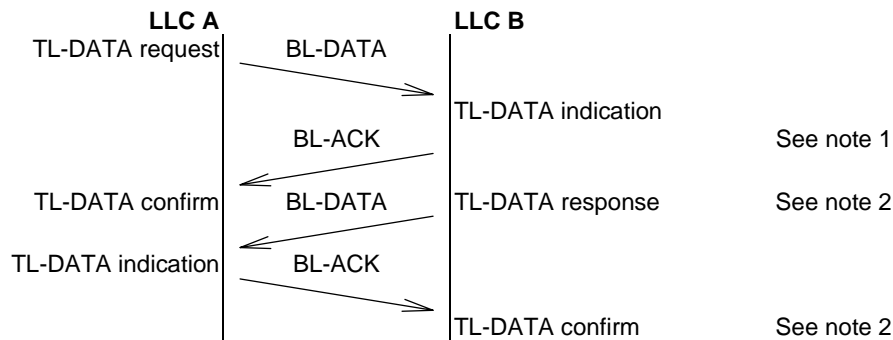

Figure 22.5: Basic link PDU exchange with LLC acknowledgement with a delayed response

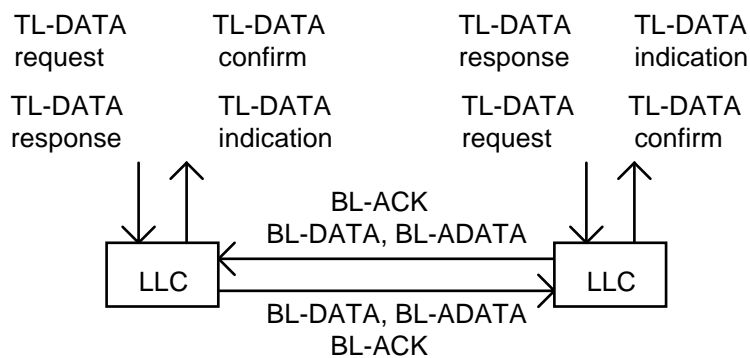

NOTE 1: When there is no TL-DATA response available, then LLC sends an acknowledgement without data.

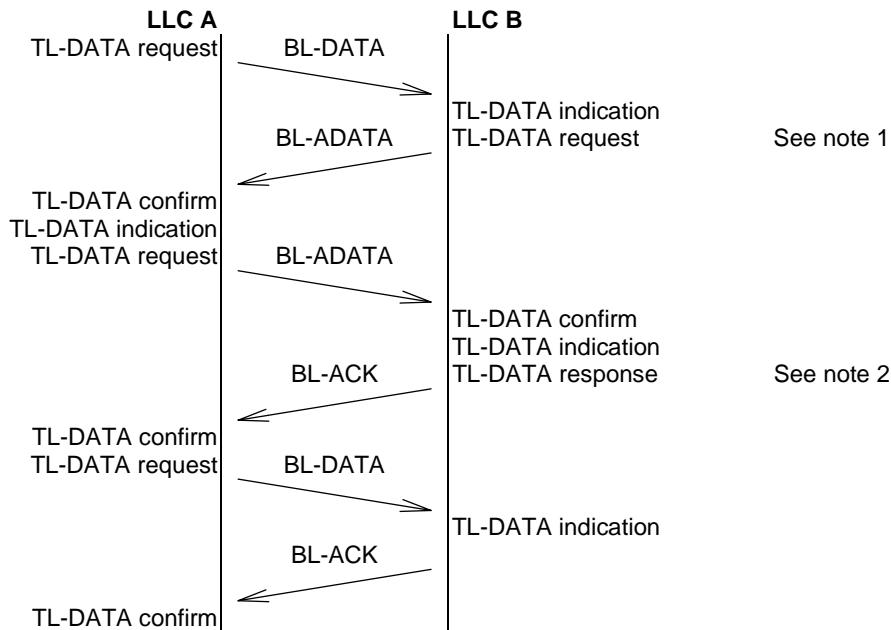

NOTE 2: The LLC transfers a delayed TL-SDU in the TL-DATA response primitive using normal acknowledged service as if it were a TL-DATA request primitive and a successful transfer will be confirmed with a TL-DATA confirm primitive to the service user.

**Figure 22.6: Basic link data transfer and acknowledgement with a delayed layer 3 response**

The basic link also allows concurrent data transfer in both directions independent of each other as shown generally in figure 22.7 and as an example in figure 22.8. A TL-DATA request primitive is sent in a BL-DATA PDU from the LLC A. The LLC B may combine the acknowledgement and the user data from a TL-DATA request primitive into a BL-ADATA PDU. At the LLC A receiver the acknowledgement will be delivered to the service user in a TL-DATA confirm primitive and the user data is delivered in an independent TL-DATA indication primitive. The example continues with the second TL-DATA request primitive and with the corresponding combined BL-ADATA PDU. To the resulting TL-DATA indication primitive the LLC B responds with a TL-DATA response primitive and the user data is sent in a BL-ACK PDU. This is delivered to the service user in a TL-DATA confirm primitive and there is no explicit acknowledgement sent to that data. The next user data PDU from the LLC A will be a BL-DATA PDU and it is in this example acknowledged by a BL-ACK PDU without data. If the user does not want to send a response but an independent data, see figure 22.8, note 1, then a TL-DATA request primitive is used and the LLC will acknowledge the received data either with a BL-ACK or with a BL-ADATA PDU. In figure 22.7 there are two sets of service primitives; the upper and lower are used in the information flow from left to right and from right to left respectively.

**Figure 22.7: Concurrent independent message exchange in both directions**

NOTE 1: Service user offers a data request instead of a response.

NOTE 2: There may be also a data response, which is carried in BL-ACK PDU and will not be acknowledged directly.

**Figure 22.8: Concurrent independent message exchange in both directions**

The LLC sends reports, or reports on the progress of data sending, to the service user based on information from MAC layer. Those reports will be explained in the protocol description and are not presented here.

In this protocol, a single TL-SDU, in a BL-DATA or BL-ADATA PDU, is sent and acknowledged at a time and the window size is equal to 1. There is no peer-to-peer flow control mechanism for the basic link.

### 22.2.1.2 Unacknowledged data transfer (BL-UDATA PDU)

Unacknowledged mode of operation may be used for sending data from the base station to a group of MSs (point-to-multipoint) as shown in figures 22.9 and 22.10, where the BL-UDATA PDU is used to transfer information. No responses nor acknowledgements are expected to a BL-UDATA PDU. The sending LLC entity may repeat a BL-UDATA PDU several times to increase the probability of a correct reception. The receiving protocol does not suppress received duplicates. The unacknowledged basic link service does not guarantee in-order delivery at the receiving entity if the BL-UDATA PDU is repeated. The LLC may send a report or reports on the progress of data sending to the service user.

The BL-UDATA PDU may be used also for sending data from the base station to an individual MS (point-to-point) or from an MS to the base station.

**Figure 22.9: PDU exchange in unacknowledged mode**

**Figure 22.10: Basic link data transfer in unacknowledged mode**

### 22.2.1.3 Unacknowledged data transfer with presence indication (BL-DATA + BL-ACK PDU)

This clause describes how a BS may implement presence checking in group call establishment.

This operation mode of the BS allows sending of unacknowledged data and requesting a low level presence indication from one or more recipient MS. The presence indication message carries only indication that at least one MS has received the message correctly and shall not contain a TL-SDU, see figures 22.11 and 22.12. In response to the TL-DATA request primitive with a presence indication parameter the base station sends a normal BL-DATA PDU and waits for an answer from one or more MSs. The MS LLC sends a normal acknowledgement, which is detected in the BS without actually decoding it especially if many MSs have answered at the same time. The BS LLC does not re-send the BL-DATA PDU to get back a decodeable BL-ACK PDU, but it may send BL-DATA PDU more than once for more reliable data transfer.

**Figure 22.11: Basic link data transfer with presence indication**

**Figure 22.12: Basic link data transfer with presence indication**

## 22.2.2 Advanced link

### 22.2.2.0 General

The advanced link provides two data transfer services, i.e. acknowledged and unacknowledged PDU transfer. The acknowledged data transfer can be used for point-to-point communication and the unacknowledged data transfer is intended to be used for point-to-multipoint communication, but may also be used for point-to-point information transfer on the downlink. Both services of the advanced link need to be set up before they can be utilized. The life of an advanced link comprises a connection set-up, data transfer and connection release. The life time of an advanced link may be limited or unlimited. After cell reselection, depending on the capabilities of the MS and SwMI, the advanced link may be reconnected, with the same parameters (e.g. QoS, timers, counters) as were used on the previous cell.

The advanced link protocol can send multiple TL-SDUs before an acknowledgement shall be sent or is received. The data transmitting station may send up to N.272 TL-SDUs before requesting and receiving a specific acknowledgement. The LLC may re-send TL-SDUs under a request from the data receiving LLC entity or due to a lack of an acknowledgement.

The advanced link segments TL-SDUs which are too long to be carried in one advanced link unit, and applies automatic selective re-transmission to badly received segments:

- When on a  $\pi/4$ -DQPSK or D8PSK channel, the segment size is determined by the available room in a MAC transmission unit (MAC block). Therefore, on a D8PSK channel, segments may be of different sizes, depending on whether they are cut to be sent using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation for the first transmission of that segment.
- When on a 25 kHz or 50 kHz QAM channel, the segment size is normally determined by the available space in a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth; when on a 100 kHz or 150 kHz QAM channel, the segment size is normally determined by the available space in half of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth. The first and last segment of a TL-SDU may be of different size.

There are two variants of advanced link: the original advanced link and the extended advanced link. The type of advanced link is negotiated during the call set-up.

For Conventional Access (CA), the BS indicates whether it supports:

- the original advanced link, using the "BS service details" element in the D-MLE-SYSINFO and D-MLE-SYSINFO-Q PDUs (see clause 18);
- both original and extended advanced links, using also the "extended services broadcast" element in the SYSINFO and SYSINFO-Q PDUs (see clause 21).

For Direct Access (DA), the BS shall support both original and extended advanced links (unless the "system wide services" element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "system wide services temporarily not supported", in which case support of advanced links by the BS is optional).

NOTE: CA is a method of operation in which the main carrier is a phase modulation carrier. DA is a method of operation in which the main carrier is a QAM carrier.

The MS indicates whether it supports the original advanced link and/or extended advanced link(s) using the "class of MS" element in the U-LOCATION UPDATE DEMAND PDU (see clause 16).

The MS is only permitted to support one original advanced link per service, whereas it may support more than one extended advanced link per service, provided that the total number of advanced links (original plus extended) is not more than four per service. (This refers to the services available for one address.)

- For the original advanced link, there is not explicit link numbering in the data transfer and acknowledgement PDUs; the advanced link number is implicitly assumed to be as indicated in the set-up message for the original advanced link. The FCS is mandatory for the original advanced link.
- In the extended advanced link, there is explicit link numbering in all the data transfer and acknowledgement PDUs. The FCS is optional for the extended advanced link. And the extended advanced link has a larger TL-SDU sequence number than the original advanced link, enabling a larger TL-SDU window size.

The PDUs used for advanced link set-up, release and LLC reconnection are the same for the original advanced link and the extended advanced link. However there are different PDUs for the data transfer and acknowledgements; extended advanced link PDUs are indicated by "-X" included in the name of the corresponding original advanced link PDU.

EXAMPLE: For example, the AL-DATA PDU is used on the original acknowledged advanced link to send segments other than the last - and the equivalent PDU for the extended advanced link is denoted AL-X-DATA.

### 22.2.2.1 Setting up the connection mode (AL-SETUP PDU)

The advanced LLC link connection for acknowledged service shall be negotiated between the two LLC entities as described in figures 22.13, 22.14 and 22.15. Either the MS or BS may initiate the advanced link connection set-up. A new connection set-up using the same advanced link number (and address) during an already existing connection overrides it and performs a link reset.

The resulting connection mode advanced link may coexist with an unacknowledged advanced link, refer to clause 22.2.2.2.

A new acknowledged advanced link set-up using a different advanced link number or address during an already existing acknowledged advanced link (or already existing acknowledged advanced links) sets up a new, independent, advanced link.

The connection request contains all parameters for negotiation (see notes 1 and 2):

- the maximum length of the TL-SDU N.271;
- the allowed number of TL-SDU retransmissions before LLC gives up N.273;
- the LLC TL-SDU window size N.272;
- the number of retransmissions of a segment N.274;
- optionally, the number of  $\pi/4$ -DQPSK timeslots requested per TDMA frame N.264 (see notes 2 and 3);
- optionally, the requested mean value for the data transfer throughput (see notes 2 and 3);
- advanced link symmetry; and
- indication of whether the advanced link is an original or extended advanced link.

The negotiation uses AL-SETUP PDUs.

NOTE 1: These constants are part of the quality of service negotiation and are transmitted to the peer side. Depending on the mobile class and base station services, the peer entity may wish to respond with a lower quality of service or even refuse the connection set-up.

NOTE 2: During the advanced link negotiation, the peer entity is only permitted to respond with a lower quality of service or refuse the connection set-up; it is not permitted to respond with a higher quality of service. Permitted parameter negotiations are as follows:

- Parameters N.264, N.271, N.273 and N.274 may only be numerically lower or equal in the response AL-SETUP.
- If an extended advanced link has been proposed, the peer entity may offer an original advanced link (in which case it may respond to the augmented AL-SETUP PDU with either an augmented AL-SETUP PDU for the original advanced link or a non-augmented AL-SETUP PDU).
- If an original advanced link has been proposed using an augmented AL-SETUP PDU, the peer entity may respond with either an augmented AL-SETUP PDU for the original advanced link or a non-augmented AL-SETUP PDU.
- The TL-SDU window size N.272 may only be numerically lower or equal in the response AL-SETUP PDU.

If the peer entity is responding to an augmented AL-SETUP PDU with a non-augmented AL-SETUP PDU, this means that the TL-SDU window size in the non-augmented response AL-SETUP PDU is numerically lower than or equal to the TL-SDU window size that was proposed in the augmenting part of the augmented AL-SETUP PDU.

- The data transfer throughput may only be negotiated if it is not equal to  $110_2$ . It may only be numerically lower or equal in the response AL-SETUP; however it cannot be changed to  $110_2$ .
- The connection width may only be numerically lower or equal in the response, and may only be changed if the data transfer throughput is not equal to  $110_2$ .
- The advanced link symmetry may only be numerically lower or equal in the response. If an asymmetric phase modulation advanced link was proposed and the peer entity offers a symmetric phase modulation advanced link, parameter N.264 in the response AL-SETUP may only be numerically lower than or equal to the maximum of the two values of N.264 proposed for the uplink and downlink for the asymmetric advanced link.

Other parameter negotiations are not permitted.

The advanced link service (acknowledged service or unacknowledged service) and the advanced link number N.261 are not negotiable.

NOTE 3: The AL-SETUP PDU may contain information related to phase modulation radio resources; this facility in the AL-SETUP PDU provides radio resource information only in terms of  $\pi/4$ -DQPSK timeslots:

- In the case of a specified phase modulation connection, the number of  $\pi/4$ -DQPSK timeslots requested per TDMA frame indicates the maximum transmission rate for this advanced link in terms of  $\pi/4$ -DQPSK timeslots; and the mean data transfer throughput information is given relative to the number of  $\pi/4$ -DQPSK timeslots requested per TDMA frame. The actual channel allocated by the SwMI may comprise fewer or more timeslots than the negotiated number of  $\pi/4$ -DQPSK timeslots per TDMA frame (within the MS's declared capabilities). Also, if the MS has indicated that it supports D8PSK channels, the BS should regard the radio resource information as a request for either a  $\pi/4$ -DQPSK or D8PSK connection.
- In the case of an unspecified phase modulation connection, the AL-SETUP PDU indicates a request for any phase modulation channel (within the capabilities of that MS) i.e. without requesting a specific number of timeslots per TDMA frame. If the MS has indicated that it supports D8PSK channels, the BS should regard this as a request for either a  $\pi/4$ -DQPSK or D8PSK connection.

Alternatively the AL-SETUP PDU may provide no information related to radio resources, for example, if the MS wishes the BS to choose any appropriate channel (within the capabilities of that MS and using any QoS information negotiated by the SNDSCP during PDP context activation).

NOTE 4: If the MS is using multiple advanced links, those advanced links may share the same physical allocation, in which case the allocated channel may need to comprise more timeslots (and/or a wider RF bandwidth) than would be needed for one of the advanced links.

The resulting connection will support two-way exchange of information between the peer LLC entities.

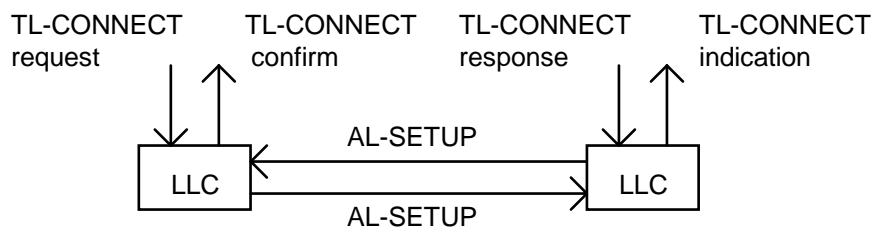

Figure 22.13: PDU setting up the advanced link

Figure 22.14: Advanced link set-up

NOTE 5: On establishment of an advanced link, the LLC prepares an AL-SETUP PDU with a set-up report "service definition" if the corresponding advanced link is not already set up. However, after advanced link continuation, the MS LLC may think that there is already an established advanced link and therefore use a set-up report value of "reset". Then the BS LLC entity should start normal connection establishment as if the received report were "service definition".

NOTE 1: Proposed QoS is not acceptable and a new QoS is proposed. The service negotiation may be performed as a direct negotiation between the LLC entities.

NOTE 2: The lower QoS is accepted.

**Figure 22.15: Advanced link set-up to a lower quality of service**

Figure 22.14 presents a message sequence diagram for an advanced link set-up, when the LLC B accepts the quality of service proposed by the LLC A. If the receiving station replies with a lower parameter setting, the transmitting station shall confirm those lower values and use these negotiated parameters for the advanced link as shown in figure 22.15. A receiving station shall not reply with higher parameter setting. On the other hand, the receiving station may refuse the connection by returning a TL-DISCONNECT request primitive (AL-DISC PDU).

The initial connect request shall set the TL-SDU and segment counters to the default values prior to the first transmission in both information flow directions.

If the LLC cannot support the advanced link, it may send an AL-DISC PDU, see figure 22.16.

**Figure 22.16: Unsupported service indication**

### 22.2.2.2 Setting up the unacknowledged transfer mode (AL-SETUP PDU)

The advanced LLC link parameters shall be informed to the future participants of the unacknowledged transfer mode before the data transfer may commence successfully as described in figures 22.17 and 22.18. A new unacknowledged advanced link set-up using the same advanced link number and address during an already existing unacknowledged advanced link only modifies advanced link parameters without a reset functionality e.g. TL-SDU numbering shall continue without interruption. This set-up does not affect to the existing acknowledged advanced link service, if any, refer to clause 22.2.2.1.

A new unacknowledged advanced link set-up using a different advanced link number or address during an already existing unacknowledged advanced link (or already existing unacknowledged advanced links) sets up a new, independent, advanced link.

The set-up indication contains all relevant parameters for the unacknowledged advanced link: the maximum length of the TL-SDU N.271, the maximum number of TL-SDU retransmissions N.282, the LLC TL-SDU window size N.281 and indication of whether the advanced link being set up is an original or extended advanced link. The AL-SETUP PDU transmits these parameters. The AL-SETUP PDU may be sent several times (N.282+1 times) to increase the probability of correct reception. The further connection attempts for the same link are not passed to the service user unless the parameters in the following AL-SETUP PDUs change.

The resulting unacknowledged advanced link will support one-way exchange of information from the entity which sends the set-up information to the other peer LLC entities. The receiving entity may not be capable to conform to the selected parameters and may neglect the set-up.

Figure 22.17: Unacknowledged transfer mode set-up of the advanced link

Figure 22.18: Unacknowledged transfer mode set-up of the advanced link

The unacknowledged advanced link entities shall set the TL-SDU and segments counters to the default values prior to the first transmission.

### 22.2.2.3 Data exchange in the connection mode (AL-DATA or AL-X-DATA PDU)

After the connection set-up the advanced LLC link is ready for a two-way exchange of information between the two peer LLC entities although actual information flow could be unidirectional and the other direction is used only for acknowledgements. The information flows in both directions (uplink and downlink) are independent of each other. Each AL-DATA or AL-X-DATA PDU contains two numbers: the actual TL-SDU number  $N(S)$  and the absolute position of the segment inside the TL-SDU called segment sequence number  $S(S)$ . The segment sequence number is used in selective re-transmission in the AL-ACK or AL-X-ACK PDU. The AL-X-DATA PDU also contains the advanced link number.

The remainder of this clause describes scenarios for data exchange in the connection mode on the original advanced link. The methods of data exchange in the connection mode on an extended advanced link are similar to the methods on the original advanced link - except that PDUs AL-X-DATA, AL-X-DATA-AR, AL-X-FINAL, AL-X-FINAL-AR, AL-X-ACK and AL-X-RNR are used instead of PDUs AL-DATA, AL-DATA-AR, AL-FINAL, AL-FINAL-AR, AL-ACK and AL-RNR respectively.

**NOTE:** If an MS is using more than one advanced link, the data transfer procedures for each advanced link operate independently of the data transfer procedures for the other advanced link(s).

Data transfer in the advanced LLC link can be either unidirectional or bidirectional. In both cases data sending and data acknowledgements use the same PDUs and protocol. In the first case, the transfer flow is shown in figures 22.19 and 22.20 for the original advanced link. In this example LLC A sends a segmented TL-SDU using AL-DATA PDUs and marks the last segment of the TL-SDU by using an AL-FINAL-AR PDU. In reply to the AL-FINAL-AR PDU the data receiving LLC shall generate an acknowledgement using an AL-ACK PDU. The data sending LLC informs the service user of the correct transfer of the layer 3 TL-DATA by issuing a TL-DATA confirm primitive when a whole TL-SDU has been acknowledged. The data receiving BS LLC entity informs the service user of the incoming of data by issuing a TL-RECEIVE indication primitive.

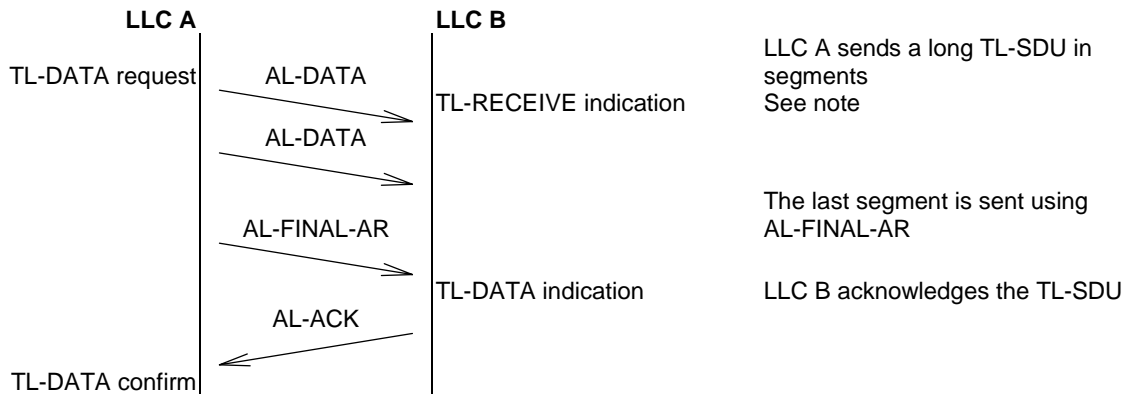

Figure 22.19: PDU exchange in a unidirectional transfer on the original advanced link

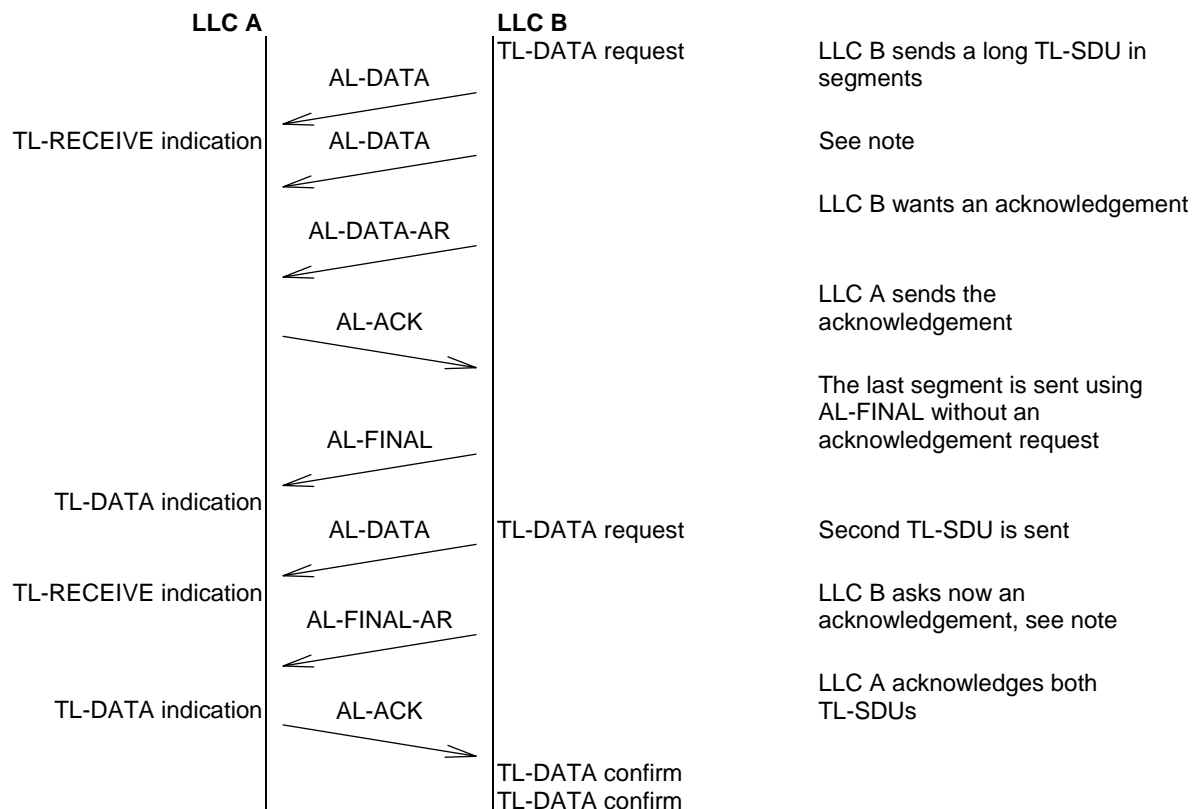

NOTE: LLC B refers to BS LLC entity in this figure. Exact mechanism when to send the TL-RECEIVE indication primitive is outside the scope of the present document.

**Figure 22.20: PDU exchange in a unidirectional transfer on the original advanced link**

The data sending LLC entity may request an acknowledgement from the peer entity at any time by using AL-DATA-AR or AL-FINAL-AR PDUs in place of the AL-DATA and AL-FINAL PDUs respectively. The data sender may continue transmission of data without waiting for the requested acknowledgements, if allowed by the SDU window size. In figure 22.21 the LLC B requests an acknowledgement in the middle of sending a TL-SDU and later does not request an immediate acknowledgement to the complete TL-SDU.

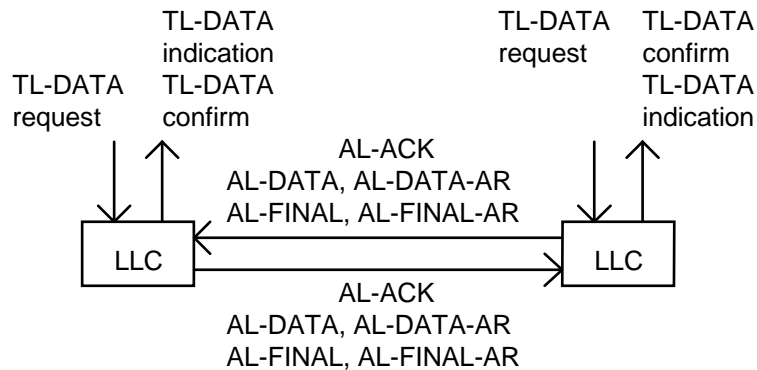

The data receiver may send an AL-ACK PDU at any time in addition to the requested acknowledgements, see also clause 22.2.2.7.

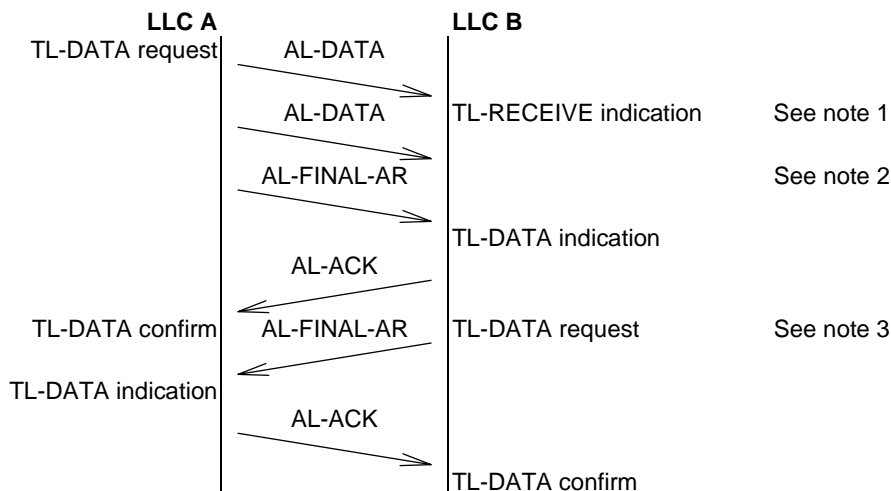

NOTE: LLC A refers to BS LLC entity in this figure. Exact mechanism when to send the TL-RECEIVE indication primitive is outside the scope of the present document.

**Figure 22.21: A longer PDU transfer on the original advanced link**

An example of bidirectional information transfer flow is shown in figures 22.22 and 22.23. The LLC A sends a message to the LLC B, and the LLC B responds with another message. The LLC A starts the sending by a segmented TL-SDU using AL-DATA PDUs and marks the last segment of the TL-SDU by using AL-FINAL-AR PDU. The LLC B delivers the received TL-SDU to the service user as a TL-DATA indication primitive. The LLC B generates an acknowledgement AL-ACK PDU as a response to the AL-FINAL PDU. The acknowledged TL-SDU shall be indicated to the data sending service user by a TL-DATA confirm primitive.

**Figure 22.22: Bi-directional data transfer on the original advanced link**

NOTE 1: LLC B refers to BS LLC entity in this figure. Exact mechanism when to send the TL-RECEIVE indication primitive is outside the scope of the present document.

NOTE 2: The last segment is sent using AL-FINAL-AR.

NOTE 3: LLC B sends a responding or independent TL-SDU.

**Figure 22.23: Bi-directional PDU transfer on the original advanced link**

The LLC can accept more than one TL-SDU for sending before completing the transfer of the previous TL-SDU. The LLC may also modify the sending order of TL-SDUs depending on the priorities of those SDUs, but all already started transmissions need to be completed before a new higher priority TL-SDU (non pre-emptive) may be transferred successfully. The LLC entity could also start sending of TL-SDUs at any time independently of the state of the other transfer direction.

Highest priority transmissions across an advanced link may reset the link to get fast access. This action may corrupt the ongoing lower priority transmission.

### 22.2.2.4 Data exchange in the unacknowledged transfer mode (AL-UDATA or AL-X-UDATA PDU)

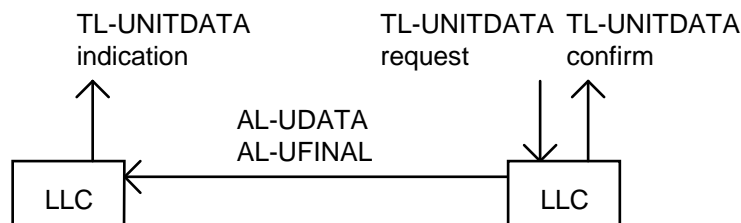

After the unacknowledged data transfer set-up the advanced LLC link is ready for a one-way exchange of information. The service user data is transmitted in AL-UDATA or AL-X-UDATA PDUs. The AL-UDATA or AL-X-UDATA PDU contains two numbers: the actual TL-SDU number  $N(S)$  and the absolute position of the segment inside the TL-SDU called segment sequence number  $S(S)$ . The segment sequence number is used in the rebuilding of the received TL-SDU from segments. The AL-X-UDATA PDU also contains the advanced link number.

The data transfer flow is shown in figures 22.24 and 22.25 for the original advanced link. The methods of unacknowledged data exchange on an extended advanced link are similar to the methods on the original advanced link - except that PDUs AL-X-UDATA and AL-X-UFINAL are used instead of PDUs AL-UDATA and AL-UFINAL respectively.

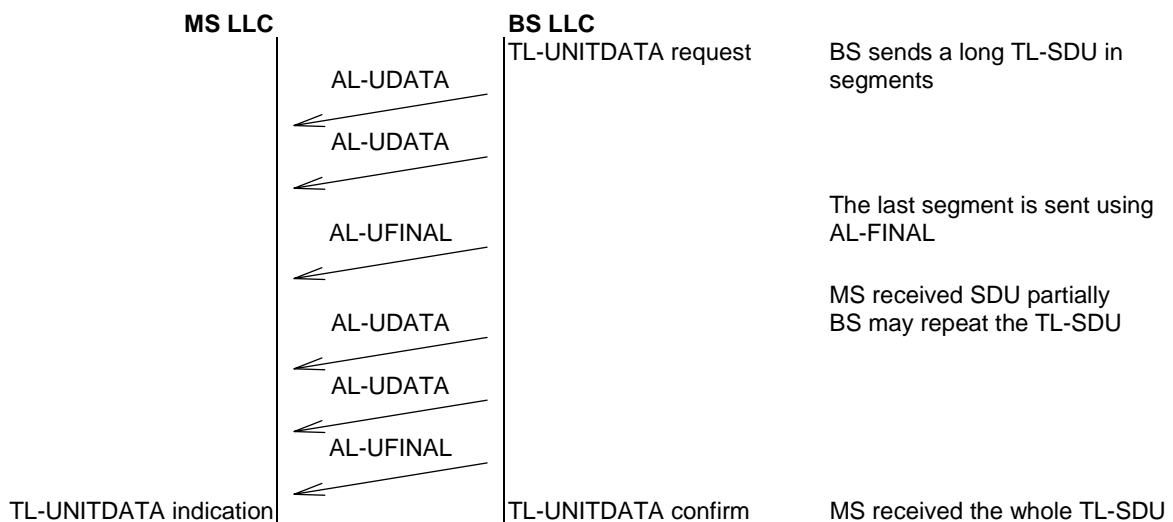

**NOTE:** If an MS is receiving more than one unacknowledged advanced link, the data transfer procedures for each advanced link operate independently of the data transfer procedures for the other advanced link(s).

In the example shown, the BS LLC sends a segmented TL-SDU using AL-UDATA PDUs and marks the last segment of the TL-SDU by using an AL-UFINAL PDU. The BS may send the TL-SDU several times up to maximum retransmissions ( $N.282$ ) to increase the reception probability (and using the same segmentation for each repetition).

The data receiving LLC entity delivers the TL-SDU to the service user in a TL-UNITDATA indication primitive. The data sending entity may inform the completion of all repetitions to the service user using an informal TL-UNITDATA confirm primitive.

**Figure 22.24: PDU sending in a unidirectional transfer on the original advanced link**

**Figure 22.25: PDU sending in a unidirectional transfer on the original advanced link**

The BS LLC may send repetitions of up to  $N.281$  TL-SDUs in any order, but either the oldest TL-SDU within that SDU-window with all repetitions shall be sent, or transmission of the oldest TL-SDU within the SDU-window shall be stopped, before a new TL-SDU may commence. The BS LLC may also modify the sending order of TL-SDUs depending on the priorities of those SDUs.

The data receiving entity may combine segments from multiple transmissions of the same TL-SDU in order to reassemble a complete TL-SDU.

### 22.2.2.5 Window mechanism

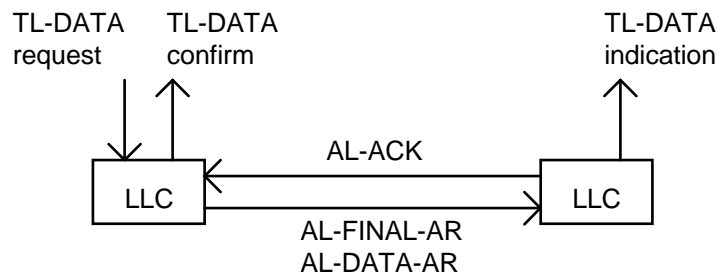

In the advanced link LLC protocol there is a window mechanism for TL-SDU transmissions. The window mechanism allows more than one TL-SDU and LLC data PDU respectively to be sent before required acknowledgements stop LLC transmissions. The TL-SDU window size  $N.272$  is negotiated during the advanced link set-up, refer to clause 22.2.2.1. The maximum window size that may be negotiated is:

- 3 for the original advanced link; or
- 15 for an extended advanced link.

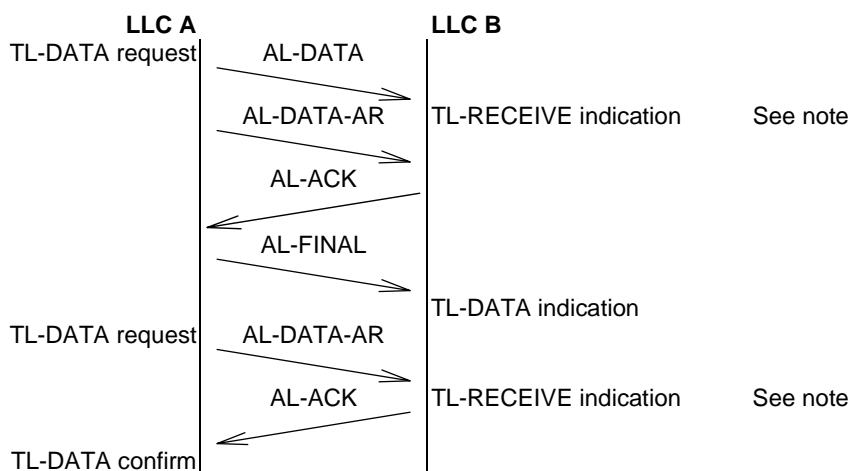

The data receiving LLC entity may acknowledge each TL-SDU as soon as it is fully received, but the data sending LLC entity may continue to send up to a total of  $N.272$  TL-SDUs before receiving acknowledgements for the previous TL-SDUs. (For window size  $N.272 = 1$ , the data receiving LLC entity acknowledges each TL-SDU before the data sending LLC entity may continue with the next TL-SDU.)

During a segment transmission the data sending LLC entity may force a sending of an acknowledgement whenever it sends the last segment of a TL-SDU, which is sent as the AL-FINAL-AR or AL-X-FINAL PDU, refer to clause 22.2.2.3. The data sending LLC entity may also request an acknowledgement at any time using an AL-DATA-AR or AL-X-DATA-AR PDU type, which also initiates an acknowledgement as soon as possible. This is illustrated for the original advanced link in figures 22.26 and 22.27.

This window mechanism shall not be used for flow control purposes, refer to clause 22.2.2.7.

**Figure 22.26: PDU exchange for forced acknowledgement on the original advanced link**

NOTE: LLC B refers to BS LLC entity in this figure. Exact mechanism when to send the TL-RECEIVE indication primitive is outside the scope of the present document.

**Figure 22.27: Forced acknowledgement on the original advanced link**

### 22.2.2.6 Selective re-transmission of segments (AL-ACK or AL-X-ACK PDU)

The selective re-transmission is based on the segments (LLC PDUs) into which the data transmitting LLC divides a TL-SDU for sending. The data receiving LLC informs the data transmitting LLC which segments are not received correctly, and then the data transmitting LLC sends the missing segments in the later transmissions until the whole TL-SDU is received correctly as recognized by the MAC layer error detection. The whole TL-SDU may still be erroneous, and the data receiving entity shall ask for a re-transmission when an error in the TL-SDU is detected by the frame check sequence.

Figure 22.28 shows an example of a selective re-transmission sequence for the original advanced link. Line a) of figure 22.28 shows three TL-SDUs, which the data transmitting LLC divides into segments as shown in the line b). The end of each SDU is marked by "F" and the data transmitting LLC sends that segment using a AL-FINAL PDU. The SDU window size is 2 in this example.

The data transmitting LLC plans to send segments as shown on line b) of figure 22.28 and starts to send them in sequence using AL-DATA PDUs for all but the last one which it sends using AL-DATA-AR PDU marked by "A". The data receiving LLC receives correctly segments 1, 2, 4, 5 from the first SDU as shown on line c), and sends the first acknowledgement (ACK) as requested by the data sending entity. The acknowledgement contains bit maps as shown on line e) and corresponding segment numbers are shown on line f). The first part of the ACK (1/3) indicates the first segment, which is not received correctly, in this example segment number 3 in the first SDU and a bit map from that segment onwards. The acknowledgement tells that all segments before the 3rd segment of the first SDU (1/3) are received correctly and that segment 3 of the first SDU is not yet received correctly. Then the bitmap shows that segments 4 and 5 are received correctly.

The data transmitting LLC then modifies its transmission and adds those segments, which were not acknowledged or sent i.e. 3 and 6 from the first SDU (1/3 and 1/6), before continuing transmission of new segments in this case from the second SDU. The last segment of the second SDU is sent as AL-FINAL-AR PDU marked "F/A". The second and third acknowledgements on line d) indicate that again segments 3 and 6 from the first SDU are not yet received correctly, but the second SDU is received totally and correctly (2/A). The data transmitting LLC then re-sends segments 3 and 6 of the first SDU and cannot continue to the third SDU due to SDU window size of two in this example.

The data receiving LLC misses again the segment number 3 of the first SDU as shown on line g) and the data receiving LLC sends acknowledgement after receiving the 6th and final segment of the first SDU. The first acknowledgement indicates that only the third segment of the first SDU is not yet received correctly. The data transmitting LLC then re-sends the missing segment of the first SDU and after receiving the second acknowledgement on the line h) can send the third SDU, which fits into the new SDU window. That SDU is received correctly as indicated by each segment CRC, but the total frame check sequence does not match and the data receiving LLC sends an acknowledgement indicating a re-sending request (3/F) of the third SDU. After re-sending on line j) the third SDU is this time received correctly and acknowledged on line k) (3/A).

In this example the data receiving LLC will deliver the first TL-SDU to the MLE only after sending the second acknowledgement on the line i), which indicates that the first SDU is correctly received. The second SDU is already correctly received and acknowledged by the second acknowledgement on the line d), but the data receiving LLC cannot deliver it before the first SDU is received in order to keep the SDUs in the correct sequence.

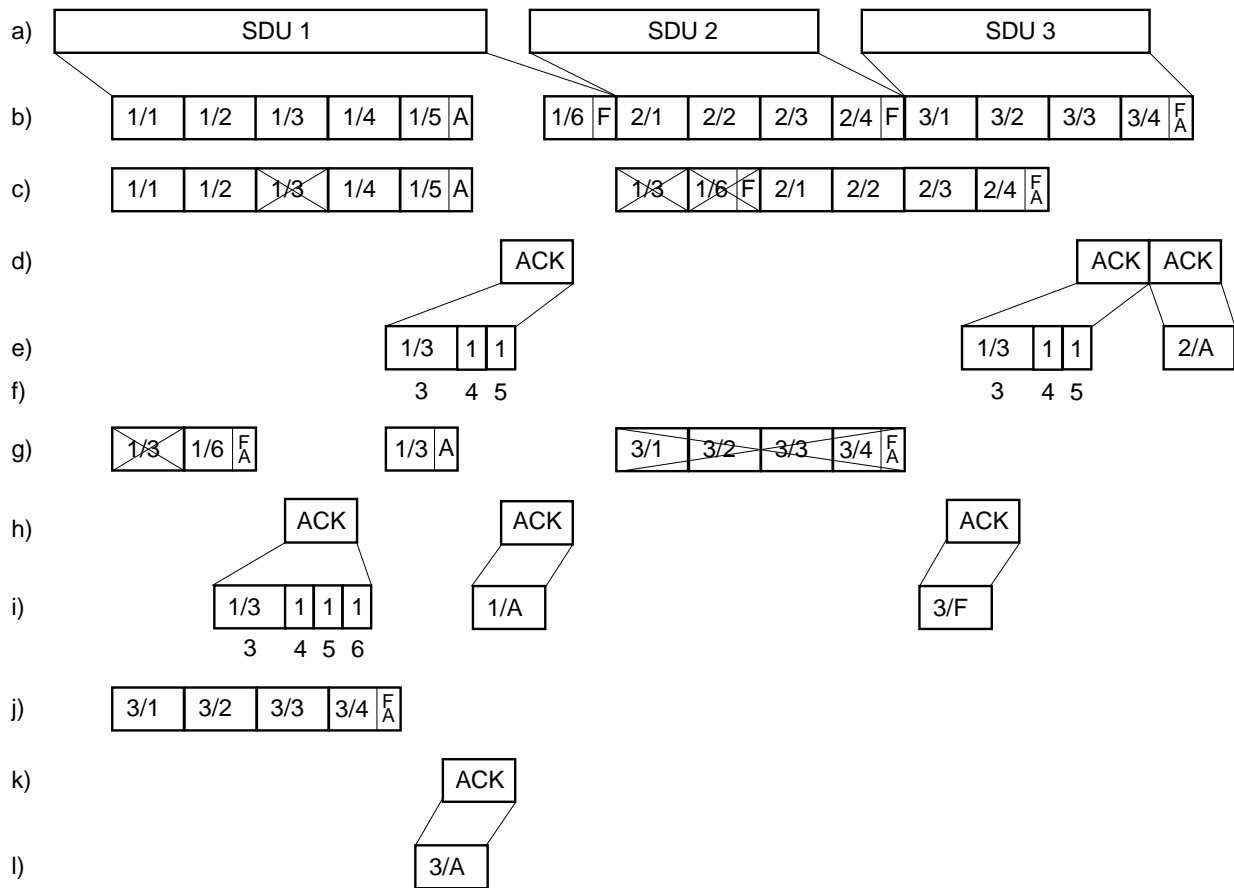

Figure 22.28: Selective re-transmission example

If the AL-FINAL-AR is lost and there is no more data to send or the transmission window is closed and the last acknowledgement is also lost, then the data sending entity may repeat the whole last sending or only the segments which were sent with the acknowledgement request.

### 22.2.2.7 Flow control (AL-RNR or AL-X-RNR PDU)

The data receiving advanced link entity may at any time request its peer entity to stop transmission of data PDUs on an advanced link by sending an AL-RNR PDU (for the original advanced link) or an AL-X-RNR PDU (for an extended advanced link). The AL-RNR or AL-X-RNR PDU replaces the AL-ACK or AL-X-ACK PDU, when the data receiver is not ready to receive new PDUs. The re-transmission of the segments or PDUs indicated in the AL-RNR or AL-X-RNR PDU shall continue. The data transmission may continue after the data receiving entity has sent an AL-ACK or AL-X-ACK PDU for this advanced link. This is illustrated for the original advanced link in figures 22.29 and 22.30.

The receiver not ready indication is valid from the last received AL-RNR or AL-X-RNR PDU for this advanced link for the duration of T.271 s, after which the data transmitter may try to re-start data sending.

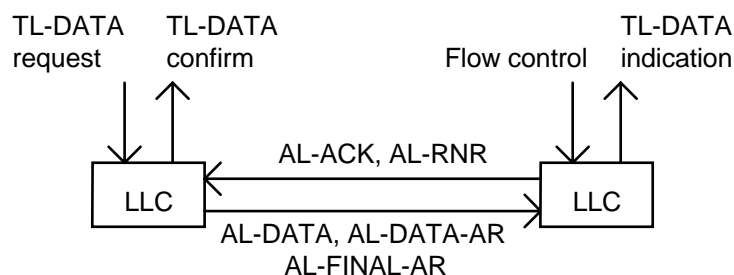

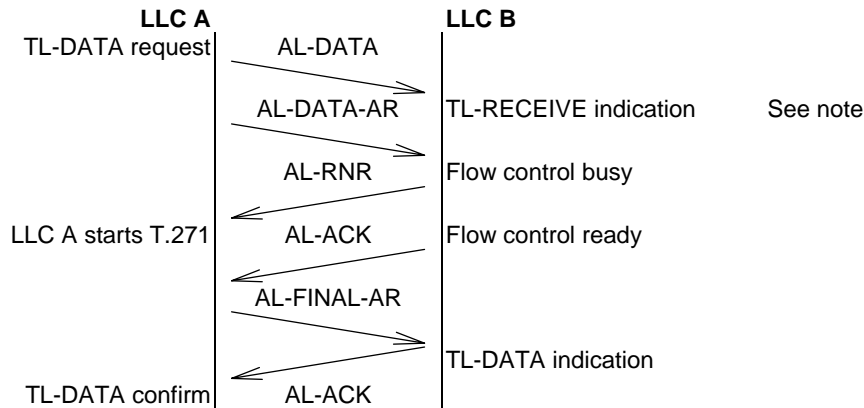

Figure 22.29: Flow control PDU exchange on the original advanced link

NOTE: LLC B refers to BS LLC entity in this figure. Exact mechanism when to send the TL-RECEIVE indication primitive is outside the scope of the present document.

**Figure 22.30: Flow control on the original advanced link**

### 22.2.2.8 Connection reset

The connection reset may be performed using connection set-up procedure, refer to clause 22.2.2.1.

#### 22.2.2.8a LLC reconnecting an advanced link (AL-RECONNECT PDU)

Prior to performing a cell handover, the LLC service user may request that an advanced link is locally disconnected by using the TL-RELEASE request primitive. However, where the MS is involved in the transmission or reception of TL-SDU segments immediately prior to cell handover, the LLC service user may decide not to disconnect the advanced link but instead may request the LLC to reconnect the advanced link on the new cell by using TL-RECONNECT request primitive, when the SwMI supports or recognizes the advanced link roaming, and thus continue the transmission or reception of TL-SDU segments from where it finished on the previous cell.

When the MS initiates an LLC reconnection, see figures 22.31 and 22.32, the timer T.265 (Reconnection waiting timer) shall be started at the TL-RECONNECT request primitive. On reception of the AL-RECONNECT PDU, and where the LLC reconnection has been successful as indicated by the reconnect report field value "success", the LLC shall send a TL-RECONNECT confirm primitive to the service user to indicate the successful result of the LLC reconnection and a TMC-CONFIGURE request primitive to the MAC in order to accept the channel change when requested, and the MS LLC may continue using the advanced link on the new cell without a reset.

NOTE: When the MS moves to a new cell, it should not send any TMA-UNITDATA request primitives containing TL-SDU segments for an advanced link until that advanced link has been successfully reconnected on the new cell (or set up again or reset).

On reception of the AL-RECONNECT PDU, and where the LLC reconnection attempt has failed as indicated by the reconnect report field value "reject", or when timer T.265 has expired N.265 times (maximum number of reconnection retries), without success, then MS LLC shall consider that the reconnection of the advanced link has failed and inform the service user by a TL-RECONNECT confirm primitive with the reconnection result set to "reject" or "failed" respectively.

If the MS is involved in the transmission or reception of TL-SDU segments on more than one advanced link immediately prior to cell handover, the LLC service user may request the LLC to reconnect some or all of the advanced links on the new cell by using multiple TL-RECONNECT request primitives. The LLC then performs the reconnection procedure for each of those advanced links.

The MS may then continue the transmission or reception of TL-SDU segments on those advanced links for which reconnection was successful from where it finished on the previous cell.

Figure 22.31: PDU exchange for LLC reconnection of the advanced link

NOTE: The AL-reconnection protocol is unsymmetrical in contrast to other LLC protocol parts.

Figure 22.32: LLC reconnection of an advanced link

22.2.2.9 Releasing an acknowledged advanced link (AL-DISC PDU)

An advanced link may be closed at any time by using the TL-DISCONNECT request primitive. Any ongoing data transfer shall be stopped immediately with the possible result of data loss, refer to figures 22.33 and 22.34. When the LLC starts a disconnection, see figure 22.34, then the timer T.263 shall be started at the TL-DISCONNECT request primitive. On a reception of AL-DISC or when timer T.263 has expired N.263 times without success, a TL-DISCONNECT confirm primitive is given to the service user. The LLC shall discontinue to use the advanced link immediately at the reception of an AL-DISC PDU.

Figure 22.33: PDU exchange for releasing the advanced link

Figure 22.34: Disconnection of an advanced link

22.2.2.10 Releasing an unacknowledged advanced link (AL-DISC PDU)

An unacknowledged advanced link is suppressed by using the disconnect primitive, refer to figures 22.35 and 22.36. The AL-DISC PDU may be repeated to increase reception probability. The further disconnection attempts for the same link are not passed to the service user. Disconnection may occur at any time and after that instance that unacknowledged link does not support unacknowledged data transfer.

**Figure 22.35: PDU exchange for releasing the unacknowledged advanced link**

NOTE: AL-DISC may be repeated.

**Figure 22.36: Disconnection of an unacknowledged advanced link**

### 22.2.3 Layer 2 signalling

In addition to basic link and advanced link signalling PDUs, the LLC may send and receive layer 2 signalling PDUs; these PDUs carry various types of general signalling information relating to layer 2 functions. The layer 2 functions may be either LLC or MAC functions. However, for the purposes of the data exchange mechanisms, the layer 2 signalling PDUs are treated as LLC PDUs.

In the present document, the layer 2 signalling PDUs are used only for MAC functions. Valid layer 2 signalling PDUs are as follows:

- the MS may send the L2-DATA-PRIORITY or L2-LINK-FEEDBACK-INFO or L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU;
- the BS may send the L2-SCHEDULE-SYNC or L2-LINK-FEEDBACK-CONTROL or L2-LINK-FEEDBACK-INFO PDU.

Where a layer 2 signalling PDU relates to a MAC function, the LLC provides the layer 2 signalling service to the MAC through the TLE-SAP. Then:

- in the case of transmission, information to be included in the layer 2 signalling PDU is passed from the MAC to the LLC using the TLE-UNITDATA request primitive; then the LLC shall format and send the layer 2 signalling PDU;
- in the case of reception, the LLC shall pass the information contained in the layer 2 signalling PDU to the MAC using the TLE-UNITDATA indication primitive.

NOTE: The sending LLC entity may issue a report or reports to the MAC on the progress of the sending of the layer 2 signalling information.

When the LLC sends or receives a layer 2 signalling PDU, it uses the data transfer service primitives offered by the MAC at the TMA-SAP.

The data transfer is shown for an L2-DATA-PRIORITY PDU in figures 22.37 and 22.38.

The information transfer service provided by the layer 2 signalling procedures is an unacknowledged service.

The sending LLC entity may repeat a layer 2 signalling PDU to increase the probability of a correct reception. The receiving LLC protocol does not suppress received duplicates. The layer 2 signalling service does not guarantee in-order delivery at the receiving entity.

Figure 22.38: L2-DATA-PRIORITY PDU sending

## 22.3 LLC procedures

### 22.3.0 General

In this clause the word "shall" is used with service primitives for traceability reasons in the protocol model, but the primitives are not testable and do not imply any implementation.

### 22.3.1 Common procedures for all services

#### 22.3.1.0 General

This clause describes protocol procedures, which are used in all LLC services or which are common to all services.

#### 22.3.1.1 Link identifiers, endpoint identifiers and handle to the request

Link identifiers between the service user (MLE) and LLC shall serve to distinguish between the multiple concurrent services, e.g. among several advanced links and their associated basic links. These identifiers may be local.

The endpoint identifiers between the MLE and LLC, and between the LLC and MAC, refer to the MAC resource that is currently used for that service. These identifiers may be local. There shall be a unique correspondence between the endpoint identifier and the physical allocation (timeslot or timeslots) used in the MAC. (This correspondence is known only within the MAC.) More than one advanced link may use one MAC resource.

Acknowledgement shall use the same endpoint identifier in the LLC.

When the LLC receives a service request primitive (except TL-RELEASE request) from the MLE, the primitive includes a local identifier for the service request, referred to as the "handle to the request". The handle should be retained locally and used for identifying subsequent related service primitives. It refers to all actions required in the LLC to accomplish the request. LLC shall also pass the handle to the request parameter to the MAC layer. In a similar way the MAC associates a handle to the request to each data request and the LLC shall use that handle to the request when it refers to that transmission.

The LLC shall generate a handle to the request for acknowledged data transfer service indication primitives (TL-DATA indication) and retain it for the corresponding response primitive (TL-DATA response).

The handle to the request shall cease to exist, when the requested or offered service is completed successfully or unsuccessfully.

### 22.3.1.2 Addressing

At the transmitting LLC entity, the LLC shall get the address in use as a parameter from the service user in the primitive types request and response and shall give it to the MAC as a parameter. At the receiving entity, the LLC shall get the address in use from the MAC and shall give it to the service user in the primitive types indication and confirm as a parameter. The LLC shall copy the same address parameters as in the corresponding TMA-UNITDATA indication primitive to the acknowledging TMA-UNITDATA request primitive.

NOTE: ITSIs and GTSIs in an MS are independent of each other and LLC services recognize addresses to allow concurrent basic or advanced link services. The present document does not describe how addresses affect to the LLC implementation.

If layer 3 response address is different to the address in TMA-UNITDATA indication primitive then the layer 3 response shall not be piggybacked on the layer 2 acknowledgement.

### 22.3.1.3 User data buffering

The sending LLC entity shall buffer TL-SDUs in order to offer re-transmission until individually marked as correctly received, or the maximum number of retransmissions is exceeded or the TL-SDU is cancelled by the service user or, in addition in the case of an advanced link, the link is either disconnected or re-set. When transmitting segmented TL-SDUs, the segmentation and the segments shall be preserved for further retransmissions until the TL-SDU is completely acknowledged or the maximum number of retransmissions is exceeded.

The LLC sub-entities shall update their part of the DATA\_IN\_BUFFER signal so often, that the MAC layer can update resource requests in time to prevent unnecessary breaks and random accesses in uplink data transfer, see clause 22.3.1.7.

The amount of data that may be buffered for transmission inside LLC layer is implementation dependent. This model deletes all not yet transmitted data in the advanced link buffers, when the advanced link is reset by a new set-up.

### 22.3.1.4 Cancelling SDU transmission

This procedure is local to the MS, but affects the data transfer over the air interface.

On the basic link the service user may cancel an ongoing transmission of a TL-SDU. On the reception of a TL-CANCEL request primitive from the service user the LLC shall delete the TL-SDU indicated by the handle to the request parameter in the TL-CANCEL request primitive, if that TL-SDU is still in the transmission buffer and no part of it is transferred to the MAC layer, and shall indicate the cancellation to the service user in a TL-REPORT indication primitive (aborted, TL-SDU not completely sent). Otherwise LLC shall forward cancellation request to the MAC as a TMA-CANCEL request primitive. If the corresponding MAC TMA-REPORT indication primitive (aborted, TM-SDU not completely sent) shows that the MAC has aborted the transmission and the TM-SDU has not been completely sent, then the LLC shall delete the corresponding TL-SDU from the sending buffer and shall indicate the cancellation to the service user in a TL-REPORT indication primitive (aborted, TL-SDU not completely sent). If the MAC has sent the whole SDU containing the TL-SDU for which a cancellation was requested, then the MAC will indicate with a TMA-REPORT indication primitive (aborted, TM-SDU sent at least once) that the whole TL-SDU is sent. The LLC shall then delete the corresponding TL-SDU from the sending buffer and indicate in a TL-REPORT indication primitive (aborted, TL-SDU sent at least once) to the service user that the DLL has aborted sending actions but the TL-SDU has been sent at least once.

NOTE 1: If the LLC has transferred the SDU to the MAC more than once, then it is the LLC's responsibility to issue the correct TL-REPORT indication primitive to the higher layers, taking into account also the results of the previous transmission attempts.

In the advanced link the DLL can cancel the transmission of the TL-SDU only if the first segment has not been sent at all. On the reception of a TL-CANCEL request primitive from the service user the LLC shall delete from the transmission buffer a TL-SDU, if sending has not started, and indicate in a TL-REPORT indication primitive that cancellation is completed and the TL-SDU is not sent. If the LLC has delivered only the first segment of the TL-SDU to the MAC and that segment is not yet acknowledged, then the LLC shall forward cancellation request to the MAC as a TMA-CANCEL request primitive. If the corresponding MAC TMA-REPORT indication primitive shows that the MAC has aborted the transmission and the TM-SDU corresponding to the first segment has not been sent at all, then the LLC shall delete the corresponding TL-SDU from the sending buffer and shall indicate the successful cancellation (the TL-SDU is not completely sent) to the service user in a TL-REPORT indication primitive.

If the TMA-REPORT indication primitive shows that the MAC has sent the TM-SDU corresponding to the first segment at least once, then the LLC shall indicate with a TL-REPORT indication primitive (layer two transmission activities continuing) and continue TL-SDU transmission.

NOTE 2: If the LLC has delivered the first segment of the TL-SDU to the MAC and that segment is not yet acknowledged, and the LLC has also delivered further segments of the TL-SDU to the MAC to be sent in the same MAC block as the first segment, the LLC may attempt cancellation of all those segments. If the corresponding MAC TMA-REPORT indication primitives show that the MAC has aborted the transmission of all the segments, the LLC may regard the cancellation as successful; whereas, if the MAC TMA-REPORT indication primitives show that the MAC has sent the TM-SDU corresponding to any of the segments of the TL-SDU, the LLC indicates to the service user that layer two transmission activities are continuing and continues the TL-SDU transmission.

NOTE 3: The above applies to an MS. A BS LLC sending TL-SDUs on an unacknowledged advanced link may stop transmission of a particular TL-SDU at any time without disconnecting or resetting that unacknowledged advanced link.

The advanced link service user may also stop transmission of a TL-SDU by disconnecting or resetting by a new set-up the corresponding advanced link, refer to clauses 22.3.3.3 and 22.3.3.1.

NOTE 4: The DLL always responds to a TL-CANCEL request primitive with a TL-REPORT indication primitive.

### 22.3.1.5 Extended error protection

An extended error detection (FCS) shall be offered as a selectable part of the service on the basic link or an extended advanced link and as a mandatory part of the service on the original advanced link. When appropriate the sending LLC shall calculate over the TL-SDU a FCS and shall append it to the TL-SDU.

When a FCS is appended to the TL-SDU, then the receiving LLC entity shall test the received TL-SDU against the FCS to detect whether errors have been introduced into the TL-SDU during transmission. When the receiving LLC detects errors in the received TL-SDU, the LLC shall not pass the erroneous TL-SDU to the service user, but instead the LLC shall discard the erroneous TL-SDU and enforce an SDU re-transmission if appropriate.

The FCS is defined in annex C.

### 22.3.1.6 Timers and counters

In the protocol description, timers and counters are referred to either by their names or by their value symbols or both e.g. set-up waiting timer T.261. Stopping of timers and counter re-settings are shown only when implicit reasons are not obvious. This protocol does not define or restrict any implementation of timers or counters.

Some of the LLC timers are defined in terms of downlink signalling frames for the channel on which the downlink message is expected (see annex A). If the MS supports the napping procedure (see clause 23.4.8), the LLC shall inform the MAC whether any of those timers are currently running, using the TMC-CONFIGURE request primitive. The LLC timers that are defined in downlink signalling frames are timers T.251, T.252, T.261, T.263 and T.265.

### 22.3.1.7 Formatter protocol

#### 22.3.1.7.0 General

The sending formatter controls the transmission order of the LLC PDUs. It delivers LLC PDUs to the MAC conceivably according to the optional priority order of the PDUs using TMA-UNITDATA request primitives. The receiving formatter identifies LLC PDU headers in the MAC TMA-UNITDATA indication primitives and delivers the PDUs to the corresponding LLC entities.

NOTE: PDU priority is considered as an optional feature and it applies to all LLC data sending entities.

### 22.3.1.7.1 MS formatter receiving entity

Upon reception of a TMA-UNITDATA indication primitive the formatter shall decode the PDU type (and supplementary PDU subtype when appropriate). The formatter shall route the corresponding PDU according to the PDU type, endpoint identifier and address (and supplementary PDU subtype and advanced link number when appropriate) to the appropriate LLC protocol sub-entity instance. If the formatter recognizes a PDU which is not valid for the current composition of LLC entities, then the formatter shall discard the PDU without any further actions.

### 22.3.1.7.2 MS formatter sending entity

The LLC shall indicate to the MAC the availability of data to be transmitted with the DATA\_IN\_BUFFER signal, which specifies:

- the total amount of all outstanding data of all LLC sub-entities (including pending acknowledgements) that the LLC has ready to send with the specified address on the channel corresponding to the specified endpoint identifier;
- the highest stealing permission for that data;
- the highest PDU priority for outstanding unscheduled data that the LLC has ready to send with the specified address on the channel corresponding to the specified endpoint identifier;
- if the MS is on a D8PSK or QAM channel: the subdivision into data categories of the outstanding data that the LLC has ready to send with the specified address on the channel corresponding to the specified endpoint identifier;
- if the MS supports data priority:
  - the maximum data priority for the outstanding data to be sent with the specified address on the channel corresponding to the specified endpoint identifier;
  - a parameter indicating whether or not the next PDU expected to be sent with the specified address on the channel corresponding to the specified endpoint identifier contains packet data;
  - if the MS is on a  $\pi/4$ -DQPSK channel: the subdivision into data priorities of the outstanding data to be sent with the specified address on the channel corresponding to the specified endpoint identifier;
  - if the MS is on a D8PSK or QAM channel: the subdivision into data categories and data priorities of the outstanding data to be sent with the specified address on the channel corresponding to the specified endpoint identifier;
- a parameter indicating whether all, some or none of the outstanding data that the LLC has ready to send with the specified address on the channel corresponding to the specified endpoint identifier is fully scheduled, and the lowest value of the maximum schedule interval for any outstanding fully scheduled data; and
- the highest PDU priority for outstanding fully scheduled data that the LLC has ready to send with the specified address on the channel corresponding to the specified endpoint identifier.

NOTE: When indicating the maximum data priority and the amount of outstanding data for each data priority, the LLC may include all data in its queue for the specified address and endpoint identifier (including data that is not yet ready to be sent).

In the case of an emergency message the formatter should deliver the corresponding DATA\_IN\_BUFFER signal to the MAC before a possible TMA-CANCEL request primitive so that MAC could make a new reservation request during the cancel process.

Upon reception of MAC-READY from the MAC, the LLC shall decide which of the outstanding PDUs have to be sent, depending on the protocol needs and the size of the next MAC block. Within the same service, acknowledgements shall be sent prior to any data PDUs. Acknowledged basic link PDUs shall be sent before unacknowledged basic link and advanced link PDUs (subject to the window size of 1 for the acknowledged basic link) unless the PDU priority of the unacknowledged basic link or advanced link PDUs is higher than the PDU priority of the acknowledged basic link PDUs. Layer 2 signalling PDUs shall be sent before basic link and advanced link PDUs unless the PDU priority of the basic link or advanced link PDUs is higher than the PDU priority of the layer 2 signalling PDUs. L2-DATA-PRIORITY PDUs shall be sent before other layer 2 signalling PDUs.

The LLC shall deliver the PDU to the MAC using a TMA-UNITDATA request primitive containing the handle to the request parameter from the corresponding TL-service primitive for further referencing; in the case of a layer 2 signalling PDU, the LLC shall include a handle to the request parameter for further referencing.

There may be multiple MAC-READY and TMA-UNITDATA request exchanges, if the MAC is performing an association of LLC PDUs into one MAC block.

If the MS is on a D8PSK channel, the first MAC-READY signal indicates the available size of the MAC block for each data category. (For example, advanced link segments may be of different size, depending on whether the MAC considers that  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation would currently be appropriate for first transmissions of segments for this data category.) Any further MAC-READY signals for a MAC block also indicate any restrictions on the data categories for which an LLC PDU may be sent as the second or subsequent PDU in the MAC block; the LLC should use this information as an additional criterion when deciding which of the outstanding PDUs to send.

If the MS is on a QAM channel, the MAC-READY signal indicates the normal advanced link segment size. After the first MAC-READY signal, any further MAC-READY signals for a MAC block also indicate any restrictions on the data categories for which a normal data segment or other LLC PDU may be sent as the second or subsequent PDU in the MAC block. (In the case of a MAC block in a subslot, the first MAC-READY signal also indicates any restrictions on the data categories for which a normal advanced link data segment may be sent as the first PDU in the MAC block.) The LLC should use this information as an additional criterion when deciding which of the outstanding PDUs to send.

The MAC will select the relevant means to transfer the information, i.e. either by random or reserved access or frame stealing, as appropriate based on the selected PDU priority and stealing permission parameter.

If the MS is on a D8PSK or QAM channel, the MAC will also select the appropriate modulation level (and coding rate for QAM) to use for reserved access, based on the data category indicated in the TMA-UNITDATA request primitive(s).

### 22.3.1.7.3 Combination PDUs on D8PSK or QAM channel

#### 22.3.1.7.3.0 General

Three LLC PDUs are defined with combined functions:

- on a D8PSK or QAM channel, AL-X-ACK and AL-X-RNR PDUs sent by both the MS and BS may optionally include link adaptation feedback information in addition to the usual acknowledgement information;
- on a D8PSK or QAM channel, the L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU may be used for the MS to send link adaptation feedback information and residual data priority within a single PDU.

According to the protocol model, the combining for sending is performed by the LLC upon reception of the MAC-READY signal from the MAC; the separation on reception is performed by the formatter receiving entity.

NOTE: This does not imply any specific implementation. In an implementation, the combining and/or separation may be performed using other equivalent methods.

#### 22.3.1.7.3.1 MS formatter receiving entity for combination PDUs

Upon reception of a TMA-UNITDATA indication primitive, the formatter shall decode the PDU type (and supplementary PDU subtype when appropriate) - as defined in clause 22.3.1.7.1. If the PDU is an AL-X-ACK or AL-X-RNR PDU and the link feedback information flag is set to 1, the formatter shall construct an L2-LINK-FEEDBACK-INFO PDU from the "link feedback information" information element. It shall then route each PDU (AL-X-ACK or AL-X-RNR and L2-LINK-FEEDBACK-INFO) to the appropriate LLC protocol sub-entity instance for that PDU.

### 22.3.1.7.3.2 MS formatter sending entity for combination PDUs

Upon reception of MAC-READY from the MAC, the LLC shall decide which of the outstanding PDUs have to be sent, depending on the protocol needs and the size of the next MAC block - as defined in clause 22.3.1.7.2. The LLC may then check whether combining of PDUs is appropriate as follows:

- a) If the PDU to be sent is an L2-LINK-FEEDBACK-INFO PDU, the LLC may look through the outstanding PDUs for that endpoint identifier and address. If the LLC finds an AL-X-ACK or AL-X-RNR PDU, and assesses that a combined PDU could be sent in the MAC block without the combining causing fragmentation, it may construct and send a combined PDU i.e. an AL-X-ACK or AL-X-RNR PDU with the link feedback information flag set to 1 and with the link feedback information from the L2-LINK-FEEDBACK-INFO PDU included in the "link feedback information" information element.
- b) If the PDU to be sent is an AL-X-ACK or AL-X-RNR PDU, the LLC may look through the outstanding PDUs for that endpoint identifier and address. If the LLC finds an L2-LINK-FEEDBACK-INFO PDU, and assesses that a combined PDU could be sent in the MAC block without the combining causing fragmentation, it may construct and send a combined PDU i.e. an AL-X-ACK or AL-X-RNR PDU with the link feedback information flag set to 1 and with the link feedback information from the L2-LINK-FEEDBACK-INFO PDU included in the "link feedback information" information element.
- c) If the PDU to be sent is an L2-DATA-PRIORITY PDU containing no data priority blocks, the LLC may look through the outstanding PDUs for that endpoint identifier and address. If the LLC finds an L2-LINK-FEEDBACK-INFO PDU, and assesses that a combined PDU could be sent in the MAC block without the combining causing fragmentation, it may construct and send a combined PDU i.e. an L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU.

The LLC shall deliver the combined PDU to the MAC using a TMA-UNITDATA request primitive containing an appropriate handle for further referencing (and using the higher of the two PDU priorities if they are different). On receipt of a TMA-REPORT indication primitive for that handle, the formatter shall generate two TMA-REPORT indication primitives containing the same "Report" parameter - one for each of the original PDUs.

**EXAMPLE:** For example, in case c), on receipt of a TMA-REPORT indication primitive indicating successful complete transmission by random access, the formatter generates a TMA-REPORT indication primitive indicating successful complete transmission by random access for each of the constituent PDUs. Then, as defined in clause 22.3.7.1, the LLC generates equivalent TLE-REPORT indication primitives to the MAC independently for each of the PDUs.

## 22.3.1.8 Data priority

### 22.3.1.8.0 Introduction

Clauses 22.3.1.8.1, 22.3.1.8.2, 22.3.1.8.3 and 22.3.1.8.4 shall be applicable only to MSs which support data priority.

#### 22.3.1.8.1 General

Data priority enables the MS to indicate a priority for obtaining reserved slots when it is sending packet data. For example, this permits the BS to grant slots to an MS with high data-priority PDUs to send ahead of other MSs with lower data-priority PDUs to send on the same channel.

**NOTE:** Data priority is distinct from PDU priority. PDU priority affects the MS's queue re-ordering in the LLC and the MS's random access procedure. Data priority principally affects the BS's criteria for slot granting on a shared packet data channel, but is also used for queue re-ordering in the LLC.

The SNDCP in an MS that uses data priority either regards the "MS default data priority" as being the "network default data priority" indicated by the SwMI or may negotiate a specific MS default data priority with the SwMI (see clause 28.3.5.5). In either case, the MS default data priority is a data priority which the BS applies by default to all reservation requirements indicated by that MS on a packet data channel.

Also, when the SNDCP sends each packet data PDU, it includes the data priority for that PDU within the primitive issued to the lower layers; the data priority parameter is set to one of the eight defined values of data priority (0 to 7) for data that is not scheduled or contains the value "undefined" in the case of scheduled data. This information enables the DLL in the MS to request short-term variations to the default data priority:

- the LLC collates the information on data priorities for TL-SDUs and LLC PDUs, and issues it to the MAC in the DATA\_IN\_BUFFER signal;
- when appropriate, the MAC sends an L2-DATA-PRIORITY message if it wishes to indicate a short-term variation to the default data priority - either indicating a single short-term data priority or indicating the current requirements for multiple data priorities (see clause 23.4.7); the L2-DATA-PRIORITY message is a layer 2 signalling message, so the MAC issues it to the LLC in a TLE-UNITDATA request primitive;
- the LLC sends the message using the procedures defined in clause 22.3.7.1.

The LLC also indicates to the MAC whether it currently expects that the next PDU to be sent will contain packet data. (This may affect the MAC criteria for initiating the random access procedure.)

### 22.3.1.8.2 Sending order of TL-SDUs

Packet data TL-SDUs to be sent on a channel are sent using the unacknowledged basic link for that channel or using an advanced link. The data priority of each packet data TL-SDU is indicated by the service user in the TL-DATA request primitive for an advanced link and in the TL-UNITDATA request primitive for the basic link (except in the case of scheduled data).

If the MS supports data priority, and the MS default data priority last provided by the higher layers in the TL-CONFIGURE request primitive contained one of the eight defined values (i.e. was not set to "not applicable"), then the LLC shall modify the sending order of packet data TL-SDUs to be sent on a channel (using the unacknowledged basic link or any advanced link) as follows:

- the LLC shall order the packet data TL-SDUs according to the PDU priority;
- the LLC shall order the packet data TL-SDUs within one PDU priority according to the data priority.

It is recommended that, within one PDU priority and data priority, the LLC sends unacknowledged basic link packet data TL-SDUs before advanced link packet data TL-SDUs.

When the higher layers issue scheduled data to the LLC (see clause 22.3.1.9), the data priority parameter in the TL-DATA or TL-UNITDATA request primitive is set to "undefined". The data priority parameter may have a defined value for initial scheduled data. For the purposes of the ordering of packet data TL-SDUs, the LLC should:

- regard scheduled data TL-SDUs as having data priority higher than 6 i.e. as having a data priority equivalent to "6,5";
- regard initial scheduled data TL-SDUs with "undefined" data priority as having data priority "6,5";
- regard initial scheduled data TL-SDUs with a defined data priority as having data priority equal to the maximum of "6,5" and the defined data priority.

NOTE 1: The definition of assumed data priority of "6,5" for scheduled data and initial scheduled data in these three points applies only for the purposes of LLC ordering of packet data TL-SDUs. It is not used when collating data priority information to provide to the MAC (see clause 22.3.1.8.3); the value of the data priority parameter in the TL-DATA or TL-UNITDATA request primitive (i.e. value "undefined" for scheduled data) applies in clause 22.3.1.8.3.

If already-started TL-SDUs being sent on an advanced link have lower PDU priority or data priority than an unstarted TL-SDU to be sent on that advanced link then, for the purposes of the ordering of packet data TL-SDUs, the LLC should promote those already-started TL-SDU(s) as follows:

- if already-started TL-SDU(s) being sent on an advanced link have lower PDU priority than an unstarted TL-SDU to be sent on that advanced link then, for the purposes of the ordering of packet data TL-SDUs, the LLC should promote those already-started TL-SDU(s) to the higher PDU priority; and

- if already-started TL-SDU(s) being sent on an advanced link have lower data priority, and have the same or lower PDU priority, than an unstarted TL-SDU to be sent on that advanced link then, for the purposes of the ordering of packet data TL-SDUs, the LLC should promote those already-started TL-SDU(s) to the higher data priority.

NOTE 2: Thus already-started and unstarted TL-SDUs for an advanced link with high maximum priority are sent before already-started (and unstarted) TL-SDUs for other advanced links with lower maximum priority; they are also sent before unacknowledged basic link packet data with lower maximum priority.

NOTE 3: The LLC may vary the sending order of TL-SDUs from the order defined above if there are temporary constraints on which TL-SDUs may be sent, for example, if the window of an advanced link is full or, on a D8PSK or QAM channel, if there are restrictions on the data categories for which an LLC PDU may be sent as the second or subsequent PDU in a MAC block.

NOTE 4: The LLC may choose not to fill up the advanced link sending window or may restrict the amount of data in the sending window if it expects that the higher layers may wish to send higher priority PDUs than those currently in the window. The criteria that the LLC uses to decide whether to restrict the number of TL-SDUs in the advanced link sending window are outside the scope of the present document.

There are other types of TL-SDUs and LLC PDUs that may need to be sent on the channel:

- TL-SDUs to be sent using the acknowledged basic link;
- TL-SDUs that do not contain packet data, and are to be sent using the unacknowledged basic link or an advanced link;
- AL-SETUP, AL-RECONNECT and AL-DISC PDUs;
- layer 2 signalling PDUs; and
- basic link and advanced link acknowledgements.

These TL-SDUs and LLC PDUs have a PDU priority but do not have a data priority. The LLC should choose an appropriate ordering, subject to the constraints given in clause 22.3.1.7.2.

EXAMPLE: In cases a), b), c) and d), the TL-SDU or LLC PDU may be sent ahead of packet data irrespective of the PDU priority, or may be included in the packet data ordering per PDU priority (ahead of the packet data with that PDU priority).  
In case e), clause 22.3.1.7.2 requires that, within the same service, acknowledgements are sent prior to any data PDUs.

NOTE 5: In cases a), b), c) and d), it is recommended that TL-SDUs and LLC PDUs with PDU priority 2 or more are at least sent ahead of packet data with PDU priority 6; they may be sent ahead of packet data with PDU priority 7. Also TL-SDUs and LLC PDUs with PDU priority 0 or 1 may be sent ahead of packet data irrespective of PDU priority.

### 22.3.1.8.3 Providing data priority information to the MAC

If the MS supports data priority then, as described in clause 22.3.1.7.2, the DATA\_IN\_BUFFER signal shall indicate the maximum data priority for the outstanding data to be sent with the specified address on the channel corresponding to the specified endpoint identifier, and the subdivision of that outstanding data into data priorities (and data categories if the MS is on a D8PSK or QAM channel).

NOTE 1: When indicating the maximum data priority and the amount of outstanding data for each data priority, the LLC may include all data in its queue for the specified address and channel (including data that is not yet ready to be sent).

The LLC shall generate the information as follows.

The data priority of each TL-SDU is generally indicated by the service user in the TL-DATA request primitive for the advanced link and in the TL-UNITDATA request primitive for the basic link; in some cases the data priority parameter may contain the value "undefined" (for example, for scheduled data). In the case of a TL-DATA request primitive for the advanced link, the LLC shall regard the specified data priority as applying to the first transmission of segments of the TL-SDU and to any segment re-transmissions. In the case of a TL-UNITDATA request primitive for the basic link, the LLC shall regard the specified data priority as applying to all  $N.253 + 1$  transmissions of the TL-SDU.

The LLC shall regard TL-SDUs to be sent on the acknowledged basic link as having "undefined" data priority. It shall also regard PDUs not containing a TL-SDU or TL-SDU segment as having "undefined" data priority (e.g. LLC acknowledgements, AL-SETUP, AL-RECONNECT, AL-DISC and layer 2 signalling PDUs).

If the LLC queue for an address and channel contains TL-SDUs with different defined data priorities or a mixture of defined data priorities and "undefined" data priority, the LLC should modify the data priorities as follows - after any re-ordering of the sending order of TL-SDUs and LLC PDUs. When a TL-SDU with defined data priority DPRI (denoted TL-SDU<sub>N</sub>) is in the LLC queue (either already started or waiting to be sent):

- any data with lower data priority and preceding TL-SDU<sub>N</sub> in the LLC queue for that address and channel (either already started or waiting to be sent) should be promoted to data priority DPRI;
- any data with undefined data priority and preceding TL-SDU<sub>N</sub> in the LLC queue for that address and channel (either already started or waiting to be sent) should be promoted to data priority DPRI, except that any L2-DATA-PRIORITY PDU should retain data priority value "undefined".

Any data with undefined data priority, not preceding data with defined data priority, should retain data priority value "undefined". In particular, if there is no data with defined data priority in the LLC queue, then all data in the LLC queue retains data priority value "undefined" and the LLC shall set the maximum data priority parameter in the DATA\_IN\_BUFFER signal to "undefined".

NOTE 2: In an implementation, this process may be performed by initializing a "maximum data priority encountered so far" parameter to a null value of "undefined" and working forwards, keeping a record of the maximum data priority encountered so far (where any defined data priority is regarded as higher than the undefined data priority for the purposes of this process). Any data with undefined data priority (except the L2-DATA-PRIORITY PDU), or with lower data priority than the maximum data priority encountered so far, is promoted to the maximum data priority encountered so far.

After performing this process, if a TL-SDU that does not contain packet data has PDU priority 7 and has data priority less than 7, the LLC may promote that TL-SDU to data priority 7.

The LLC shall then collate the resulting modified data priority information and pass it to the MAC in the DATA\_IN\_BUFFER signal.

The LLC shall also indicate to the MAC (using the DATA\_IN\_BUFFER signal) whether or not it currently expects that the next PDU to be sent with the specified address on the channel corresponding to the specified endpoint identifier will contain packet data.

#### 22.3.1.8.4 Sending of L2-DATA-PRIORITY PDU

When the LLC receives a TLE-UNITDATA request primitive from the MAC requesting sending of an L2-DATA-PRIORITY PDU, the LLC shall send the PDU using the procedures defined in clause 22.3.7.1.

When the MAC issues the TLE-UNITDATA request primitive, it sets the PDU priority to the highest PDU priority indicated in the DATA\_IN\_BUFFER signal (see clause 23.4.7) so that, on reception of the next MAC-READY signal, the LLC will normally send the L2-DATA-PRIORITY PDU (issuing the PDU to the MAC using a TMA-UNITDATA request primitive).

#### 22.3.1.9 Scheduled data

When the LLC in an MS receives a TL-DATA request primitive for the advanced link, or a TL-UNITDATA request primitive for the basic link, the "scheduled data status" parameter in the primitive indicates whether the TL-SDU should be treated as:

- not scheduled data (i.e. if the data is not for a schedule); or
- initial scheduled data (i.e. for the first TL-SDU of a schedule or after a substantial gap in use of the schedule);  
or
- scheduled data (i.e. for subsequent TL-SDUs of a schedule).

See also clause 28. For scheduled data, the primitive also indicates the maximum schedule interval for this schedule.

As described in clause 22.3.1.7.2, the DATA\_IN\_BUFFER signal from the LLC to the MAC indicates whether all, some or none of the outstanding data for the specified address and channel is "fully scheduled", and the lowest value of the maximum schedule interval for any outstanding "fully scheduled" data; it also indicates the maximum PDU priority for outstanding "unscheduled" and "fully scheduled" data. When generating this information, the LLC shall convert from the information in the "scheduled data status" parameter to the information about "fully scheduled" and "unscheduled" data in the buffer as follows:

- in the case of initial scheduled data sent by acknowledged transfer on an advanced link, the LLC shall regard the first transmission of the TL-SDU and any segment re-transmissions as unscheduled;
- in the case of initial scheduled data sent by unacknowledged data transfer on the basic link, the LLC shall regard all  $N.253 + 1$  transmissions of the TL-SDU as unscheduled;
- in the case of scheduled data sent by acknowledged transfer on an advanced link, the LLC shall regard the first transmission of the TL-SDU as fully scheduled and should regard any segment re-transmissions as unscheduled;
- in the case of scheduled data sent by unacknowledged data transfer on the basic link, the LLC shall regard all  $N.253 + 1$  transmissions of the TL-SDU as fully scheduled;
- the LLC shall regard all other types of data and signalling as unscheduled.

NOTE: The MAC uses the information about "fully scheduled" and "unscheduled" data in the buffer to decide when to initiate the random access procedure.

### 22.3.1.10 Data category

When on a D8PSK or QAM channel, the MAC selects the appropriate modulation level (and coding rate for QAM) to use when sending TM-SDUs by reserved access, based on the link conditions and the data category parameter in the TMA-UNITDATA request primitive(s); see clause 23.4.9.

The data category parameter is provided by the LLC in the TMA-UNITDATA request primitive (partly derived from the data class information parameter from the higher layers). It may be used to indicate information about the type of data in the TM-SDU and the required reliability level for the transmission - enabling the MAC to make decisions about the modulation level (and coding rate for QAM) to use when sending the TM-SDU. The implementer should choose an appropriate definition of the data category parameter for the chosen link adaptation algorithm.

For example, the data category parameter may indicate whether the data in the TM-SDU is:

- background class data - reliability level 1; or
- background class data - reliability level 2; or
- background class data - reliability level 3; or
- telemetry class data - reliability level 1; or
- telemetry class data - reliability level 2; or
- telemetry class data - reliability level 3; or
- real-time class data; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 1; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 2; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 3.

NOTE 1: In this example of possible data categories, it is intended that reliability level 3 refers to better (i.e. higher) reliability than reliability level 2, and reliability level 2 refers to better (i.e. higher) reliability than reliability level 1.

NOTE 2: In this example of possible data categories, three reliability levels are used for background class data, telemetry class data and non-classified data. In an implementation, fewer than three reliability levels could be used if preferred. For instance, if preferred, two reliability levels could be used for background class data and/or telemetry class data and/or non-classified data.

NOTE 3: The MAC uses both the data class and the reliability level when it selects the appropriate modulation level (and coding rate for QAM). For example, the appropriate modulation level (and/or coding rate for QAM) for "telemetry class data - reliability level 1" may be different from that for "background class data - reliability level 1".

When indicating the required reliability level for the transmission, it is recommended that:

- a) TL-SDUs sent by acknowledged data transfer on the basic link should be sent using a high reliability for all transmissions (except possibly the first transmission(s) of short data messages).
- b) Basic link acknowledgements should be sent using a high reliability for all transmissions.
- c) AL-SETUP, AL-RECONNECT and AL-DISC PDUs should be sent using a high reliability for all transmissions.
- d) Advanced link acknowledgements (AL-ACK, AL-RNR, AL-X-ACK and AL-X-RNR) should be sent using a high reliability for all transmissions.

NOTE 4: Thus, in the example of possible data categories, items a), b), c) and d) could be sent using "non-classified data - reliability level 3" for all transmissions (except possibly the first transmission(s) of short data messages).

NOTE 5: The recommendation to use a high reliability for all transmissions for items a), b), c) and d) does not necessarily mean use of 4-QAM coding rate = 1/2 for all transmissions on a QAM channel when the current channel conditions are perceived as very good, for example, if low slot error rates are currently expected for 16-QAM coding rate = 1/2 (see also clause 23.4.9.2.1).

- e) Layer 2 signalling PDUs sent on request of the MAC should be sent using the data category indicated by the MAC in the TLE-UNITDATA request primitive.

NOTE 6: In the example of possible data categories, when the MAC issues the TLE-UNITDATA request primitive, it could indicate non-classified data with either reliability level 1, 2 or 3 depending on the required reliability of the information in the layer 2 signalling message. For example, reliability level 1 could be used when the layer 2 signalling message may be sent using the same modulation level and coding rate as any ongoing packet data, whereas reliability levels 2 and 3 could indicate a requirement for higher reliability.

- f) When a segment has been sent a number of times on an acknowledged advanced link, further retransmissions of that segment should be sent using a higher reliability. So, for example, for background class data or telemetry class data, if using three reliability levels, the MS (or BS) could use reliability level 1 for the first one or more transmissions of advanced link segments (enabling higher throughput when successful), then use reliability level 2 for the next one or more retransmissions of segments (if retransmissions are needed) and then revert to reliability level 3 for a segment either:
  - when the segment has been sent a specific number of times without success; and/or
  - when only a specific number of retransmissions remain before the maximum number of segment retransmissions N.274 of that segment is exceeded.

At least the last two possible retransmissions of a segment before the maximum number of segment retransmissions N.274 of that segment is exceeded should be sent using a high reliability.

NOTE 7: In the example of possible data categories, the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may depend on the maximum number of segment retransmissions  $N_{274}$  for that advanced link.

In an implementation, the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may also vary according to the current channel conditions, based on information provided to the LLC by the MAC.

When appropriate, the MS (or BS) may revert to using fewer than three reliability levels.

NOTE 8: As indicated in point f), it is expected that, for acknowledged packet data, the reliability level may vary for transmissions of one segment according to the number of times that segment has been transmitted, starting with low reliability and increasing to higher reliability if the first transmission(s) of that segment are not successful. This contrasts with non-classified data (items a) to e)) for which the type of information may determine the reliability level for all transmissions of that PDU (except possibly for short data messages).

## 22.3.2 Basic link procedures

### 22.3.2.0 General

The basic link shall offer two services, acknowledged and unacknowledged data transfer. The acknowledged service supports also a data response service primitive for call set-up optimization. The data with the response primitive is transmitted using an acknowledge message without an explicit acknowledgement, see clause 22.2.1.1.

The basic link LLC protocol of the MS is modelled by two processes, `BL_LLC_MS` and `Formatter`, the latter being common with the advanced links and layer 2 signalling, refer to figure 22.2.

The present document models the numbering of TL-SDUs and acknowledgements and local function indicators by local variables. Each basic link shall employ separate sets of variables, parameters and timers. At the sending side variables and main parameters are:

- `N(S)` TL-SDU number in the sent data PDUs;
- `N(R)` TL-SDU number in the received acknowledgement PDUs;
- `V(S)` the next TL-SDU number to be sent or to be re-sent;

and at the receiving side:

- `N(S)` TL-SDU number in the received data PDUs;
- `N(R)` TL-SDU number in the sent acknowledgement PDUs;
- `V(R)` the last received TL-SDU number.

Timers and constants are defined in annex A.

NOTE: This protocol description is valid for one basic link, which uses one address.

### 22.3.2.1 Establishment of information transfer in basic link

No explicit establishment is required for the basic link. At least one basic link shall be available when the MS is synchronized to a BS. When there is no advanced link nor circuit mode connection, then there is a single basic link on the corresponding control channel. When there are any defined advanced links or circuit mode connections, then there is one basic link per each advanced link and circuit mode connection. If an advanced link uses the same physical resource allocations as a circuit mode connection, then there is only one basic link associated with the pair. If multiple advanced links use the same physical resource, then there is only one basic link associated with those multiple advanced links.

The MS shall keep all basic links that are not removed in the physical resource allocation, if the MS is capable of operation on concurrent channels, see clause 23. The BS may allocate e.g. the first advanced link and the basic link associated to a circuit mode call so that the previous basic link on the initiating control channel is released.

After power-on or in the first transmission, when roaming or migrating to a new BS, the MS LLC shall start TL-SDU numbering from "0" by setting local variable  $V(S) = 0$ .

### 22.3.2.2 Quality of service selection

The service user shall define the quality of service for each message by selecting a basic link and the primitive type either TL-DATA request or TL-UNITDATA request and by selecting the parameters in that primitive, see definition of parameters in clause 20. The undetected message error rate shall be defined by selecting the use of the FCS. The TL-SDU sending order in the selected basic link and in relation to any concurrent advanced link(s) and layer 2 signalling shall be defined by the conceivably requested PDU priority, which may change the transmission order of TL-SDUs. The PDU priority shall affect the transmission of a already started TL-SDU sending only if the highest priority (emergency) is used and the sending of the current TL-SDU is destroyed by cancellation.

NOTE: The maximum data transfer throughput of an associated basic link is defined by the associated advanced link(s) or circuit mode call.

### 22.3.2.3 Acknowledged data transmission in basic link

The acknowledged data transmission is modelled by the states in the sending process:

- TX\_READY transmitter is ready to send next TL-SDU;

and in the receiving process:

- RX\_READY receiver is ready to receive data from the MAC.

Each acknowledged information transfer is identified by a TL-SDU number  $N(S)$  both in BL-DATA and BL-ADATA PDUs. The acknowledgement contains the number  $N(R)$  of the correctly received TL-SDU both in BL-ACK and BL-ADATA PDUs. In addition, the receiver has the possibility to send data in a TL-DATA response primitive together with the acknowledgement without a sequence number. The  $N(R)$  in that acknowledgement marks the TL-SDU sent using an acknowledgement BL-ACK PDU.

The LLC process may receive:

- service user service primitive:
  - a) a TL-DATA request primitive (handle to the request) and then the LLC shall:
    - i) issue an immediate TL-REPORT indication primitive confirming the handle to the request parameter;
    - ii) calculate FCS, when requested, and append it to TL-SDU;
    - iii) place the TL-SDU into transmission buffer according to the indicated PDU priority;
    - iv) indicate new data in the transmitting buffer to the formatter using DATA\_IN\_BUFFER signal;
    - v) in the case of a TL-DATA request primitive with the emergency priority and if there is an ongoing lower priority TL-DATA (or TL-UNITDATA) PDU in transmission on that basic link at the MAC layer, then the LLC may deliver a TMA-CANCEL request primitive via formatter to the MAC, see clause 22.3.1.4. The LLC shall not cancel a BL-ACK PDU with or without service user data. The LLC may cancel a BL-ADATA PDU and memorize the  $N(R)$  in it.
  - b) a TL-DATA response primitive to the TL-DATA indication primitive (handle to the request) before the corresponding acknowledgement is sent and then the LLC shall:
    - i) calculate FCS, when requested, and append it to TL-SDU;
    - ii) format a BL-ACK PDU ( $N(R) = V(R)$ ) with the (optional) TL-SDU from the TL-DATA response primitive;
    - iii) inform the formatter using DATA\_IN\_BUFFER signal.

- c) a TL-DATA response primitive (handle to the request) after sending the corresponding BL-ACK or BL-ADATA PDU, then the LLC shall:
  - i) issue an immediate TL-REPORT indication primitive confirming the handle to the request parameter (from the TL-DATA response primitive) as if it has received a TL-DATA request primitive;
  - ii) calculate FCS, when requested, and append it to TL-SDU;
  - iii) place the TL-SDU into transmission buffer according to the indicated PDU priority;
  - iv) indicate new data in the transmitting buffer to the formatter using DATA\_IN\_BUFFER signal;
  - v) in the case of a TL-DATA response primitive with emergency priority and if there is an ongoing lower priority TL-DATA (or TL-UNITDATA) PDU in transmission on that basic link at the MAC layer, then the LLC may deliver a TMA-CANCEL primitive via formatter to the MAC, see clause 22.3.1.4. The LLC shall not cancel a BL-ACK PDU (which in this situation should be without user data).
- local indications:
  - d) a MAC-READY indication from the formatter and then:
    - if a BL-ACK PDU is ready due to a TL-DATA response primitive, then the LLC shall issue it to the formatter with an acknowledgement number  $N(R) = V(R)$ ;
    - if there is a waiting acknowledgement and a TL-DATA request primitive available, then the LLC shall:
      - i) set  $N(S) = V(S)$  for the TL-SDU to be sent;
      - ii) set  $N(R) = V(R)$  for the waiting acknowledgement;
      - iii) form the corresponding BL-ADATA PDU and issue it to the formatter;
    - if the size of the TL-DATA plus the size of the BL-ADATA LLC header exceeds the size of the TM-SDU in this MAC block, then the LLC shall issue a BL-ACK PDU with an acknowledgement number  $N(R) = V(R)$  to the formatter without any service user data and send the TL-SDU using BL-DATA PDU;
    - if there is a waiting acknowledgement and neither a TL-DATA response nor a TL-DATA request primitive available, then the LLC shall issue a BL-ACK PDU with an acknowledgement number  $N(R) = V(R)$  to the formatter without any service user data;
    - if there is no waiting acknowledgement but a TL-SDU is available, then the LLC shall set  $N(S) = V(S)$  for the TL-SDU to be sent, form the corresponding BL-DATA PDU and issue it to the formatter.
  - e) a TMA-REPORT indication primitive confirming the handle to the request parameter;
  - f) a TMA-REPORT indication primitive (one of the complete TM-SDU transmission indications) and if it is due to a PDU which contained service user data in either a BL-DATA or BL-ADATA PDU and the PDU transmission was successful and complete transmission by random access or complete transmission by reserved access or stealing, then the LLC shall start the re-try timer T.251; and in any case, if this is the first transmission of the TL-SDU, then the LLC shall issue a TL-REPORT indication primitive (first complete transmission) to the service user;
  - g) a TMA-REPORT indication primitive (random access failure) and if it is due to a PDU which contained service user data, then the LLC shall inform the service user of unsuccessful transmission by TL-REPORT primitive (failed transfer), and delete the corresponding TL-SDU from the sending buffer. If the report was due to a BL-DATA or BL-ADATA PDU, the LLC shall increment  $V(S)$ ;

- h) a TMA-REPORT indication primitive (fragmentation failure) and:
  - if it is due to a BL-ACK PDU, then the LLC shall discard the optional TL-SDU;
  - if the report is due to a BL-DATA or BL-ADATA PDU and the number of allowed retransmissions N.252 of the corresponding TL-SDU is not exceeded, then the LLC shall keep the TL-SDU for re-transmission and inform the formatter by a DATA\_IN\_BUFFER signal; or
  - otherwise the LLC shall inform the service user of unsuccessful transmission by TL-REPORT primitive (failed transfer), increment V(S) and delete TL-SDU from the sending buffer.
- i) re-try timer T.251 expires and
  - if the number of allowed retransmissions N.252 is not exceeded, then the LLC shall keep the TL-SDU in the sending buffer for re-transmission and inform the formatter by a DATA\_IN\_BUFFER signal; or
  - otherwise the LLC shall inform the service user of unsuccessful transmission by TL-REPORT primitive (failed transfer), increment V(S) and delete TL-SDU from the sending buffer;
- PDU from the peer entity:
  - j) a BL-ACK and then:
    - if there is a TL-SDU waiting for a re-transmission in the sending buffer, then:
      - if the TL-SDU number (in the BL-ACK PDU)  $N(R) = V(S)$ , then the LLC shall confirm the success of the transmission to the service user by a TL-DATA confirm (successful transfer) primitive and deliver the contained TL-SDU, if any upon condition that the FCS calculation is successful in case the optional FCS is used, increment V(S), delete the TL-SDU waiting for a re-sending from the sending buffer and stop the re-try timer T.251; or
      - if the TL-SDU number (in the BL-ACK PDU)  $N(R)$  is not equal to V(S), then the LLC shall deliver contained TL-SDU, if any upon condition that the FCS calculation is successful in case the optional FCS is used, using TL-DATA indication primitive; and
      - if the number of allowed retransmissions N.252 of the TL-SDU is not exceeded, then the LLC shall keep the corresponding TL-SDU in the sending buffer for re-transmission and inform the formatter by the DATA\_IN\_BUFFER signal; or
      - if the number of allowed retransmissions N.252 of the TL-SDU is exceeded, then the LLC shall inform the service user of unsuccessful transmission by a TL-REPORT indication primitive (failed transfer), increment V(S), stop re-try timer T.251 and discard the corresponding TL-SDU from the sending buffer;
      - if there is no TL-SDU waiting for a re-transmission in the sending buffer, then the LLC shall deliver contained TL-SDU, if any upon condition that the FCS calculation is successful in case the optional FCS is used, using TL-DATA indication primitive;
  - k) a BL-DATA PDU and then:
    - i) the LLC shall delete the possible BL-ACK PDU from the sending buffer;
    - ii) the LLC shall:
      - if the FCS is used and it is correct or FCS is not used, then the LLC shall select a new handle to the request parameter value and deliver TL-SDU to the service user in a TL-DATA indication service primitive (handle to the request), memorize a waiting acknowledgement with number  $V(R) = N(S)$ , start to wait for TL-DATA response primitive and inform the formatter by the DATA\_IN\_BUFFER signal;

NOTE 1: As both MLE and LLC select handle to the request parameter values and both could select the same value a mechanism should be implemented to prevent it such as a sub-division of the value space.

- if the FCS is used and it is not correct and no other not yet acknowledged data received before the PDU with incorrect FCS was received, then no acknowledgement is sent, i.e. LLC action against the received BL-DATA with incorrect FCS is as that PDU was not received.
- l) a BL-ADATA PDU and then the LLC shall separate the acknowledgement N(R) and incoming TL-SDU including N(S) and shall continue as if LLC had received a BL-ACK PDU (without service user data) first (case j) and then a BL-DATA PDU (case k).

The LLC shall set the stealing permission parameter to "steal within time T.214" for the BL-ACK PDU in the basic link protocol in case the MAC currently has traffic transmit permission. The LLC should also set PDU priority level = 5 (though this parameter will not normally be used by the MAC).

NOTE 2: At the reception of a new BL-DATA PDU before acknowledging the previous received BL-DATA PDU the LLC stops all acknowledgement actions of the previous TL-SDU independently of the TL-SDU number N(S).

NOTE 3: The defined protocol and PDU numbering supports the receiving peer entity to request a TL-SDU re-sending, but it does not guarantee alone a safe mechanism for suppression of duplicate TL-SDUs.

NOTE 4: The transmission of a TL-SDU from a TL-DATA request primitive is totally independent of any data transmission in the other direction. On the other hand a TL-SDU from a TL-DATA response primitive is normally transferred in the corresponding acknowledgement of the TL-DATA indication primitive. If the TL-DATA response primitive is delayed too much, then the TL-SDU will be sent in a BL-DATA PDU and it will be acknowledged by a TL-DATA confirm primitive.

NOTE 5: The random access failure prevents further TL-SDU sending re-tries and, to increase the probability to get an emergency message through, the MAC will use more random access re-tries for higher priority TL-SDUs.

NOTE 6: The information "First complete transmission" by random access may be used in cancellation process in addition or in place of a request to the MAC.

## 22.3.2.4 Unacknowledged data transfer in the basic link

### 22.3.2.4.0 General

The procedures in an MS for unacknowledged data transfer in the basic link are described in the following clauses.

#### 22.3.2.4.1 Actions on TL-UNITDATA request primitive (sending entity)

During sending of unacknowledged service user data the LLC may receive:

- a) a TL-UNITDATA request primitive (handle to the request) from the service user and then:
  - the LLC may issue an immediate TL-REPORT indication primitive containing the handle to the request parameter to the TL-UNITDATA request primitive;
  - if requested by the service user, then the LLC shall calculate and append a FCS to the SDU;
  - the LLC shall store TL-SDU in priority order into the sending buffer for sending N.253 + 1 times, and inform formatter with the DATA\_IN\_BUFFER signal;
- b) a MAC-READY from the formatter and then the LLC shall deliver the highest priority (unacknowledged service) TL-SDU as a BL-UDATA PDU to the formatter;
- c) a TMA-REPORT indication primitive confirming the handle to the request parameter;
- d) a TMA-REPORT indication primitive (successful complete transmission by random access), and then the LLC shall remove the TL-SDU from the transmitting buffer and deliver a TL-REPORT indication primitive (transfer completed) to the service user;

- e) a TMA-REPORT indication primitive (complete transmission by stealing or by reserved access), and if that TL-SDU has now been completely transmitted  $N.253 + 1$  times, then the LLC shall remove the TL-SDU from the transmitting buffer and deliver a TL-REPORT indication primitive (transfer completed) to the service user;
- f) a TMA-REPORT indication primitive (failure of fragmentation process) and then:
  - if  $N.253 > 0$ , the LLC shall try to re-send the TL-SDU so that there shall be at maximum  $N.253 + 1$  failed transmissions (in addition to the  $N.253 + 1$  complete transmissions); if there have not been  $N.253 + 1$  complete transmissions when the maximum number of failed transmissions  $N.253 + 1$  has been reached, then the LLC shall remove the TL-SDU from the sending buffer and issue a TL-REPORT indication primitive (failed transfer) to the service user;
  - if  $N.253 = 0$ , the LLC shall try to re-send the TL-SDU so that there shall be at maximum two failed transmissions (or the TL-SDU has been completely transmitted); if there has not been one complete transmission when the maximum of two failed transmissions has been reached, then the LLC shall remove the TL-SDU from the sending buffer and issue a TL-REPORT indication primitive (failed transfer) to the service user;
- g) a TMA-REPORT indication primitive (random access failure) and then the LLC shall remove TL-SDU from the sending buffer and issue a TL-REPORT indication primitive (failed transfer) to the service user.

NOTE 1: The service user may indicate the required number of repetitions (i.e.  $N.253$ ) in the TL-UNITDATA request primitive, in which case that value is applied for transmission of the TL-SDU. If the service user does not indicate the required number of repetitions, the value of  $N.253$  chosen by the MS designer is used (see annex A).

NOTE 2: The MS may send more than one BL-UDATA PDU in one MAC block (using MAC PDU association).

NOTE 3: For  $N.253 > 0$ , the MS should not send the same BL-UDATA PDU more than once in one MAC block. The unacknowledged basic link service does not guarantee in-order delivery at the receiving entity. Therefore, in order to use the capacity of MAC blocks by PDU association, the MS may interleave retransmissions of multiple BL-UDATA PDUs.

NOTE 4: In the DATA\_IN\_BUFFER signal, the LLC may include all outstanding unacknowledged basic link data as outstanding data ready to be sent, so that the MAC can indicate a reservation requirement for that data.

#### 22.3.2.4.2 Actions on BL-UDATA PDU (receiving entity)

Upon reception of a BL-UDATA PDU from the formatter:

- i) if indicated by the received PDU, LLC shall calculate FCS and:
  - if the FCS is correct, the LLC shall inform the service user of a reception of a TL-SDU using a TL-UNITDATA indication primitive;
  - if the FCS is not correct, the LLC shall discard the SDU.
- ii) if the received PDU does not contain FCS, then the LLC shall issue the TL-SDU to the service user using a TL-UNITDATA indication primitive.

NOTE: The basic link protocol does not suppress received duplicates.

## 22.3.3 Advanced link procedures for the acknowledged service

### 22.3.3.0 General

The LLC advanced link protocol of the MS is modelled by processes: AL\_MAIN, AL\_TX, AL\_RX and Formatter, the latter being common also with the basic link and unacknowledged advanced link services and layer 2 signalling, refer to figure 22.2. Refer to clause 22.3.1.7 for formatter processes.

The present document models the numbering of TL-SDUs and acknowledgements and local function indicators by local variables. Each advanced link shall employ separate sets of variables, parameters and timers.

At the data sending entity:

- N(S) TL-SDU number in the sent data PDUs;
- N(R) TL-SDU number in the received acknowledgement PDUs;
- S(S) Segment number in the sent data PDU;
- S(R) Segment number in the received acknowledgement PDU.

At the data receiving entity:

- N(S) TL-SDU number in the received data messages;
- N(R) TL-SDU number in the sent acknowledgement messages;
- S(S) Segment number in the received data PDU;
- S(R) Segment number in the sent acknowledgement PDU.

Timers and constants are defined in annex A.

In figure 22.2 the AL-MAIN controls independently the state of each advanced link.

Each advanced link set-up, data transfer, LLC reconnection and disconnection phase is modelled by states:

- IDLE link is not ready for data transfer;
- WAIT\_IN\_CONNECT link is in the incoming set-up phase;
- WAIT\_OUT\_CONNECT link is in the outgoing set-up phase;
- WAIT\_DISCONNECT link is waiting for outgoing disconnection;
- WAIT\_RECONNECT link is waiting for LLC reconnection;
- CONNECTED link is ready for data transfer.

The acknowledged information transfer in the CONNECTED state of each advanced link (N.261) is modelled by a single state in the data sending process:

- AL\_TX\_READY transmitter is ready to send the next TL-SDU;

and respectively by a single state in the data receiving process:

- AL\_RX\_READY receiver is ready to receive data from the MAC.

NOTE 1: It is recommended that an MS which only supports  $\pi/4$ -DQPSK operation does not use fragmentation for sending advanced link PDUs.

NOTE 2: If the MS supports D8PSK operation, fragmentation is needed when a segment cut for transmission using  $\pi/8$ -D8PSK modulation is re-transmitted using  $\pi/4$ -DQPSK modulation.

NOTE 3: It is recommended that an MS does not normally use fragmentation for sending advanced link data PDUs on a QAM channel. However, fragmentation may be needed in some cases. For example, after a reduction of bandwidth (for example, if the bandwidth changes from 50 kHz to 25 kHz), fragmentation may be needed for re-transmissions of segments cut for transmission on the old channel. Alternatively, the advanced link may be reset after a reduction of bandwidth.

### 22.3.3.1 Advanced link establishment for the acknowledged service

#### 22.3.3.1.0 General

The service user shall set up the advanced link before any data transmission may occur. The advanced link is available for data transfer until the service user or the LLC entity disconnects it. The advanced link number may be used locally as a part of the link identifier related to an advanced link. The established advanced link can be used for two-way information transfer.

There can be only one connection set-up in progress at the same time. If there are colliding set-ups from both peer entities, then those will be merged into a single set-up process.

The service user shall define the quality of service by setting up an advanced link and later by selecting that advanced link for the data transmission. The quality of service parameters applicable to the LLC layer are defined in clause 20. The set-up report parameter shall be used to indicate the progress of the connection establishment.

The procedures for sending and reception of the AL-SETUP PDU are defined in clauses 22.3.3.1.1, 22.3.3.1.2, 22.3.3.1.3 and 22.3.3.1.4. The following rules also apply:

- a) The LLC should not send an AL-SETUP PDU for an extended acknowledged advanced link to an LLC that does not support extended advanced link(s).

NOTE 1: MS support of extended advanced link(s) is indicated in the "class of MS" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

For CA, BS support of extended advanced links is indicated in the "extended services broadcast" element in the SYSINFO and SYSINFO-Q PDUs; see clause 21.

For DA, the BS always supports advanced links (both extended and original) when the "system wide services" element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "normal mode"; see clause 18. When the "system wide services" element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDU indicates "system wide services temporarily not supported", the MS LLC may send an AL-SETUP PDU to the BS for an extended (or original) acknowledged advanced link; however the BS in this mode may temporarily not support advanced links, in which case the BS may send the AL-DISC PDU with a report "service temporarily unavailable"; if the MS receives an AL-DISC PDU with report "service temporarily unavailable", the MS should not continue to attempt to establish advanced links while the "system wide services" element indicates "system wide services temporarily not supported" (though the MS is not precluded from occasionally attempting to establish advanced links).

NOTE 2: The BS may send the AL-DISC PDU with a report "close" if it receives AL-DATA(-AR), AL-FINAL(-AR), AL-X-DATA(-AR) or AL-X-FINAL(-AR) PDUs when it temporarily does not support advanced links; see clause 22.3.3.3.2.

- b) When the LLC sends an AL-SETUP PDU for the original acknowledged advanced link, it shall use the lowest free (i.e. unused) advanced link number for that address.

NOTE 3: Therefore, if no extended acknowledged advanced links exist for that address, advanced link number 1 is used for the original acknowledged advanced link; in particular, if either LLC does not support extended advanced link(s) then advanced link number 1 is always used for the original acknowledged advanced link. If both LLCs support extended advanced link(s) and advanced link number 1 is in use for an extended acknowledged advanced link then the next free advanced link number is used.

If an extended acknowledged advanced link is proposed and the peer entity offers an original acknowledged advanced link, the advanced link number is unchanged in the response AL-SETUP PDU. Therefore, in this case, the advanced link number in the AL-SETUP PDU for the original acknowledged advanced link is not necessarily the lowest free advanced link number for that address.

### 22.3.3.1.1 Actions on TL-CONNECT request primitive (set-up phase sending entity)

Upon reception of a TL-CONNECT request primitive (handle to the request) in any state, the LLC shall:

- i) if the corresponding advanced link is already set up, then the LLC shall cease both sending and reception actions, if needed cancel the relevant MAC layer SDU by a TMA-CANCEL request primitive, empty relevant data buffers and prepare an AL-SETUP PDU with a report "reset"; or  
if the corresponding advanced link is not already set up, then the LLC shall prepare an AL-SETUP PDU with a report "service definition";
- ii) set the re-try counter to allow the maximum number of connection set-up retries N.262;
- iii) inform the formatter using the DATA\_IN\_BUFFER signal and enter "WAIT\_OUT\_CONNECT" state.

NOTE: The LLC selects parameters for an AL-SETUP PDU according to the TL-CONNECT request primitive parameters and current LLC capabilities e.g. available buffer sizes; see clause 20 for parameter definitions and clause 21 for PDU definitions. Suitable parameters for a AL-SETUP PDU depend on the quality negotiation between the service user and the DLL. The negotiation method is implementation dependent.

In the "WAIT\_OUT\_CONNECT" state the LLC may receive:

Local indication:

- a) a MAC-READY signal and then the LLC shall deliver the waiting AL-SETUP PDU, if any, to the formatter;
- b) a TMA-REPORT indication primitive confirming the handle to the request;
- c) a TMA-REPORT indication primitive (complete transmission) and if reason is "successful complete transmission by random access" or "complete transmission by reserved access or stealing", then the LLC shall start set-up waiting timer T.261;
- d) a TMA-REPORT indication primitive (random access failure) and then the LLC shall inform a set-up failure to the service user by TL-REPORT indication primitive (set-up failure) and return into the "IDLE" state for this advanced link;
- e) set-up waiting time-out T.261 indication and:
  - if more retries (N.262) are available, then the LLC shall issue the previous AL-SETUP PDU into the transmission buffer and inform formatter by the DATA\_IN\_BUFFER signal;
  - if all retries (N.262) are used, then the LLC shall inform a set-up failure to the service user by TL-REPORT indication primitive (set-up failure) and return into the "IDLE" state for this advanced link;

PDU from peer entity:

- f) an AL-SETUP PDU with the report "success" and then the LLC shall issue a TL-CONNECT confirm primitive to the service user, stop set-up waiting timer T.261, and prepare the advanced link for data transfer in state "CONNECTED";
- g) an AL-SETUP PDU with report "service change" and then the LLC shall inform the service user by a TL-CONNECT indication primitive. The service user shall respond with a TL-CONNECT response primitive and the LLC shall act accordingly depending on the value of "Set-up report" parameter (see clause 20.2.4.63) contained in the TL-CONNECT response primitive:
  - if the set-up report indicates that the parameters are acceptable, then the LLC shall prepare an AL-SETUP PDU with report "success" and inform formatter using DATA\_IN\_BUFFER signal. The LLC shall continue in the "WAIT\_IN\_CONNECT" state as defined in clause 22.3.3.1.2 e) to h);
  - if the set-up report indicates that the parameters are not acceptable, but there is a possibly suitable parameter set available, then the LLC shall prepare an AL-SETUP PDU with report "service change" and inform formatter using DATA\_IN\_BUFFER signal;

- if the parameters are not acceptable and there is no suitable parameter set available, the connection establishment is rejected and then the LLC shall prepare an AL-DISC PDU with report "service not supported" and inform formatter using DATA\_IN\_BUFFER signal and deliver the AL-DISC PDU to the formatter as the response to the MAC-READY signal and then inform the service user by a TL-DISCONNECT indication primitive "set-up failure" and return to the "IDLE" state for this advanced link.
- h) an AL-SETUP PDU with report "service definition" and then the LLC shall continue as described in clause 22.3.3.1.2 for the "IDLE" state;
- i) an AL-DISC PDU with report "service not supported", "service temporarily unavailable" or "reject" and then the LLC shall inform the service user by the corresponding TL-DISCONNECT indication primitive and return to the "IDLE" state for this advanced link.

The MS may receive in the TMA-UNITDATA indication primitive carrying an AL-SETUP PDU the "Channel change response required" parameter set to "true"; then the MS shall pass it in the corresponding TL-CONNECT primitive with the "Channel change handle" parameter to MLE.

### 22.3.3.1.2 Actions on AL-SETUP PDU reception (set-up phase receiving entity)

If the LLC is capable of supporting advanced link, then upon reception of an AL-SETUP PDU for an acknowledged advanced link with one of the reports "service definition", "service change" or "reset" when in the "IDLE" state for that advanced link number (and address), the LLC shall inform the service user by a TL-CONNECT indication primitive with corresponding report and start to wait in state "WAIT\_IN\_CONNECT".

If the LLC does not for the moment support advanced link, then upon reception of an AL-SETUP PDU the LLC shall prepare an AL-DISC PDU with a report "service temporarily unavailable", inform formatter by DATA\_IN\_BUFFER signal and issue the AL-DISC PDU as a response to the next MAC-READY signal.

If the LLC does not at all support advanced link, then upon reception of an AL-SETUP PDU the LLC may prepare an AL-DISC PDU with a report "service not supported", inform formatter by DATA\_IN\_BUFFER signal and issue the AL-DISC PDU as a response to the next MAC-READY signal.

While waiting in state "WAIT\_IN\_CONNECT" the LLC may receive:

Service user initiated service primitives:

- a) a TL-CONNECT response primitive with the same parameters as in the TL-CONNECT indication primitive and then the LLC shall prepare an AL-SETUP PDU with same parameters as in the received AL-SETUP PDU with a report "success" and inform the formatter by a DATA\_IN\_BUFFER signal;
- b) a TL-CONNECT response primitive with different parameters (less QoS) as in the TL-CONNECT indication primitive and then the LLC shall prepare an AL-SETUP PDU with suitable parameters (QoS) and with a report "service change", inform the formatter by DATA\_IN\_BUFFER signal and continue in the "WAIT\_OUT\_CONNECT" state as defined in clause 22.3.3.1.1;
- c) a TL-CONNECT request primitive and then the LLC shall continue as if it had received that primitive from the service user as a set-up phase sending entity, see clause 22.3.3.1.1;
- d) a TL-DISCONNECT request primitive and then the LLC shall prepare an AL-DISC PDU with a report "reject", inform formatter by DATA\_IN\_BUFFER signal and issue the AL-DISC PDU to the formatter as a response to the next MAC-READY signal and then return to the "IDLE" state for this advanced link.

Local indications due to the AL-SETUP PDU with the report "success" sending:

- e) a MAC-READY signal and then the LLC shall deliver the waiting AL-SETUP PDU to the formatter;
- f) a TMA-REPORT indication primitive confirming the handle to the request;
- g) a TMA-REPORT indication primitive (successful complete transmission by random access or complete transmission by reserved access or stealing) and then the LLC shall prepare the advanced link for data transfer in state "CONNECTED";
- h) a TMA-REPORT indication primitive (random access failure) and then the LLC may inform the service user by a TL-DISCONNECT indication primitive (set-up failure) and the LLC shall return into the "IDLE" state for this advanced link.

NOTE 1: The LLC entity should not normally receive an AL-SETUP PDU with a report "service change" or "reset" when in the "IDLE" state for that advanced link, but if this happens, then the LLC should start normal connection establishment as if the received report were "service definition".

NOTE 2: The LLC entity should not normally receive an AL-SETUP PDU with a report "success" in state "IDLE" for that advanced link or in state "WAIT\_IN\_CONNECT" but, if this happens, then:

- if in state WAIT-IN-CONNECT, the LLC should cancel any AL-SETUP PDU with the report "success" sending; and
- in either case, the LLC should start normal connection establishment sending an AL-SETUP PDU with a report "service definition" as defined in clause 22.3.3.1.1.

NOTE 3: A TL-CONNECT response primitive from the service user with a different set of parameters than in the corresponding TL-CONNECT indication primitive is taken as a new connect request and the LLC will respond to it with a TL-CONNECT confirm primitive before the data transfer may start.

The MS may receive in the TMA-UNITDATA indication primitive carrying an AL-SETUP PDU the "Channel change response required" parameter set to "true"; then the LLC shall pass it in the corresponding TL-CONNECT primitive with the "Channel change handle" parameter to MLE.

#### 22.3.3.1.3 Actions on AL-SETUP PDU reception (data transfer state)

Upon reception of an AL-SETUP PDU for an acknowledged advanced link with a report "reset", "service definition" or "service change" when in the "CONNECTED" state for that advanced link number (and address) then:

- i) the LLC shall cease both sending and reception actions for that advanced link, empty relevant data buffers and, if needed, cancel any MAC layer sending by TMA-CANCEL request primitive; and
- ii) the LLC shall inform the service user of the reset by a TL-CONNECT indication primitive with the report "reset" and start to wait connection set-up progress in state "WAIT\_IN\_CONNECT" as defined in clause 22.3.3.1.2.

#### 22.3.3.1.4 Actions on original AL-SETUP PDU reception on different link number (data transfer state)

Upon reception of an AL-SETUP PDU for an original acknowledged advanced link with a report "service definition", "service change" or "reset" when in the "CONNECTED" state for an original acknowledged advanced link for that address but with a different advanced link number then:

- i) the LLC shall cease both sending and reception actions for the existing original advanced link, empty relevant data buffers and, if needed, cancel any MAC layer sending by TMA-CANCEL request primitive; and
- ii) the LLC shall inform the service user of the implicit disconnection of the existing original advanced link and go into the "IDLE" state for that advanced link; and
- iii) the LLC shall inform the service user of the incoming set-up by a TL-CONNECT indication primitive and start to wait connection set-up progress in state "WAIT\_IN\_CONNECT" as defined in clause 22.3.3.1.2.

NOTE: This is an exceptional case which may occur occasionally for an LLC that supports extended advanced link(s). It should not occur for an LLC that does not support extended advanced link(s).

### 22.3.3.2 Acknowledged data transfer on the original advanced link

#### 22.3.3.2.0 General

In the advanced link, each data PDU in the acknowledged information transfer is identified by two numbers: a TL-SDU sequence number  $N(S)$  and a segment sequence number  $S(S)$ . For the original advanced link, the TL-SDU sequence number is a three-bit number incremented in a modulo manner with each transmitted TL-SDU. After the connection set-up or after a reset, the data sending LLC entity shall start the TL-SDU numbering from "0". The segment sequence number is an absolute eight-bit number indicating segments inside a TL-SDU. Those numbers are used in the segmentation and re-assembly processes and in the selective re-transmission process. The acknowledgement contains the corresponding TL-SDU sequence number  $N(R)$  and, in the selective acknowledgement PDU, a segment sequence number  $S(R)$ . The acknowledgement cannot carry any layer 3 information.

For the original advanced link, the advanced link number is not included in the data transfer and acknowledgement PDUs. The advanced link number in the data transfer and acknowledgement PDUs shall be implicitly assumed to be as indicated in the AL-SETUP PDU for the original acknowledged advanced link.

The advanced link can be used for two-way information transfer.

**NOTE:** If the BS establishes or accepts an advanced link for the acknowledged service to carry TL-SDUs with a maximum length of 4 096 octets then, in the case of a 25 kHz QAM channel, the BS needs to assign an event label for that MS address for use on that channel; see clause 23.4.1.2.3.1. This is needed in order to enable absolute segment numbering with the eight-bit segment sequence number.

#### 22.3.3.2.1 Segmentation and sequencing

The data sending advanced link LLC entity shall segment a TL-SDU, if the size of it exceeds:

- when on a  $\pi/4$ -DQPSK or D8PSK channel: the available MAC SDU size; or
- when on a 25 kHz or 50 kHz QAM channel: the available MAC SDU size in a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth; or
- when on a 100 kHz or 150 kHz QAM channel: the available MAC SDU size in half of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth.

The MAC sub-layer indicates the next available segment size in the MAC-READY signal and the LLC should use the whole available size with possible exception of the last segment.

Segments shall be sent in sequence. In order to allow a re-assembly in the selective re-transmission, the segments are numbered using a  $S(S)$  starting from "0" for each TL-SDU. The segment numbering is absolute, therefore a TL-SDU shall not comprise more than 256 segments.

The re-transmission of a segment shall not change the size of that segment, refer to clause 22.3.3.2.3.

For the original advanced link, the LLC shall use either AL-DATA or AL-DATA-AR PDU for a segment sending if the segment is not the last segment of a TL-SDU, and the LLC shall use either AL-FINAL or AL-FINAL-AR PDU if the segment is the last segment of a TL-SDU. The LLC shall use either AL-FINAL or AL-DATA PDUs if no acknowledgement is needed at this moment from the peer entity, and either AL-FINAL-AR or AL-DATA-AR PDU if acknowledgement is needed at this moment from the peer entity, refer to clause 22.3.3.2.3.

**NOTE:** The TL-SDU, as used in this definition, contains the FCS.

#### 22.3.3.2.2 Re-assembly

Re-assembly is an operation opposite to segmentation. The data receiving LLC entity shall re-assemble the TL-SDU from the received segments. The acknowledged advanced link protocol shall deliver received TL-SDUs to the service user in the TL-SDU sequence number order.

At the reception of the first received segment (or every received segment) of a new SDU, the BS LLC entity sends a TL-RECEIVE indication primitive to the service user indicating that data input is in progress.

### 22.3.3.2.3 Acknowledgement and segment re-transmission mechanisms

In this LLC protocol the data sending entity is responsible for requesting acknowledgements from the data receiving entity. The data sending LLC may request an acknowledgement from the peer LLC and potentially cease data transmission by using either the AL-DATA-AR or AL-FINAL-AR PDU. The data sending LLC shall request an acknowledgement at latest, when it cannot continue sending due to the closing of TL-SDU window. The data sending LLC should request an acknowledgement each time there is no more data for sending or there will be a pause in sending for other reasons. When on a  $\pi/4$ -DQPSK channel, the data sending LLC should generally minimize acknowledgement requests in good propagation situations. When on a D8PSK or QAM channel, the choice of when the data sending LLC requests acknowledgements may be affected by the link adaptation algorithm used by the transmitting MS or BS.

In addition to the requested acknowledgements the data receiver may choose to send acknowledgements at any time for its own purposes e.g. to clean up receiving buffers. When on a D8PSK or QAM channel, the choice of when the data receiver sends acknowledgements may be affected by link adaptation aspects.

The data receiving entity acknowledges both whole TL-SDUs and selectively segments of TL-SDUs by either AL-ACK or AL-RNR PDUs depending on the flow control needs, refer to clause 22.3.3.2.5. The data sending entity shall re-transmit the segments marked as bad in the last received AL-ACK or AL-RNR PDU. The re-transmission of segments shall start from the oldest segment in the oldest TL-SDU and continue until all segments for which a re-transmission is requested are transmitted. If the data sending entity receives an acknowledgement for the whole TL-SDU, it informs the service user of the correct transfer of the layer 3 data by issuing a TL-DATA confirm primitive. A segment shall keep its original sent segment number S(S), which indicates its absolute position inside the corresponding TL-SDU. The same sent TL-SDU number N(S) shall be used until all its segments have been successfully transmitted and the whole TL-SDU has been acknowledged (see clause 22.3.3.2.6) or TL-SDU transmission is failed or the advanced link is disconnected.

Upon reception of the acknowledgement request indicated by the AL-DATA-AR or AL-FINAL-AR PDU, the data receiver entity shall send either the AL-ACK or the AL-RNR PDU, refer to clause 22.3.3.2.5 for flow control, with one or more acknowledgement blocks:

- i) the N(R) element shall indicate which TL-SDU is acknowledged;
- ii) if the acknowledgement is for a whole TL-SDU, then the LLC shall set the acknowledgement length element to:
  - value 000000<sub>2</sub> if the data receiver accepts the TL-SDU;
  - value 111111<sub>2</sub> if the data receiver requests a re-sending of the TL-SDU; and
  - there shall be no other elements in that acknowledgement block;
- iii) if the data receiver selectively acknowledges segments of the TL-SDU then:
  - the acknowledgement length element shall indicate the number of acknowledged segments; and
  - the S(R) element shall indicate the absolute position of the oldest not yet received segment in the TL-SDU; and
  - the bit map shall indicate the status of each segment starting from the next segment after the S(R) and moving forwards one segment at a time, up to the limit imposed by the last correctly received segment or by the available room in the AL-ACK or AL-RNR PDU; the status of the segment (STATUS) shall be set to "1" if it is correctly received and to "0" if it is not correctly received.

The data receiving entity shall note the TL-SDU number in the AL-DATA-AR or AL-FINAL-AR. The data receiving entity shall include an acknowledgement block for any older TL-SDUs that are not yet completely received or that have not yet been acknowledged as completely received, if permitted by the available room in the AL-ACK or AL-RNR PDU. The data receiving entity should also include an acknowledgement block for the TL-SDU corresponding to the AL-DATA-AR or AL-FINAL-AR. If an acknowledgement block for the TL-SDU corresponding to the AL-DATA-AR or AL-FINAL-AR is included, the data receiving entity may include an acknowledgement block for newer TL-SDUs. If the acknowledgement blocks do not fit within one MAC block, then the data receiving entity may send multiple AL-ACK (or AL-RNR) PDUs.

NOTE 1: If the data receiving entity wishes to send more than one acknowledgement block which refers to the same TL-SDU, those acknowledgement blocks should be included within the same AL-ACK (or AL-RNR) PDU, using fragmentation if necessary; the data receiving entity is not permitted to divide acknowledgement blocks which refer to the same TL-SDU between multiple AL-ACK (or AL-RNR) PDUs.

If the data sending entity does not receive an acknowledgement message either AL-ACK or AL-RNR PDU within acknowledgement waiting time T.252, then:

- if the SDU window size for TL-SDU N.272 is fully used, then the data sending LLC shall repeat its acknowledgement request as above by using an AL-DATA-AR or AL-FINAL-AR PDU, as appropriate, for an already transmitted segment; or
- if the SDU window size for TL-SDU N.272 is not fully used but there is currently no more data to send, then the data sending LLC should repeat its acknowledgement request as above by using an AL-DATA-AR or AL-FINAL-AR PDU, as appropriate, for an already transmitted segment; or
- if the SDU window size for TL-SDU N.272 is not fully used, and there is more data to send, then the data sending LLC may continue its transmission by using AL-DATA(-AR) or AL-FINAL(-AR) PDU as appropriate.

NOTE 2: The data sending entity may continue data transmission within the TL-SDU window independently of the acknowledgement waiting timer.

#### 22.3.3.2.4 TL-SDU re-transmission

In the case that all the segments of a TL-SDU have been received, but the FCS verification has failed, the whole TL-SDU shall be re-transmitted if within the allowed number of TL-SDU retransmissions N.273. The data receiver shall indicate the FCS failure by setting value 11111<sub>2</sub> to the acknowledgement length information element in the AL-ACK or AL-RNR PDU. On the data transmitter side, this TL-SDU shall be re-transmitted using the same TL-SDU discriminator and starting transmission from the first segment.

Refer to clause 22.3.3.2.6 for reasons of the data sending entity to re-transmit a TL-SDU.

If the maximum number of TL-SDU re-transmissions N.273 is exceeded, the data sending LLC shall abandon the transmission of that TL-SDU and report an error to the service user using a TL-REPORT indication primitive "failed transfer". The service user should stop using the advanced link and either reset or disconnect it, refer to clauses 22.3.3.1.1 and 22.3.3.3 for protocol actions.

#### 22.3.3.2.5 Flow control

During the transmission in an advanced link, the data receiving entity has the possibility to interrupt the data transmitting entity from sending new TL-SDUs. The data receiving entity shall use as acknowledgements either an AL-ACK or an AL-RNR PDU, if the data receiver may continue to receive more data or is not capable of receiving more data respectively. The AL-RNR PDU shall also acknowledge already received PDUs and/or segments of PDUs.

When an AL-ACK or AL-RNR PDU is sent over the air interface, it shall reflect the actual situation at the data receiver at the transmission time of this acknowledgement.

Upon reception of an AL-RNR PDU the data transmitting entity shall wait until either the peer entity sends an AL-ACK PDU or the receiver not ready validity timer for the data sending entity T.271 expires (or until the link is disconnected or reset). The data sender should continue sending of those TL-SDUs, which are partially acknowledged in the AL-RNR PDU or previously. The data receiving entity may need to send more than one AL-RNR PDU when there are more segments or PDUs waiting for positive or negative acknowledgement than fit into one AL-RNR PDU.

If the receiver not ready validity timer for the data sending entity T.271 expires, the data sending entity shall try to start the sending of the TL-SDUs from the first unacknowledged PDU if there is still room in the TL-SDU sending window N.272, or from the last segment of the last already acknowledged TL-SDU, if there is no room in the TL-SDU window. If the data receiving LLC cannot accept the new TL-SDU, it shall acknowledge the last already received and acknowledged TL-SDU by an AL-RNR PDU.

The data receiving entity starts the receiver not ready validity timer T.272 when it sends an AL-RNR PDU over the air interface. If T.272 expires and the data receiving entity is still incapable of receiving data, it may restart T.272 and send another AL-RNR PDU. T.272 is reset when the data receiving entity sends an AL-ACK PDU over the air interface which indicates that the data receiver is again capable of receiving data.

#### 22.3.3.2.6 Actions on TL-DATA request primitive (data sending entity)

During acknowledged data transfer the LLC data sending entity may receive (in state "AL\_TX\_READY") from the service user:

- a) a TL-DATA request primitive (handle to the request) and then:
  - i) the data sending LLC may issue a TL-REPORT indication primitive confirming the handle to the request parameter;
  - ii) the LLC shall calculate the FCS and append it to the TL-SDU;
  - iii) the LLC shall save the TL-SDU with the FCS into sending buffer and inform the MAC layer how much data is available for sending by the DATA\_IN\_BUFFER signal, see clause 22.3.1.7.2;

Local indications:

- b) MAC-READY signal and then:
  - if there are no segments pending for re-transmission, the LLC shall format a new segment of the TL-SDU in the sending buffer as defined in clause 22.3.3.2.1 and issue it to the formatter and set the corresponding segment re-transmission counter;
  - if there is at least one segment pending for re-transmission and the maximum number of segment retransmissions N.274 of that segment is not exceeded, then the LLC shall select the oldest segment, for which there is a re-transmission request pending and issue the PDU to the formatter;
  - if there is at least one segment pending for re-transmission and the maximum number of the segment retransmissions N.274 of that segment is exceeded but the maximum number of TL-SDU retransmissions N.273 is not exceeded, then the LLC shall start re-sending of the complete TL-SDU (using the original segmentation) and issue it to the formatter;
  - if there is at least one segment pending for re-transmission and both the maximum number of segment retransmissions N.274 of that segment and the maximum number of TL-SDU retransmissions N.273 are exceeded, then the LLC shall inform the service user about TL-SDU transmission failure by a TL-REPORT indication primitive (failed transfer);
- c) an indication, that the acknowledgement waiting timer T.252 has expired, refer to acknowledgement mechanisms in clause 22.3.3.2.3 for actions;
- d) a TMA-REPORT indication primitive confirming the handle to the request;
- e) a TMA-REPORT indication primitive (successful complete transmission by random access or complete transmission by reserved access or stealing) and, if it is a response to either a AL-DATA-AR or AL-FINAL-AR PDU, the LLC shall start acknowledgement waiting timer T.252;
- f) a TMA-REPORT indication primitive (random access failure) and then:
  - i) for a CA MS, if the random access attempt was on a conforming  $\pi/4$ -DQPSK or D8PSK channel, the LLC shall inform the service user by a TL-REPORT indication primitive (failed transfer) and the LLC shall delete the TL-SDU from the sending buffer;
  - ii) for a CA MS, if the random access attempt was on a non-conforming  $\pi/4$ -DQPSK or D8PSK channel, or a QAM channel, the LLC may inform the service user by a TL-REPORT indication primitive (failed transfer) in which case the LLC shall delete the TL-SDU from the sending buffer;
  - iii) for a DA MS, the LLC may inform the service user by a TL-REPORT indication primitive (failed transfer) in which case the LLC shall delete the TL-SDU from the sending buffer;

NOTE 1: After receiving a TL-REPORT indication primitive reporting failed transfer (see b) and f) above) the service user should immediately either reset or disconnect the advanced link, which should be no more usable in the current state.

NOTE 2: In cases f)ii) and f)iii), if the LLC does not inform the service user by a TL-REPORT indication primitive (failed transfer), the LLC may continue to attempt to send the TL-SDU (using the current segmentation) and the service user need not reset or disconnect the advanced link. However the MS should not keep attempting random access excessively on the same channel after a random access failure.

PDU's from peer entity:

- g) an AL-ACK PDU either to acknowledge received segments and/or TL-SDUs or to indicate that the peer entity is capable to receive more data; refer to clause 22.3.3.2.3 for the actions on the acknowledgement;
- h) an AL-RNR PDU to acknowledge received TL-SDUs and/or segments and to indicate that the peer entity is currently not capable to receive more data; refer to flow control in clause 22.3.3.2.5.

NOTE 3: In this clause word segment is used instead of AL-DATA, AL-DATA-AR, AL-FINAL and AL-FINAL-AR PDU's, refer to segmentation in clause 22.3.3.2.1 and acknowledgement in clause 22.3.3.2.3 for selection of the correct PDU.

NOTE 4: The TL-SDU sending window is updated when the lowest SDU in the current window is completely acknowledged.

The MS may receive in the TMA-UNITDATA indication primitive carrying an AL-ACK or AL-RNR PDU the "Channel change response required" parameter set to "true"; then the MS shall pass it in a TL-REPORT indication primitive with the "Channel change handle" parameter to MLE.

### 22.3.3.2.7 Data reception from the peer entity (data receiving entity)

When advanced link LLC data receiving entity is ready for receiving data (in the state "AL\_RX\_READY"), it may receive:

Local indications:

- a) MAC-READY signal and then the LLC shall send the AL-ACK or AL-RNR PDU as appropriate, see later in this clause and in clause 22.3.3.2.3 for the acknowledgement procedure;

PDU's from the peer entity:

- b) AL-DATA or AL-FINAL PDU and then the LLC shall store the segment into the correct position for reassembling in the corresponding TL-SDU and shall check completeness and correctness of the received TL-SDU; and
  - if the TL-SDU is completely and correctly received (FCS matches) the LLC shall mark it received and ready for acknowledgement; and
  - if the number of the TL-SDU (N(S)) is the lowest SDU in the receiver window the LLC shall update both the lower and upper window boundary and deliver the received TL-SDU to the service user in a TL-DATA indication primitive; or

NOTE 1: If the next TL-SDU (or TL-SDUs) in the sequence have already been completely and correctly received, the LLC also delivers that TL-SDU (or those TL-SDUs) to the service user.

- if all segments of that TL-SDU are received, but the FCS calculation fails, then the LLC shall discard that SDU and mark that it needs to be re-transmitted.

- c) AL-DATA-AR or AL-FINAL-AR PDU and then the LLC shall store the segment into the correct position for reassembling in the corresponding TL-SDU and shall check completeness and correctness of the received TL-SDU; and
- if at least one new TL-SDU is completely and correctly received (FCS matches) the LLC shall mark it received and prepare either AL-ACK or AL-RNR PDU as defined in clauses 22.3.3.2.3 and 22.3.3.2.5, inform the formatter by the DATA\_IN\_BUFFER signal and, if the number of the TL-SDU (N(S)) is the lowest SDU in the receiver window, the LLC shall update the lower window boundary and deliver the received TL-SDU to the service user in a TL-DATA indication primitive;

NOTE 2: If the next TL-SDU (or TL-SDUs) in the sequence have already been completely and correctly received, the LLC also delivers that TL-SDU (or those TL-SDUs) to the service user.

NOTE 3: In case the BS LLC entity receives an AL-DATA(-AR) or AL-FINAL(-AR) PDU with a new TL-SDU number N(S), the BS LLC should indicate to the LLC service user that the reception of new TL-SDU has started by a TL-RECEIVE indication primitive.

- if all segments of that TL-SDU are received, but the FCS calculation fails, then the LLC shall discard that PDU and prepare either AL-ACK or AL-RNR PDU asking for re-transmission of that TL-SDU, with a possible bitmap of the unacknowledged segments in the other SDUs as defined in clauses 22.3.3.2.3 and 22.3.3.2.5 and inform the formatter by the DATA\_IN\_BUFFER signal;
- if no TL-SDU is received correctly, then the LLC shall mark the segment received and prepare either AL-ACK or AL-RNR PDU, with a bitmap of the unacknowledged segments as defined in clauses 22.3.3.2.3 and 22.3.3.2.5 and inform the formatter by the DATA\_IN\_BUFFER signal;

The LLC shall use PDU priority level = 5 and allow frame stealing for a response to an AL-DATA-AR or AL-FINAL-AR PDU (though in most cases neither of these parameters will actually be used in the MAC, since AL-ACK and AL-RNR PDUs are usually sent by reserved access).

indication from the service user:

- d) a FLOW-NOT-READY signal and then the LLC shall prepare an AL-RNR PDU, with a possible bitmap of the unacknowledged segments in the received SDUs and inform the formatter by the DATA\_IN\_BUFFER signal;
- e) a FLOW-READY signal and then the LLC shall prepare an AL-ACK PDU, with a possible bitmap of the unacknowledged segments in the received SDUs and inform the formatter by the DATA\_IN\_BUFFER signal, refer to flow control in clause 22.3.3.2.5.

NOTE 4: The data receiving process delivers TL-SDUs in the sequence defined by the N(S).

NOTE 5: If it receives any of the data transfer PDUs (AL-DATA, AL-DATA-AR, AL-FINAL or AL-FINAL-AR), when the corresponding advanced link is no more in "RX\_READY" state, then the PDU will be discarded in this model by the formatter without any further actions.

NOTE 6: When the LLC data receiving entity has completely and correctly received a TL-SDU, and if the number of the TL-SDU is the lowest in the receiver window, then the LLC updates the lower window boundary and delivers the received TL-SDU to the service user. However, even when the LLC has sent an acknowledgement for the correctly received TL-SDU, that acknowledgement may not have been received by the data sending entity. Therefore the LLC may still receive AL-DATA(-AR) and AL-FINAL(-AR) PDUs for the N.272 TL-SDUs below the current receiver window. If this occurs, the data receiving LLC should discard the received segment(s) but should send an acknowledgement to indicate that the TL-SDU has been correctly received. If there is space within the MAC block, the data receiving LLC should also send acknowledgements indicating that the TL-SDU has been correctly received for any more recent TL-SDUs below the current receiver window.

NOTE 7: In the LLC advanced link protocol the data sending entity should retry transmission in case it does not receive an expected acknowledgement since the protocol actions taken in case of a transmission failure of an AL-ACK or AL-RNR PDU are not defined in the present document.

The MS may receive in the TMA-UNITDATA indication primitive carrying an AL-DATA(-AR) and AL-FINAL(-AR) PDU the "Channel change response required" parameter set to "true"; then the MS shall pass it in a TL-REPORT indication primitive or if available in the corresponding TL-DATA indication primitive with the "Channel change handle" parameter to MLE.

### 22.3.3.2a Acknowledged data transfer on an extended advanced link

For acknowledged data transfer on an extended advanced link, the procedures described in clause 22.3.3.2 shall apply for that extended advanced link with the following differences:

- i) PDUs AL-X-DATA, AL-X-DATA-AR, AL-X-FINAL, AL-X-FINAL-AR, AL-X-ACK and AL-X-RNR shall be used instead of PDUs AL-DATA, AL-DATA-AR, AL-FINAL, AL-FINAL-AR, AL-ACK and AL-RNR respectively.
- ii) The advanced link number shall be included in each PDU.
- iii) The TL-SDU sequence number shall be a five-bit number incremented in a modulo manner with each transmitted TL-SDU (instead of a three-bit number).
- iv) The window size N.272 may be larger for an extended advanced link than for the original advanced link.

NOTE 1: As in clause 22.3.3.2.3: when acknowledging TL-SDUs, if the acknowledgement blocks do not fit within one MAC block, the data receiving entity may send multiple AL-X-ACK (or AL-X-RNR) PDUs.

However, if the data receiving entity wishes to send more than one acknowledgement block which refers to the same TL-SDU, those acknowledgement blocks should be included within the same AL-X-ACK (or AL-X-RNR) PDU, using fragmentation if necessary; the data receiving entity is not permitted to divide acknowledgement blocks which refer to the same TL-SDU between multiple AL-X-ACK (or AL-X-RNR) PDUs.

- v) Use of the FCS is optional on an extended advanced link, so:
  - the data sending entity only calculates the FCS and appends it to the TL-SDU (see clause 22.3.3.2.6) if requested by the service user in the TL-DATA request primitive;
  - if the AL-X-FINAL or AL-X-FINAL-AR PDU indicates that the FCS is not present then, when the data receiving entity is re-assembling the TL-SDU (see clause 22.3.3.2.7), it shall check only for completeness of the TL-SDU instead of checking for completeness and correctness.
- vi) The LLC header of the AL-X-FINAL and AL-X-FINAL-AR PDU is one bit longer than the LLC header of the AL-X-DATA and AL-X-DATA-AR PDU. Therefore there are occasional cases when the last part of the TL-SDU (and FCS when used) just fits within an AL-X-DATA or AL-X-DATA-AR PDU but would not fit within an AL-X-FINAL or AL-X-FINAL-AR PDU. In these cases, the data sending LLC entity should send the last part of the TL-SDU (and FCS when used) within an AL-X-DATA or AL-X-DATA-AR PDU and then send an empty AL-X-FINAL or AL-X-FINAL-AR PDU (i.e. containing no information after the FCS flag) to complete the TL-SDU transmission.

Therefore the data receiving LLC entity may occasionally receive an AL-X-FINAL or AL-X-FINAL-AR PDU containing no information after the FCS flag. The AL-X-FINAL or AL-X-FINAL-AR PDU indicates the termination of the TL-SDU so, when all the other segments have been received, those other segments comprise the complete TL-SDU (and FCS when used).

For the purposes of the acknowledgement protocol, both the data sending entity and the data receiving entity shall process the empty AL-X-FINAL or AL-X-FINAL-AR PDU using the usual procedures for an AL-X-FINAL or AL-X-FINAL-AR PDU. For example, when required by the usual procedures, the data receiving entity shall include a bit in the acknowledgement bit map to indicate successful reception of the AL-X-FINAL or AL-X-FINAL-AR PDU.

- vii) On a D8PSK or QAM channel, link adaptation feedback information may be included within AL-X-ACK and AL-X-RNR PDUs; see clause 22.3.1.7.3.
- viii) For the extended advanced link, the data receiving entity may include an acknowledgement block indicating "All SDUs prior to this SDU correctly received". When included, this acknowledgement block shall be the first acknowledgement block in the AL-X-ACK (or AL-X-RNR) PDU; see clause 22.3.3.2.3.
- ix) For the extended advanced link, the data receiving entity shall select the acknowledgement blocks to be sent in an AL-X-ACK (or AL-X-RNR) PDU obeying the following rules:
  - a) the acknowledgement blocks shall be sorted with acknowledgement blocks for the oldest TL-SDUs being acknowledged first (see note 2);

- b) the acknowledgement blocks shall be for consecutive TL-SDU numbers (see note 2), except when acknowledgement blocks may be omitted as indicated in point d) below;
- c) if an acknowledgement for a TL-SDU cannot be sent using a single acknowledgement block, the data receiving entity shall include the necessary multiple acknowledgement blocks for the TL-SDU in preference to including acknowledgement information for the next TL-SDU(s);
- d) the data receiving entity may choose to leave out acknowledgement blocks for TL-SDUs that have been correctly received if another acknowledgement block follows in the AL-X-ACK (or AL-X-RNR). The data transmitting entity shall consider such TL-SDUs as "SDU correctly received".

NOTE 2: The acknowledgement block TL-SDU numbers are sorted and consecutive modulo 32. If the data receiving entity wishes to include an acknowledgement block for TL-SDUs 0, 1, 30 and 31, the correct order is: 30, 31, 0, 1.

NOTE 3: The above rules only apply within an AL-X-ACK (or AL-X-RNR). If the data transmitting entity receives two AL-X-ACKs (or AL-X-RNRs) with a gap in TL-SDU number between the TL-SDUs being acknowledged in the first and second AL-X-ACK (or AL-X-RNR), this gap conveys no information about the TL-SDUs in the gap. The data transmitting entity cannot consider the TL-SDUs in the gap as being acknowledged as a result of receiving the two AL-X-ACKs (or AL-X-RNRs).

EXAMPLE: If the data transmitting entity receives an AL-X-ACK including acknowledgement blocks for TL-SDUs 2 and 5, followed by a second AL-X-ACK including acknowledgement blocks for TL-SDUs 7 and 9, then this indicates that TL-SDUs 3, 4, and 8 have been correctly received, but indicates nothing about TL-SDU 6.

See clause 22.3.3.2.3.

- x) When the data receiving entity receives AL-X-DATA(-AR) or AL-X-FINAL(-AR) PDUs for the N.272 TL-SDUs below the current receiver window, instead of sending acknowledgements for each TL-SDU below the current receiver window, the data receiving entity should send an acknowledgement block indicating "All SDUs prior to this SDU correctly received" for the oldest TL-SDU which is not completely received or for the newest completely received TL-SDU in case there are no partially received TL-SDUs in the data receiving entity buffers; see note 6, clause 22.3.3.2.7.

If an MS is using more than one advanced link, the data transfer procedures for each advanced link operate independently of the data transfer procedures for the other advanced link(s).

### 22.3.3.3 Release of acknowledged service advanced link

#### 22.3.3.3.0 General

In the advanced link the end of the transfer shall be notified by AL-DISC PDU with reason "close". In the acknowledged data transfer the disconnection shall be confirmed by sending a AL-DISC PDU with reason "success". Disconnection may occur at any time. When the receiving entity recognizes a disconnect it shall delete all partially received TL-SDUs for that advanced link.

#### 22.3.3.3.1 Actions on TL-DISCONNECT request primitive (MS sending entity)

Upon reception of a TL-DISCONNECT request primitive in state WAIT\_OUT\_CONNECT or CONNECTED, the LLC shall:

- i) prepare an AL-DISC PDU with reason "Close" and inform the formatter by DATA\_IN\_BUFFER signal;
- ii) set re-try counter to allow the maximum number of connection disconnect retries N.263;
- iii) cease all sending and receiving any data and discard all TL-SDUs waiting for sending on this advanced link or which are partially received on this advanced link and start to wait in "WAIT\_DISCONNECT" state.

In the "WAIT\_DISCONNECT" state the LLC may receive:

Local indications:

- a) a MAC-READY signal and then the LLC shall issue the AL-DISC PDU to the formatter;
- b) a TMA-REPORT indication primitive (successful complete transmission by random access or complete transmission by reserved access or by stealing) and then the LLC shall start the disconnection waiting timer T.263;
- c) a TMA-REPORT indication primitive (random access failure) and then the LLC shall inform the service user by a TL-DISCONNECT confirm primitive (random access failure) and go into the "IDLE" state for this advanced link;
- d) an indication of the expiry of the disconnection waiting timer T.263 and:
  - if more retries (N.263) are available, then the LLC shall issue the previous AL-DISC PDU into the transmission buffer and inform formatter by the DATA\_IN\_BUFFER signal;
  - if all retries (N.263) are used, then the LLC shall inform the service user by a TL-DISCONNECT confirm primitive (disconnection failure) and go into the "IDLE" state for this advanced link.

A PDU from the peer entity:

- e) an AL-DISC PDU with reason "Success", then the LLC shall inform the service user by a TL-DISCONNECT confirm primitive and go into the "IDLE" state for this advanced link;
- f) an AL-DISC PDU with reason "Close", then the LLC shall deliver an AL-DISC PDU with reason "Success" to the formatter as a response to the next MAC-READY signal and go into the "IDLE" state for this advanced link.

#### 22.3.3.3.2 Actions on AL-DISC PDU reception (MS receiving entity)

While being ready for data transfer the advanced link LLC may receive:

A PDU from the peer entity:

- a) an AL-DISC PDU with reason "Close" and then:
  - i) the LLC shall stop sending and receiving any data and discard both TL-SDUs waiting for sending on this advanced link and TL-SDUs which are partially received or fully received on this advanced link;
  - ii) prepare an AL-DISC PDU with a reason "Success" and inform the formatter by the DATA\_IN\_BUFFER signal;
  - iii) indicate to the service user the removal of the advanced link using a TL-DISCONNECT indication primitive "incoming disconnection";

Local indications after preparing an AL-DISC PDU:

- b) a MAC-READY signal and then the LLC shall issue the AL-DISC PDU to the formatter;
- c) a TMA-REPORT indication primitive (successful complete transmission by random access or complete transmission by reserved access or by stealing) and then the LLC shall go into the "IDLE" state for this advanced link;
- d) a TMA-REPORT indication primitive (random access failure) and then the LLC shall go into the "IDLE" state for this advanced link.

When the LLC receives in the "IDLE" state an AL-DISC PDU with reason "Close", the LLC shall deliver an AL-DISC PDU with reason "Success" to the formatter as a response to the next MAC-READY signal.

NOTE: An MS may receive an AL-DISC PDU also in other states of the LLC protocol, refer to advanced link establishment actions.

### 22.3.3.4 Abnormal release of advanced link

While in any state the advanced link LLC may receive:

- a) a TL-RELEASE request primitive from the service user and then the LLC shall close the advanced link without any signalling with the peer entity and go to the "IDLE" state for this advanced link;
- b) a TMA-RELEASE indication primitive and then the LLC shall close the advanced link(s) corresponding to this endpoint identifier without any signalling with the peer entity, indicate link disconnection to the service user by TL-DISCONNECT indication primitive(s) with a reason "local disconnection" and go to the "IDLE" state for that advanced link (or those advanced links).

### 22.3.3.5 LLC reconnection of acknowledged service advanced link

A request for the LLC to reconnect an advanced link shall be notified using the AL-RECONNECT PDU with a reconnect report "propose". A successful reconnection of the advanced link by the LLC shall be confirmed by the reception of an AL-RECONNECT PDU with the reconnect report "accept" and unsuccessful reconnection by the reception of an AL-RECONNECT PDU with the reconnect report "reject".

Upon reception of a TL-RECONNECT request primitive when in state "CONNECTED" for that advanced link, the LLC shall:

- i) prepare an AL-RECONNECT PDU with reason "propose" and inform the formatter by DATA\_IN\_BUFFER signal;
- ii) set re-try counter to allow the maximum number of reconnect retries N.265;
- iii) cease all sending and receiving any data and start to wait in "WAIT\_RECONNECT" state.

In the "WAIT\_RECONNECT" state the LLC may receive:

Local indications:

- a) a MAC-READY signal and then the LLC shall issue the AL-RECONNECT PDU to the formatter;
- b) a TMA-REPORT indication primitive (successful complete transmission by random access or complete transmission by reserved access or by stealing) and then the LLC shall start the reconnection waiting timer T.265;
- c) a TMA-REPORT indication primitive (random access failure) and then the LLC shall inform the service user by a TL-RECONNECT confirm primitive with the reconnection result set to "random access failure";
- d) an indication of the expiry of the reconnection waiting timer T.265, and:
  - if more retries (N.265) are available, then the LLC shall issue the previous AL-RECONNECT PDU into the transmission buffer and inform formatter by the DATA\_IN\_BUFFER signal;
  - if all retries (N.265) are used, then the LLC shall inform the service user by a TL-RECONNECT confirm primitive with the reconnection result set to "reconnection failure".

A PDU from the peer entity:

- e) an AL-RECONNECT PDU with reason "accept", then the LLC shall inform the service user by a TL-RECONNECT confirm primitive with the reconnection result set to "success" and go into the "CONNECTED" state for this advanced link, accept the channel change, if any, by issuing a TMC-CONFIGURE request primitive to MAC with the parameter channel change accepted set to "accept" and continue to transmit and receive TL-SDU segments without resetting the advanced link;
- f) an AL-RECONNECT PDU with reason "reject", then the LLC shall inform the service user by a TL-RECONNECT confirm primitive with the reconnection result set to "reject" and accept the channel change, if any, by issuing a TMC-CONFIGURE request primitive to MAC with the parameter channel change accepted set to "accept".

## 22.3.4 Advanced link procedures for unacknowledged service

### 22.3.4.0 General

The unacknowledged service uses the same mechanisms for sequencing, segmentation and re-assembling as the acknowledged service (see clauses 22.3.3.2.1 and 22.3.3.2.2). The window size for TL-SDU in unacknowledged service N.281 defines how many TL-SDUs may be in transit at the same time. The numbering of TL-SDUs N(S), contrary to the acknowledged service, may start at any value.

### 22.3.4.1 Advanced link unacknowledged service establishment

The BS should establish the unacknowledged service before it starts to send data.

The BS should start unacknowledged data transfer by sending one or more AL-SETUP PDUs. During unacknowledged data transfer the BS may repeat the AL-SETUP PDU using the current value for the TL-SDU number N(S) to re-synchronize receiving MSs. The TL-SDU numbering may start at any value to allow re-setting of an unacknowledged service without re-setting the TL-SDU window position. After the reception of an AL-SETUP PDU the TL-SDU window lower edge shall be the TL-SDU number N(S) and the upper edge shall be  $N(S) + N.281 - 1$ . (N.281 is the window size for TL-SDUs in the unacknowledged service.) After sending an AL-SETUP PDU the BS should not repeat any TL-SDU or segments of those having a TL-SDU sequence number lower than the one (N(S)) indicated in the AL-SETUP PDU.

**NOTE:** If the BS establishes an advanced link for the unacknowledged service to carry TL-SDUs with a maximum length of 4 096 octets then, in the case of a 25 kHz QAM channel, the BS needs to assign an event label for that address for use on that channel; see clause 23.4.1.2.3.1. This is needed in order to enable unique segment numbering with the eight-bit segment sequence number.

### 22.3.4.2 Reception of unacknowledged service data on the original advanced link

The LLC MS entity may receive at any state:

- a) an AL-SETUP PDU for unacknowledged information reception and then the LLC shall empty possible current buffer for this advanced link, prepare a new buffer for data reception, inform the service user by a TL-CONNECT indication primitive (unacknowledged service) and start to wait for data in the state "AL\_UNACK\_READY";
- b) an AL-DISC PDU and then the LLC shall discard all partially received TL-SDUs on this advanced link and may deliver a TL-DISCONNECT indication primitive to the service user.

If the LLC MS entity is in state AL\_UNACK\_READY for an original unacknowledged advanced link and it receives an AL-SETUP PDU for an original unacknowledged advanced link for that address but with a different advanced link number, the LLC shall empty possible current buffer for the existing original advanced link, prepare a new buffer for data reception, inform the service user by a TL-CONNECT indication primitive (unacknowledged service) and wait for data in the state "AL\_UNACK\_READY".

**NOTE 1:** If the LLC MS entity does not support the augmented AL-SETUP PDU and it receives an AL-SETUP PDU for the unacknowledged service (i.e. "advanced link service" element set to 0) with the "TL-SDU window size" element set to  $00_2$ , it should discard the AL-SETUP PDU without performing any of the actions in the above paragraph or in procedure a).

While in the "AL\_UNACK\_READY" state the MS LLC may receive an AL-UDATA PDU or an AL-UFINAL PDU; and:

- if the corresponding TL-SDU is not earlier delivered to the service user, then the LLC shall store the segment into correct position of the relevant TL-SDU as indicated by N(S) and S(S) elements respectively; and
- if a TL-SDU is now completely and correctly received, then the LLC shall deliver the TL-SDU to the service user in a TL-UNITDATA indication primitive and mark the TL-SDU as received.

**NOTE 2:** The MS LLC may deliver the received TL-SDUs out of sequence.

**NOTE 3:** The advanced link protocol allows suppression of received duplicates.

Each time the LLC receives an AL-UDATA or an AL-UFINAL PDU the LLC shall upgrade the receiving window upper edge to the received N(S) if it is higher than the current upper edge and calculate a new lower edge. The LLC shall then check if there are any partially received TL-SDUs, which have TL-SDU number outside the new receiving window and then the LLC shall discard those partially received SDUs.

The advanced link number is not included in the AL-UDATA and AL-UFINAL PDUs. The advanced link number in the AL-UDATA and AL-UFINAL PDUs shall be implicitly assumed to be as indicated in the AL-SETUP PDU for the original unacknowledged advanced link.

NOTE 4: An AL-SETUP PDU for unacknowledged information reception (or an AL-UDATA or AL-UFINAL PDU) may be sent in a group addressed MAC PDU that contains a channel allocation. If the MS-MAC requires instruction on whether to accept the channel allocation, then it sets the "channel change response required" parameter to "true" in the TMA-UNITDATA indication primitive. If the MS decides to accept the channel allocation then the higher layers should issue a TMC-CONFIGURE request primitive to the MAC containing the "channel change handle" parameter and "channel change accepted" parameter set to "accept". However, if a channel change is not acceptable, a TMC-CONFIGURE request primitive should be issued with the "channel change parameter" set to "reject".

#### 22.3.4.2a Reception of unacknowledged service data on an extended advanced link

For reception of unacknowledged service data on an extended advanced link, the procedures described in clause 22.3.4.2 shall apply for that extended advanced link with the following differences:

- i) PDUs AL-X-UDATA and AL-X-UFINAL shall be used instead of PDUs AL-UDATA and AL-X-UFINAL respectively.
- ii) The advanced link number is included in each PDU.
- iii) The window size N.281 may be larger for an extended advanced link than for the original advanced link.
- iv) Use of the FCS is optional on an extended advanced link so, if the AL-X-UFINAL PDU indicates that the FCS is not present, the LLC MS entity shall deliver the TL-SDU to the service user when it has received the complete TL-SDU (without checking for correctness).
- v) The LLC header of the AL-X-UFINAL PDU is one bit longer than the LLC header of the AL-X-UDATA PDU. Therefore there are occasional cases when the last part of the TL-SDU (and FCS when used) just fits within an AL-X-UDATA PDU but would not fit within an AL-X-UFINAL PDU. In these cases, the BS LLC may send the last part of the TL-SDU (and FCS when used) within an AL-X-UDATA PDU and then send an empty AL-X-UFINAL PDU (i.e. containing no information after the FCS flag) to complete the TL-SDU transmission.

Therefore the LLC MS entity may occasionally receive an AL-X-UFINAL PDU containing no information after the FCS flag. The AL-X-UFINAL PDU indicates the termination of the TL-SDU so, when all the other segments have been received, those other segments comprise the complete TL-SDU (and FCS when used).

If an MS is receiving more than one unacknowledged advanced link, the procedures for each advanced link operate independently of the procedures for the other advanced link(s).

#### 22.3.4.3 Sliding SDU window in unacknowledged service

The BS LLC should send unacknowledged data using a TL-SDU window size of 1 to the maximum N.281. This means that the BS LLC may transmit with any repetitions up to N.281 different TL-SDUs at any time. The BS LLC may start to send a new TL-SDU if its window is not currently full. If the BS LLC wishes to send a new TL-SDU when its window is full then it may either:

- wait until all repetitions of the oldest TL-SDU in the window are completed and then start to send the new TL-SDU; or
- cease transmission of the oldest TL-SDU in the window (including any repetitions) and start to send the new TL-SDU.

The BS LLC indicates the TL-SDU window size at the establishment of the advanced link by sending one or more AL-SETUP PDUs.

NOTE: The window size N.281 may be larger for an extended advanced link than for the original advanced link.

#### 22.3.4.4 Disconnection of unacknowledged data transfer

The BS may disconnect an unacknowledged service by sending one or more AL-DISC PDUs. When the MS receives an AL-DISC PDU it shall discard all partially received TL-SDUs on this advanced link and cease reception of all AL-UDATA PDUs (in the case of the original advanced link) or AL-X-UDATA PDUs (in the case of an extended advanced link).

#### 22.3.5 Channel change request handling

The MAC layer may issue with TMA-UNITDATA indication primitive "channel change response required" parameter with value "true" indicating that an upper layer shall provide a response to MAC layer.

Upon reception of a "channel change response required" in a TMA-UNITDATA indication primitive:

- if the TMA-UNITDATA indication primitive contains a TL-SDU, the LLC shall pass the request to MLE in the corresponding TL-UNITDATA indication primitive;
- if the TMA-UNITDATA indication primitive contains no TL-SDU and the endpoint identifier refers to an advanced link service MAC resource, the LLC may pass the request to the MLE in a TL-REPORT indication primitive or decide to accept or reject the request based on the other LLC services and their importance;

NOTE 1: The same endpoint identifier refers to the advanced link(s) and to the related basic link when advanced link(s) exist.

NOTE 2: The service importance determination at the LLC is outside the scope of the present document.

- if the TMA-UNITDATA indication primitive contains no TM-SDU and the endpoint identifier refers only to the basic link service MAC resource and there is only a single user of LLC services, the LLC shall pass the request to the MLE in a TL-REPORT indication primitive;

NOTE 3: How LLC knows the number of service users is outside the scope of the present document.

- in other cases the actions are outside the scope of the present document.

The MAC layer may issue TMC-CONFIGURE indication primitive due to various resource conflicts. Upon reception of a TMC-CONFIGURE indication primitive with reason "loss of physical resources", the LLC shall indicate to the MLE in a TL-CONFIGURE indication primitive the loss of physical resources for that endpoint identifier. Also:

- if the TMC-CONFIGURE indication primitive is related to an advanced link and the MS supports advanced link continuation and there are one or more uncompleted TL-SDUs in the send or reception buffer, the LLC shall retain the advanced link for a potential continuation without sending any new TMA-UNITDATA request primitives for that advanced link;

NOTE 4: Only SNDCP layer can support advanced link continuation by the MS, refer to clause 28, and any upper layers may disconnect locally the advanced link by a TL-RELEASE request primitive. However, use of the advanced link may continue if the LLC receives data from the BS on the retained advanced link.

- if the TMC-CONFIGURE indication primitive is related to an advanced link and the MS supports advanced link continuation but there are no uncompleted TL-SDUs in the send or reception buffer, the LLC shall either:
  - locally disconnect the advanced link; or
  - retain the advanced link for a potential continuation without sending any new TMA-UNITDATA request primitives for that advanced link;
- if the TMC-CONFIGURE indication primitive is related to an advanced link (or links) and the MS does not support advanced link continuation, the LLC shall locally disconnect the advanced link (or links).

Upon reception of a TMC-CONFIGURE indication primitive with reason "gain of physical resources" the LLC may continue to use the indicated MAC resource.

NOTE 5: Before LLC can use the resource for a retained advanced link, the continuation of the link is first invoked by upper layer actions (refer to clause 28) or the LLC receives data from the BS on the retained advanced link.

The MAC layer may also issue a TMA-RELEASE indication primitive due to loss of radio resources, when the loss is detected locally without a signalling from BS. The LLC behaviour is defined in clause 22.3.3.4.

## 22.3.6 Activity handling

On reception of a TL-CONFIGURE request primitive and the MLE activity indicator parameter has sleep mode value "stay alive" the LLC shall send a TMC-CONFIGURE request primitive with MLE activity indicator parameter set to value "stay alive".

On reception of a TL-CONFIGURE request primitive and the MLE activity indicator parameter has sleep mode value "sleep permitted" the LLC shall check whether an advanced link is in advanced link establishment or reset phase, see clause 22.3.3.1, LLC advanced link reconnection phase, see clause 22.3.3.5 or in advanced link disconnection phase, see clause 22.3.3.3. If no advanced link is in any of those states, then the LLC shall send a TMC-CONFIGURE request primitive with MLE activity indicator parameter set to value "sleep permitted".

Upon the start of an advanced link establishment or reset phase, see clause 22.3.3.1, LLC advanced link reconnection phase, see clause 22.3.3.5 or advanced link disconnection phase, see clause 22.3.3.3, the LLC shall send a TMC-CONFIGURE request primitive with MLE activity indicator parameter set to value "stay alive", if LLC has not yet informed MAC to stay alive.

When all ongoing advanced link establishment or reset, LLC advanced link reconnection or advanced link disconnection phases have been completed, the LLC shall send a TMC-CONFIGURE request primitive with MLE activity indicator parameter set to value "sleep permitted" unless the MLE has asked in a TL-CONFIGURE request primitive to "stay alive".

NOTE: The MLE activity indicator parameter is used by the MS-MAC in its procedure to decide when it may use the energy economy sleeping cycle (see clause 23.7.6) or the dual watch reception cycle (see clause 23.7.7) or part-time reception on a multi-slot MCCH-Q (see clause 23.7.8).

## 22.3.7 Layer 2 signalling procedures

### 22.3.7.0 General

The layer 2 signalling PDUs carry various types of general signalling information relating to layer 2 functions - either LLC or MAC functions. For convenience, the layer 2 signalling PDUs are treated as LLC PDUs in the PDU structures.

In the present document, the layer 2 signalling PDUs are used only for MAC functions.

The LLC procedures in an MS for layer 2 signalling are described in the following clauses.

### 22.3.7.1 Layer 2 signalling procedures (sending entity)

During sending of layer 2 signalling data corresponding to a MAC function, the LLC may receive:

- a) a TLE-UNITDATA request primitive from the MAC and then the LLC shall:
  - store the message in PDU priority order into the sending buffer for sending  $N.293 + 1$  times; and
  - indicate new data in the sending buffer to the formatter using the DATA\_IN\_BUFFER signal;
- b) a MAC-READY signal from the formatter and then the LLC shall form the highest priority layer 2 signalling PDU and issue it to the formatter;

NOTE 1: The formatter delivers the PDU to the MAC using a TMA-UNITDATA request primitive.

- c) a TLE-CANCEL request primitive from the MAC and then:
- if the LLC has already transferred the message to the MAC, it shall issue a TMA-CANCEL request primitive; on receipt of a TMA-REPORT indication primitive indicating the result of the cancellation, the LLC shall note whether the TM-SDU was completely sent;
  - the LLC shall inform the MAC whether the layer 2 signalling message was completely sent at least once, using a TLE-REPORT indication primitive; and
  - the LLC shall delete the message from the sending buffer;
- d) a TMA-REPORT indication primitive confirming the handle to the request;
- e) a TMA-REPORT indication primitive (first complete transmission by random access), and then the LLC shall inform the MAC that the message has been completely transmitted once using a TLE-REPORT indication primitive;
- f) a TMA-REPORT indication primitive (successful complete transmission by random access), and then the LLC shall:
- inform the MAC that the transfer of the layer 2 signalling message was completed by random access, using a TLE-REPORT indication primitive; and
  - delete the message from the sending buffer;
- g) a TMA-REPORT indication primitive (complete transmission by stealing or by reserved access), and then, if that message has now been completely transmitted once, the LLC shall inform the MAC using a TLE-REPORT indication primitive; also, if the message has now been completely transmitted  $N.293 + 1$  times, the LLC shall:
- inform the MAC that the transfer of the layer 2 signalling message was completed, using a TLE-REPORT indication primitive; and
  - delete the message from the sending buffer;
- h) a TMA-REPORT indication primitive (failure of fragmentation process) and then:
- if  $N.293 > 0$ , the LLC shall try to re-send the layer 2 signalling message so that there shall be at maximum  $N.293 + 1$  failed transmissions (in addition to the  $N.293 + 1$  complete transmissions); if there have not been  $N.293 + 1$  complete transmissions when the maximum number of failed transmissions  $N.293 + 1$  has been reached, then the LLC shall:
    - inform the MAC that the transfer of the layer 2 signalling message failed, using a TLE-REPORT indication primitive; and
    - delete the message from the sending buffer;
  - if  $N.293 = 0$ , the LLC shall try to re-send the layer 2 signalling message so that there shall be at maximum two failed transmissions (or the message has been completely transmitted); if there has not been one complete transmission when the maximum of two failed transmissions has been reached, then the LLC shall:
    - inform the MAC that the transfer of the layer 2 signalling message failed, using a TLE-REPORT indication primitive; and
    - delete the message from the sending buffer;
- i) a TMA-REPORT indication primitive (random access failure) and then the LLC shall:
- inform the MAC that the transfer of the layer 2 signalling message failed, using a TLE-REPORT indication primitive; and
  - delete the message from the sending buffer.

- NOTE 2: The MAC may indicate the required number of repetitions (i.e. N.293) in the TLE-UNITDATA request primitive, in which case that value is applied for transmission of the message. If the MAC does not indicate the required number of repetitions, the value of N.293 chosen by the MS designer is used (see annex A).
- NOTE 3: The MS may send more than one layer 2 signalling message in one MAC block (using MAC PDU association).
- NOTE 4: For  $N.293 > 0$ , the MS should not send the same layer 2 signalling message more than once in one MAC block. The layer 2 signalling service does not guarantee in-order delivery at the receiving entity. Therefore, in order to use the capacity of MAC blocks by PDU association, the MS may interleave retransmissions of multiple layer 2 signalling messages.
- NOTE 5: In the DATA\_IN\_BUFFER signal, the LLC may include all outstanding layer 2 signalling messages as outstanding data ready to be sent, so that the MAC can indicate a reservation requirement for that data.
- NOTE 6: When appropriate, the information in an L2-LINK-FEEDBACK-INFO PDU may be combined into an AL-X-ACK or AL-X-RNR PDU; or the information in an L2-LINK-FEEDBACK-INFO and L2-DATA-PRIORITY PDU may be combined as an L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU. According to the protocol model, the combining is performed as described in clause 22.3.1.7.3.2.

### 22.3.7.2 Layer 2 signalling procedures (receiving entity)

Upon reception of a layer 2 signalling PDU from the formatter:

- in the case of an L2-SCHEDULE-SYNC or L2-LINK-FEEDBACK-CONTROL or L2-LINK-FEEDBACK-INFO PDU, the LLC shall inform the MAC of the contents of the PDU using a TLE-UNITDATA indication primitive.

- NOTE 1: In the present document, the L2-SCHEDULE-SYNC, L2-LINK-FEEDBACK-CONTROL and L2-LINK-FEEDBACK-INFO PDUs are the only types of layer 2 signalling PDU that the MS expects to receive.
- NOTE 2: The layer 2 signalling protocol does not suppress received duplicates.
- NOTE 3: The formatter receives the PDU from the MAC in a TMA-UNITDATA indication primitive.
- NOTE 4: The MS may also receive link adaptation feedback information within an AL-X-ACK or AL-X-RNR PDU. According to the protocol model, the formatter generates an L2-LINK-FEEDBACK-INFO PDU containing the link adaptation feedback information, as described in clause 22.3.1.7.3.1.

---

## 23 MAC protocol

### 23.0 General

This clause describes the V+D air interface layer 2 MAC protocol. It defines the operation of the MAC layer in the MS and includes some corresponding rules for the operation of the BS. However, the exact rules for how the BS allocates resources to MSs are outside the scope of the present document.

See ETSI EN 300 392-1 [6], clause 6 for the general architecture and a description of all layers including the functionality of the MAC sub-layer (see clause 19 for the architecture of the DLL). MAC timers and constants are defined in annex B.

### 23.1 MAC services

#### 23.1.1 Functions of MAC

In the protocol model, internal communication between the LLC and the MAC uses three SAPs TMA-SAP, TMB-SAP and TMC-SAP for services provided by the MAC to the LLC, corresponding to signalling, broadcast and layer management functions respectively. A fourth SAP, the TMD-SAP, supports traffic in circuit mode; this service is offered directly from the MAC to the U-plane application (e.g. the CODEC).

Internal communication between the LLC and the MAC also uses a further SAP, TLE-SAP, for the layer 2 signalling service provided by the LLC to the MAC.

The MAC itself is divided into two sub-layers, i.e. the upper and lower MAC.

The lower MAC performs the channel coding, interleaving and scrambling, as described in clause 8. The upper MAC performs the other MAC protocol functions and is described within clause 23. Unless specified otherwise, references to "the MAC" throughout clause 23 mean the upper MAC.

The principal functions of the upper MAC are as follows:

- frame and multiframe synchronization;
- multiplexing/de-multiplexing of the logical channels;
- radio path establishment and channel allocation (for common control channels and for assigned channels);
- address management for the layer 2 address (the source address for the uplink, the destination address for the downlink);
- fragmentation of long messages received from the LLC (subdividing the LLC message between more than one MAC block);
- association of short messages received from the LLC (enabling more than one message to be sent within one MAC block);
- management of power control;
- the random access procedure (contention control);
- granting and use of reserved slots i.e. non-contentious slots reserved by the BS for one MS to send signalling message(s);
- path loss calculation: surveillance of the serving cell, monitoring and scanning of adjacent cells, monitoring of irregular channels and assessment of channel classes;
- energy economy, part-time reception and napping operation;
- short-term data priority procedure;

- link adaptation on D8PSK and QAM channels;
- providing service to circuit mode applications (e.g. speech CODEC or circuit mode data) on  $\pi/4$ -DQPSK channels;
- stealing from the traffic channel capacity, when required, to send signalling messages on  $\pi/4$ -DQPSK channels.

## 23.1.2 Service primitives

### 23.1.2.0 General

The MAC protocol is described in terms of primitives and valid sequences of actions resulting from those primitives. Refer to clause 20 for a detailed description of the service primitives.

The use of primitives throughout clause 23 refers to the protocol definition, but does not imply any specific implementation. The MAC boundary, as for other internal boundaries, is defined to clarify the protocol description. The word "shall" is used to describe the SAPs and primitives for traceability reasons in the protocol model, but those SAPs and primitives are not testable.

### 23.1.2.1 Services at the TMA-SAP

#### 23.1.2.1.0 General

The TMA-SAP shall be used for the transmission of signalling and packet data information over the air interface. Service data units, TM-SDUs, shall be transferred to and from the LLC using the TMA-UNITDATA primitive. (The TM-SDU is the LLC PDU, including the LLC header and optional FCS.)

- The TMA-UNITDATA request primitive from LLC to MAC shall be used when the LLC wishes to send data to the peer entity.
- The TMA-UNITDATA indication primitive from MAC to LLC shall be used to deliver data received from the peer entity.

The MAC in the MS (MS-MAC) shall report the progress of a request procedure locally to the LLC using the TMA-REPORT indication primitive. The LLC may abort a TMA-UNITDATA request using the TMA-CANCEL request primitive.

The random access protocol is generally needed when the MS sends a message to initiate a call or transaction. However, when an MS is required to send a solicited message or when it has further signalling to send after the initial access, the BS may reserve slots for that particular MS. This enables a higher channel throughput to be achieved. Also the MS at SNDCP level may negotiate that the BS will grant reserved capacity with a specified repetition period (and specified timing accuracy), in order to support an application which requires regular transmissions of bursts of data; this is called scheduled access. When the schedule becomes active, the BS should reserve slots for that MS without the MS needing to use random access.

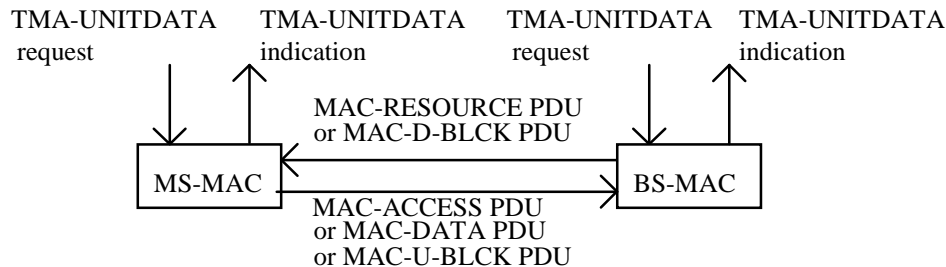

On a control channel, MSs may transmit only by random access or reserved access. Whereas, during a circuit mode call, the transmitting MS may "steal" from the traffic channel capacity to send signalling messages.

The signalling service offered by the MS-MAC to the LLC shall be an unacknowledged service in the case of non-contentious transmission (i.e. reserved access or stealing). The MAC receives a TM-SDU from the LLC, transmits the TM-SDU (in one or more MAC blocks) and then reports to the LLC when the message has been sent. Acknowledgements and retransmissions are under the control of the LLC.

However, for contentious access (i.e. random access), the MS-MAC is responsible for sending retries until it receives a MAC response from the BS indicating successful random access. The report to the LLC shall then indicate that the BS has acknowledged the random access message.

TMA-SAP signalling messages may generally be sent using the MAC-RESOURCE or MAC-D-BLCK PDU for the downlink, or the MAC-ACCESS PDU (in a subslot) or MAC-DATA or MAC-U-BLCK PDU (in a full slot) for the uplink. A general scenario for an exchange of two LLC messages is shown in figure 23.1. (Other PDUs, MAC-FRAG and MAC-END(-HU), are used for continuations and end of a fragmented TM-SDU.)

The uplink MAC-ACCESS, MAC-DATA and MAC-U-BLCK PDUs include the layer 2 address and usually carry a TM-SDU; they can also be used to request reserved slots for signalling messages. On the downlink, the MAC-RESOURCE PDU usually includes layer 2 addressing and may contain a TM-SDU; the MAC-D-BLCK PDU includes a layer 2 address and may contain a TM-SDU. The MAC-RESOURCE PDU may also include elements for granting reserved slots and/or for channel allocation and/or for power control, and the MAC-D-BLCK PDU may include an element for granting reserved slots. The MAC PDUs are defined in clause 21.

**Figure 23.1: Scenario for exchange of two LLC messages**

### 23.1.2.1.1 Reports

When the MS-MAC receives a TMA-UNITDATA request primitive from the LLC, the primitive includes a local identifier for the service request, referred to as the "handle to the request". The handle should be retained locally and used for routing subsequent reports (TMA-REPORT indication primitive). It refers to all actions required in the MAC to accomplish the request.

The MS-MAC shall issue reports to the LLC at the following times:

- i) first transmission of complete TM-SDU by random access;
- ii) when the BS acknowledges reception of a complete TM-SDU sent by random access;
- iii) complete TM-SDU (or final fragment of a fragmented TM-SDU) has been sent by reserved access or by stealing;
- iv) random access failure;
- v) failure of fragmentation process (TM-SDU not completely sent).

Also, in the case of a TMA-CANCEL request primitive, the MS-MAC shall report whether or not the TM-SDU has been completely sent.

After sending reports ii), iii), iv), v), or after cancellation, the MS-MAC shall regard the requested procedure as complete. The MS-MAC shall discard the TM-SDU and the handle becomes invalid.

### 23.1.2.1.2 Buffering mechanism

When the MS-MAC receives a downlink PDU addressed to that MS, it shall immediately deliver any TM-SDU to the LLC using the TMA-UNITDATA indication primitive (except in the case of a fragmented message, when the MS-MAC shall reconstruct the entire TM-SDU before delivering it to the LLC).

For an MS sending PDUs, there may be many messages to be sent. For the purposes of the protocol description, it is assumed that the layer 2 queue of messages is held in the LLC and that the MAC has a single-message sending buffer only.

According to this protocol description, there shall be two related signals between MS-MAC and MS-LLC.

- i) DATA-IN-BUFFER signal from LLC to MAC.

This shall indicate:

- the total amount of outstanding signalling data that the LLC has ready to send for a particular address on the channel corresponding to the specified endpoint identifier, and not yet given to the MAC;

- if the channel corresponding to the specified endpoint identifier is a  $\pi/4$ -DQPSK channel and the MS supports data priority: the subdivision of the outstanding data into data priorities;
- if the channel corresponding to the specified endpoint identifier is a D8PSK or QAM channel: the subdivision of the outstanding data into data categories;
- if the channel corresponding to the specified endpoint identifier is a D8PSK or QAM channel and the MS supports data priority: the subdivision of the outstanding data into data categories and data priorities.

It shall also indicate:

- the maximum value of the stealing permission parameter for the messages in the LLC queue for that address and channel;
- the maximum value of the PDU priority parameter for unscheduled messages in the LLC queue for that address and channel;
- if the MS supports data priority:
  - the maximum value of the data priority parameter for the messages in the LLC queue for that address and channel; and
  - the type of the next message currently expected to be sent for that address and channel i.e. whether the next message will contain packet data or not;
- whether all, some or none of the messages in the LLC queue for that address and channel are fully scheduled data, and the lowest value of the maximum schedule interval for any fully scheduled data;
- the maximum value of the PDU priority parameter for fully scheduled messages in the LLC queue for that address and channel.

These parameters enable the MAC to decide on the appropriate means to transfer the information before receiving the actual service request.

ii) MAC-READY signal from MAC to LLC.

This signal shall be issued to the LLC when the MS-MAC is ready to send a MAC block.

If the MS is on a  $\pi/4$ -DQPSK channel, it shall indicate:

- the maximum size of TM-SDU that can be carried within the MAC PDU that the MS-MAC intends to send, i.e. the maximum size without requiring fragmentation.

If the MS is on a D8PSK channel, it shall indicate:

- the data categories for which a TM-SDU may be sent in the current MAC block;
- the maximum size of TM-SDU that can be carried in the current MAC block for each data category for which a TM-SDU may be sent (i.e. the maximum size without requiring fragmentation).

If the MS is on a QAM channel, it shall indicate:

- the current normal data segment size for advanced link data segments;
- the data categories for which a normal advanced link data segment may be sent in the current MAC block;
- the data categories for which a TM-SDU may be sent in the current MAC block;
- the maximum size of TM-SDU that can be carried in the current MAC block for some or all of the data categories for which a TM-SDU may be sent (i.e. the maximum size without requiring fragmentation).

It shall also indicate the absolute maximum size of TM-SDU that can be handled in the MAC at this time. This is normally the maximum size of fragmented TM-SDU (up to N.202 bits), but shall be reduced in the case of stealing to either the size of the MAC block or to the capacity of two half slots if two-half-slot stealing is appropriate at this time.

On receipt of the MAC-READY signal, the LLC will usually issue a TMA-UNITDATA request primitive to the MAC (see also clause 22).

NOTE: The ISSI and its associated ASSI are equivalent for the purposes of the buffering mechanism, so the MS may use the same signal for the ISSI and ASSI.

### 23.1.2.1.3 Usage of signals

This clause describes the usage of the MAC-READY and DATA-IN-BUFFER signals. The actual MAC procedures for fragmentation, association, random access, reserved access and stealing are described later in clause 23.

The procedures a), b) and c) below relate to the protocol model of the interface with the LLC and do not imply any specific implementation.

#### a) Random access

If the DATA-IN-BUFFER signal from the LLC indicates that there is only unscheduled data to send, and if the MS-MAC has neither been granted any reserved slots nor asked for reserved slots for that address on that channel, then the MS-MAC should prepare to initiate the random access procedure. The MS-MAC shall issue the MAC-READY signal to the LLC. On a  $\pi/4$ -DQPSK or D8PSK channel, the MAC-READY signal indicates the available size of TM-SDU within the MAC-ACCESS PDU. On a QAM channel, the MAC-READY signal indicates that there are no data categories for which a normal advanced link data segment may be sent in this MAC block; it may indicate the available size of TM-SDU within the MAC-ACCESS PDU:

- i) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that fits within the MAC block then the MAC-ACCESS PDU shall carry that TM-SDU. If there is still space within the MAC block for another PDU by association, the MS-MAC may repeat the MAC-READY/TMA-UNITDATA exchange process as required until there is not space for another MAC header.
- ii) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that does not fit within the MAC-ACCESS PDU then the MAC-ACCESS PDU shall carry a first fragment of the TM-SDU, using the fragmentation procedure and including a request for reserved capacity within the MAC-ACCESS PDU.
- iii) If the LLC does not issue a TMA-UNITDATA request primitive then the MAC-ACCESS PDU shall contain a request for reserved capacity but shall not carry a TM-SDU. This case may arise if the LLC has only advanced link messages to send at this time.

NOTE 1: The maximum available size of TM-SDU in the MAC-ACCESS PDU is variable, depending on whether the MS requests reserved capacity for further signalling.

NOTE 2: On a  $\pi/4$ -DQPSK or D8PSK channel, the random access message is always sent using  $\pi/4$ -DQPSK modulation (on SCH/HU). On a QAM channel, the random access message is always sent using 4-QAM modulation with coding rate = 1/2 and within a 25 kHz bandwidth (on SCH-Q/RA).

#### b1) Reserved access on a $\pi/4$ -DQPSK channel

When the MS-MAC has a reserved slot (or subslot) individually granted to it by the BS then, if it is already in the process of sending a fragmented TM-SDU, it shall send the next fragment. (In the case of a final fragment, if there is still space within the MAC block for another PDU by association, the MS-MAC may issue the MAC-READY signal as described below.) Or, if there is no data in the LLC buffer for that address and channel, the MS-MAC may send the Null PDU.

Otherwise, just before the transmission is due, the MS-MAC shall issue the MAC-READY signal to the LLC, announcing the maximum available size of TM-SDU in this MAC block (i.e. for a full slot, the maximum size of TM-SDU in a MAC-U-BLCK PDU (if supported and the MS has an event label) or otherwise in a MAC-DATA PDU; for a subslot, the maximum size of TM-SDU in a MAC-ACCESS PDU):

- i) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that fits within the MAC block then:
  - for a full slot, a MAC-DATA or MAC-U-BLCK PDU shall carry that TM-SDU; use of MAC-U-BLCK is appropriate if the MS has an event label and the TM-SDU occupies all, or most of, the MAC block;
  - for a subslot, a MAC-ACCESS PDU shall carry that TM-SDU.

In the case of a MAC-DATA or MAC-ACCESS PDU, if there is still space within the MAC block for another PDU by association, the MS-MAC may repeat the MAC-READY/TMA-UNITDATA exchange process as required until there is not space for another MAC header.

- ii) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that does not fit within the MAC block then the MAC-DATA PDU (for a full slot) or MAC-ACCESS PDU (for a subslot) shall carry a first fragment of the TM-SDU, using the fragmentation procedure and including a request for reserved capacity within the MAC-DATA or MAC-ACCESS PDU.
- iii) If the LLC does not issue a TMA-UNITDATA request primitive but the DATA-IN-BUFFER signal indicates that there is data to send then the MAC-DATA or MAC-ACCESS PDU shall contain a request for reserved capacity but shall not carry a TM-SDU. This case should not occur for the first PDU in a reserved full slot.

NOTE 3: The timing of the MAC-READY signal should be as late as possible, to allow the maximum time if the layer 3 in the MS is preparing a response to a BS message.

#### b2) Reserved access on a D8PSK channel

When on a D8PSK channel, the MS-MAC maintains an assessment of the appropriate modulation (i.e.  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK) for reserved access transmission for each of the data categories; see clause 23.4.9.

When the MS-MAC has a reserved slot (or subslot) individually granted to it by the BS then, if it is already in the process of sending a fragmented TM-SDU, it shall send the next fragment. (In the case of a final fragment, if there is still space within the MAC block for another PDU by association, the MS-MAC may issue the MAC-READY signal as described below.) Or, if there is no data in the LLC buffer for that address and channel, the MS-MAC may send the Null PDU.

Otherwise, just before the transmission is due, the MS-MAC shall issue the MAC-READY signal to the LLC, announcing the maximum available size of TM-SDU in this MAC block for each data category.

NOTE 4: The maximum available size of TM-SDU will take one of two values, depending on whether the MS-MAC would send data for each data category using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation. So, for example, if the MS-MAC currently intends to send the first transmission(s) of any advanced link segments for background class data using  $\pi/8$ -D8PSK modulation, but would send the first transmission(s) of advanced link segments for telemetry class data using  $\pi/4$ -DQPSK modulation, the information in the MAC-READY signal enables the LLC to cut new advanced link segments of the appropriate size.

Any TMA-UNITDATA request primitive issued by the LLC indicates the data category for the TM-SDU:

- i) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that fits within the MAC block using the modulation appropriate for the indicated data category then:
  - for a full slot, a MAC-DATA or MAC-U-BLCK PDU shall carry that TM-SDU; use of MAC-U-BLCK is appropriate if the MS has an event label and the TM-SDU occupies all, or most of, the MAC block;
  - for a subslot, a MAC-ACCESS PDU shall carry that TM-SDU.

In the case of a MAC-DATA or MAC-ACCESS PDU, if there is still space within the MAC block for another PDU by association, the MS-MAC may repeat the MAC-READY/TMA-UNITDATA exchange process as required until there is not space for another MAC header.

In the second (and subsequent) MAC-READY signal for a MAC block, the MS-MAC shall indicate the data categories for which a TM-SDU may be sent and the maximum available size of TM-SDU in this MAC block for each data category.

EXAMPLE 1: If the first TM-SDU can be sent using  $\pi/8$ -D8PSK modulation and fits within a  $\pi/8$ -D8PSK MAC block (with space remaining) but would not fit within a  $\pi/4$ -DQPSK MAC block then, in the second MAC-READY signal, the MS-MAC should not invite data for data categories that need to use  $\pi/4$ -DQPSK modulation. If the first TM-SDU can be sent using  $\pi/8$ -D8PSK modulation but would fit within a  $\pi/4$ -DQPSK MAC block (with space remaining) then, in the second MAC-READY signal, the MS-MAC may choose to invite data for all data categories.

If the second (or subsequent) TMA-UNITDATA request primitive indicates a data category for which a different modulation is appropriate, it is expected that the MS-MAC would use the lower of the modulation levels.

- ii) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that does not fit within the MAC block using the modulation appropriate for the indicated data category then the MAC-DATA PDU (for a full slot) or MAC-ACCESS PDU (for a subslot) shall carry a first fragment of the TM-SDU, using the fragmentation procedure and including a request for reserved capacity within the MAC-DATA or MAC-ACCESS PDU.
- iii) If the LLC does not issue a TMA-UNITDATA request primitive but the DATA-IN-BUFFER signal indicates that there is data to send then the MAC-DATA or MAC-ACCESS PDU shall contain a request for reserved capacity but shall not carry a TM-SDU. This case should not occur for the first PDU in a reserved full slot.

After performing the above process, the MS-MAC should use the appropriate modulation according to the data category (or categories) of the PDU(s) but with the following exception: if the appropriate modulation for the PDU(s) to be sent in a MAC block is  $\pi/8$ -D8PSK according to the data category (or categories), but the PDU(s) would actually fit within a  $\pi/4$ -DQPSK MAC block, the MS-MAC shall use  $\pi/4$ -DQPSK modulation.

### b3) Reserved access on a QAM channel

When on a QAM channel, the MS-MAC maintains an assessment of the appropriate modulation level and coding rate for reserved access transmission for each of the data categories; see clause 23.4.9.

When the MS-MAC has a reserved slot (or subslot) individually granted to it by the BS then, if it is already in the process of sending a fragmented TM-SDU, it shall send the next fragment. (In the case of a final fragment, if there is still space within the MAC block for another PDU by association, the MS-MAC may issue the MAC-READY signal as described below.) Or, if there is no data in the LLC buffer for that address and channel, the MS-MAC may send the Null PDU.

Otherwise, just before the transmission is due, the MS-MAC shall issue the MAC-READY signal to the LLC, announcing the current normal data segment size for advanced link data segments, the data categories for which a normal advanced link data segment may be sent in the current MAC block and the maximum available size of TM-SDU in this MAC block for appropriate data categories.

NOTE 5: On a 25 kHz or 50 kHz QAM channel, the normal advanced link segment size is determined by the available space in a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth; on a 100 kHz or 150 kHz QAM channel, the normal advanced link segment size is determined by the available space in half of a 4-QAM rate = 1/2 full-slot MAC block at the current bandwidth.

NOTE 6: In the first MAC-READY signal in a reserved slot, the MS-MAC should allow normal advanced link data segments for all data categories. For a reserved subslot, the MS-MAC should indicate any data categories for which a normal advanced link segment would fit into the subslot using the modulation level and coding rate appropriate for that data category.

Any TMA-UNITDATA request primitive issued by the LLC indicates the data category for the TM-SDU:

- i) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that fits within the MAC block using the modulation level and coding rate appropriate for the indicated data category then:
  - for a full slot, a MAC-DATA or MAC-U-BLCK PDU shall carry that TM-SDU; use of MAC-U-BLCK is appropriate if the MS has an event label and the TM-SDU would occupy all, or most of, the MAC-U-BLCK PDU;
  - for a subslot, a MAC-ACCESS PDU shall carry that TM-SDU.

NOTE 7: The implicit length of the MAC-U-BLCK PDU on a QAM channel is set to correspond to the size of a normal advanced link data segment.

If there is still space within the MAC block for another PDU by association, the MS-MAC may repeat the MAC-READY/TMA-UNITDATA exchange process as required until there is not space for another MAC header.

In the second (and subsequent) MAC-READY signal for a MAC block, the MS-MAC shall indicate the data categories for which a normal advanced link data segment may be sent in the current MAC block, the data categories for which a TM-SDU may be sent and the maximum available size of TM-SDU in this MAC block for appropriate data categories.

**EXAMPLE 2:** On a 25 kHz or 50 kHz channel, if the first TM-SDU is a normal data segment that can be sent using 16-QAM rate = 1/2, the MS-MAC should not invite any data (either a normal data segment or any other data) for data categories that need to use 4-QAM rate = 1/2. Similarly, on a 25 kHz or 50 kHz channel, if the first TM-SDU is a normal data segment that can be sent using 64-QAM rate = 1/2, the MS-MAC should not invite any data (either a normal data segment or any other data) for data categories that need to use 4-QAM rate = 1/2; however the MS-MAC may choose to invite data (either a normal data segment or any other data) for data categories that need to use 16-QAM rate = 1/2.

If the second (or subsequent) TMA-UNITDATA request primitive indicates a data category for which a different modulation level and/or coding rate is appropriate, it is expected that the MS-MAC would normally use the lower (or lowest) of the modulation levels and/or coding rates.

- ii) If the LLC issues a TMA-UNITDATA request primitive containing a TM-SDU that does not fit within the MAC block using the modulation level and coding rate appropriate for the indicated data category then the MAC-DATA PDU (for a full slot) or MAC-ACCESS PDU (for a subslot) shall carry a first fragment of the TM-SDU, using the fragmentation procedure and including a request for reserved capacity within the MAC-DATA or MAC-ACCESS PDU.
- iii) If the LLC does not issue a TMA-UNITDATA request primitive but the DATA-IN-BUFFER signal indicates that there is data to send then the MAC-DATA or MAC-ACCESS PDU shall contain a request for reserved capacity but shall not carry a TM-SDU. This case should not occur for the first PDU in a reserved full slot.

After performing the above process, the MS-MAC should use the appropriate modulation level and coding rate according to the data category (or categories) of the PDU(s) but with the following exception: if the PDU(s) would actually fit within a MAC block using a lower modulation and/or coding rate, the MS-MAC shall use that lower modulation level and/or coding rate.

**NOTE 8:** The above procedure relates to the protocol model of the interface with the LLC and does not imply any specific implementation. It may be noted that:

- on a 25 kHz or 50 kHz QAM channel, two, four, three, four or six advanced link data segments can be sent by association within a full slot when using 16-QAM rate = 1/2, 16-QAM rate = 1, 64-QAM rate = 1/2, 64-QAM rate = 2/3 or 64-QAM rate = 1 respectively;
- on a 100 kHz or 150 kHz QAM channel, two, four, eight, six, eight or twelve advanced link data segments can be sent by association within a full slot when using 4-QAM rate = 1/2, 16-QAM rate = 1/2, 16-QAM rate = 1, 64-QAM rate = 1/2, 64-QAM rate = 2/3 or 64-QAM rate = 1 respectively.

According to the protocol model, the data segments are provided by the LLC by using multiple MAC-READY and TMA-UNITDATA request exchanges. However implementers may choose to use a more optimized process.

### c) Stealing

When the MS is transmitting in a circuit mode call on a  $\pi/4$ -DQPSK channel, and if there is data in the LLC buffer for that channel for which the stealing permission parameter indicates that stealing may be used, then the MS-MAC shall issue the MAC-READY signal to the LLC indicating:

- the size of TM-SDU in this MAC block; and
- the maximum valid size of TM-SDU, given any current stealing limitations.

The fragmentation and association mechanisms may apply as described above for a  $\pi/4$ -DQPSK channel. If the LLC does not issue a TMA-UNITDATA request primitive, for example because the message is too long, then the MS-MAC shall not perform the stealing but may use the TMA-SAP procedures (i.e. random access and/or reserved access) to send the messages in the LLC buffer.

NOTE 9: The MAC-U-BLCK PDU cannot be used on the stealing channel.

#### 23.1.2.1.4 Priority, subscriber class and scheduled data information

The TMA-UNITDATA request primitive includes the layer 2 PDU priority of the message, the stealing permission parameter and the subscriber class parameter. The DATA-IN-BUFFER signal indicates the maximum PDU priority and stealing permission parameter in the LLC queue. The DATA-IN-BUFFER signal may also indicate the maximum data priority parameter in the LLC queue and the amount of data in the LLC queue for each data priority (and for each data category on a D8PSK or QAM channel), and may indicate whether the next message to be sent is expected to contain packet data; the TMC-CONFIGURE request primitive may indicate the MS default data priority that the higher layers have negotiated with the SwMI. Also the DATA-IN-BUFFER signal provides information about whether all, some or none of the messages in the LLC queue are fully scheduled data and the lowest value of the maximum schedule interval for any fully scheduled data. The MS-MAC shall use these parameters as follows:

- i) The MS-MAC may need to use the PDU priority and subscriber class parameter from the TMA-UNITDATA request primitive in the random access procedure, if the BS has announced PDU priority or subscriber class restrictions on random access at this time.
- ii) The PDU priority information from the DATA-IN-BUFFER signal may also be used to cut short the reserved access waiting time-out if there is an emergency message in the LLC buffer, so that the MS may initiate the random access procedure.
- iii) The stealing permission parameter may be used to trigger the stealing mechanism.
- iv) The information about the maximum data priority and/or the amount of data in the LLC queue for each data priority, together with the MS default data priority, may be used by the MS-MAC to decide when to send its current short-term data priority requirements to the BS and the appropriate information to include.
- v) The information about whether the LLC currently expects that the next PDU to be sent will contain packet data may be used by the MS-MAC to decide whether it may initiate the random access procedure.
- vi) The information about scheduled data enables the MS-MAC to decide whether and when to use random access to request to send the data in the LLC buffer.

There are eight possible levels of the layer 2 PDU priority, from the lowest priority 0, increasing to the highest priority 7 corresponding to an emergency message.

There are eight defined levels of the data priority and MS default data priority, from the lowest priority 0, increasing to the highest priority 7. Also the data priority parameter may contain the value "undefined", and the MS default data priority parameter may contain the value "not applicable".

There are 16 possible subscriber classes, allowing a population subdivision, e.g. for random access control. The operator defines the values and meaning of each class, and the MS may belong to one or more of those classes. The subscriber class parameter, as supplied in primitives from the higher layers, is a bit-mapped field which indicates, for each class, whether the MS belongs to that class.

The stealing permission parameter defines whether the MAC may use stealing to send this message, if the MS is currently transmitting traffic on a  $\pi/4$ -DQPSK channel. It may have the following meanings:

- stealing not required;
- steal when convenient;
- steal within time T.214; or
- steal immediately.

NOTE: If the MS is not transmitting traffic, the MAC ignores the stealing permission parameter.

### 23.1.2.2 Services at the TMB-SAP

The TMB-SAP shall be used for the transfer of un-addressed system broadcast messages. The primitives shall be TMB-SYNC, TMB-SYSINFO, TMB-SYSINFO-Q, TMB-SYNC-DA and TMB-SYSINFO-DA. The request primitive shall be used in the BS. The indication primitive shall be used in the MS to deliver the TM-SDU to the higher layers.

The corresponding PDUs shall be the SYNC PDU (contained in the BSCH), SYSINFO PDU (contained in the BNCH), SYSINFO-Q PDU (contained in the BNCH-Q), SYNC-DA PDU (contained in the BSCH-Q) and SYSINFO-DA PDU (generally contained in the BNCH-Q). These PDUs contain many MAC elements, and also include a TM-SDU used by the MLE.

**NOTE:** The SYNC and SYSINFO PDUs are sent only on  $\pi/4$ -DQPSK and D8PSK channels. The information from SYNC and SYSINFO PDUs is used by Conventional Access (CA) MSs - and also by Direct Access (DA) MSs when they are on a  $\pi/4$ -DQPSK or D8PSK assigned channel.

The SYSINFO-Q PDU is sent only on QAM channels. The information from SYSINFO-Q PDUs is used only by CA MSs, when they are on a QAM assigned channel.

The SYNC-DA is sent only on QAM channels. The information from SYNC-DA PDUs is used only by DA MSs. (The BS should not send the SYNC-DA PDU on an assigned channel if that assigned channel is being used by DA MSs from more than one DA cell.)

The information from SYSINFO-DA PDUs is used only by DA MSs. The SYSINFO-DA PDU is sent mostly on QAM channels, but may also be sent on  $\pi/4$ -DQPSK and D8PSK channels.

**EXAMPLE:** The BS may wish to send the SYSINFO-DA PDU on a  $\pi/4$ -DQPSK or D8PSK assigned channel if it moves the DA main carrier while there are DA MSs on the  $\pi/4$ -DQPSK or D8PSK assigned channel. (However, the BS should not send the SYSINFO-DA PDU on an assigned channel if that assigned channel is being used by DA MSs from more than one DA cell. Thus this example is not applicable if the  $\pi/4$ -DQPSK or D8PSK assigned channel is being used by DA MSs from more than one DA cell.)

### 23.1.2.3 Services at the TMC-SAP

The TMC-SAP shall be used for the transfer of local layer management information. It provides no data transfer services over the air interface. It shall be used, for example, for the higher layers to instruct the MAC to reconfigure its parameters, for the MLE to direct monitoring and scanning procedures in the MAC and for the MAC to issue reports on progress.

### 23.1.2.4 Services at the TMD-SAP

The TMD-SAP shall provide the interface between the MAC and the circuit mode U-plane application, e.g. the speech CODEC. It shall be used for the transfer of speech frames or circuit mode data. It shall also be used if the U-plane application steals from the traffic capacity to send encryption synchronization information and/or user-to-user signalling messages.

**NOTE:** Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels.

The TMD-UNITDATA request primitive from the U-plane application to the MAC shall be used when the U-plane application wishes to send data to the peer entity.

The TMD-UNITDATA indication primitive from the MAC to the U-plane application shall be used to deliver data from the peer entity.

There is also a TMD-REPORT indication primitive, which shall be used by the MAC to issue reports to the U-plane application e.g. when the MAC has stolen capacity from the traffic channel.

### 23.1.2.5 Use of channels and endpoint identifiers

#### 23.1.2.5.1 Channel usage

A Conventional Access (CA) MS receives a  $\pi/4$ -DQPSK common control channel, i.e. the MCCH or a  $\pi/4$ -DQPSK common SCCH, unless directed by the BS to an assigned channel - assigned for a circuit mode call or for secondary control (see clause 23.3). A  $\pi/4$ -DQPSK common control channel comprises one timeslot per TDMA frame, whereas an assigned channel comprises one or more timeslots per TDMA frame. It is optional for a CA MS to be capable of using a multi-slot channel.

NOTE 1: An assigned channel (either a single-slot or a multi-slot channel) may be a  $\pi/4$ -DQPSK, D8PSK or QAM channel. It is optional for a CA MS to be capable of using a D8PSK or QAM channel.

A Direct Access (DA) MS receives a QAM common control channel, i.e. the MCCH-Q or a QAM common SCCH, unless directed by the BS to an assigned channel - assigned for secondary control or for a circuit mode call (see clause 23.3). The MCCH-Q comprises one or more timeslots per TDMA frame, whereas a QAM common SCCH comprises only one timeslot per TDMA frame. An assigned channel comprises one or more timeslots per TDMA frame. It is mandatory for a DA MS to be capable of using a multi-slot QAM channel.

NOTE 2: An assigned channel (either a single-slot or a multi-slot channel) may be a QAM,  $\pi/4$ -DQPSK or D8PSK channel. It is optional for a DA MS to be capable of using a  $\pi/4$ -DQPSK or D8PSK channel.

Support of multi-slot phase modulation channels and multi-slot QAM channels is indicated separately (see clause 16):

- If the MS supports multi-slot phase modulation channels then:
  - if the MS supports  $\pi/4$ -DQPSK operation, it shall support at least one-slot and two-slot  $\pi/4$ -DQPSK channels; and it is recommended that the MS supports three-slot and four-slot  $\pi/4$ -DQPSK channels;
  - if the MS supports D8PSK operation, it shall support at least one-slot and two-slot D8PSK channels; and it is recommended that the MS supports three-slot and four-slot D8PSK channels.
- If the MS supports multi-slot QAM channels, it shall support one-slot, two-slot, three-slot and four-slot QAM channels.

#### 23.1.2.5.2 Endpoint identifiers

The MS may be capable of processing only one channel at a time, either a common control channel or an assigned channel.

Other MSs may be capable of processing more than one channel simultaneously, allowing concurrent MAC services to be provided. The "endpoint identifier" is a local identifier used to distinguish between multiple concurrent service instances.

At the LLC-MAC boundary, the endpoint identifier shall refer to the use of a particular MAC channel, i.e. common control channel or assigned channel. It identifies the MAC channel to which a particular TMA-UNITDATA or TMD-UNITDATA or TLE-UNITDATA primitive (or DATA-IN-BUFFER or MAC-READY signal) applies. There shall be a unique correspondence between the endpoint identifier and the physical channel allocation used in the MAC (i.e. the timeslot for a single-slot channel or timeslots for a multi-slot channel).

NOTE 1: This correspondence is known only within the MAC. The endpoint identifier is used by the higher layers as a label to refer to a particular MAC resource, so the MAC may change (i.e. replace) the actual physical allocation without changing the endpoint identifier.

NOTE 2: A MAC channel may carry both the advanced link and basic link signalling. For the purposes of the procedures for transmission and reception of signalling messages, the MAC does not generally make any distinction between advanced link and basic link messages. However, on a D8PSK or QAM channel, advanced link and basic link messages may be treated differently for link adaptation purposes. Also, on a QAM channel, the MAC is aware of the normal advanced link data segment size.

## 23.1.3 MS capabilities

### 23.1.3.0 General

The following clauses describe the capabilities of a frequency full duplex and half duplex MS. All MSs shall provide frequency half duplex capability while an MS may also provide fast switching capability or support frequency full duplex operation.

#### 23.1.3.1 Frequency half duplex operation

##### 23.1.3.1.1 Frequency half duplex capability

A frequency half duplex MS has the ability either to transmit on an uplink frequency or receive on a downlink frequency at any time. It is not able to transmit and receive at the same time. This type of MS also requires time to switch from its transmit to receive frequency. This shall be no more than a timeslot duration.

Figure 23.2 shows the uplink and downlink slots of a single TDMA frame, with "x" marking an example of slots which can be used by a frequency half duplex MS. Only one downlink and the corresponding (same-numbered) uplink slot can be used in a single TDMA frame. If both the uplink and downlink slot in figure 23.2 are used by a single MS, time division duplex operation can be realized allowing a frequency half duplex MS to support single-slot duplex call services.

**Figure 23.2: Frequency half duplex operation**

In the example shown, the MS can receive the downlink slot and also transmit in the corresponding uplink slot. It is also possible for a frequency half duplex MS to operate with a multi-slot channel. However, in this case, the BS should not send signalling messages to that MS when the MS is transmitting traffic or transmitting in reserved slots (or switching from receive to transmit or from transmit to receive).

##### 23.1.3.1.2 Fast switching capability

A frequency half duplex MS may be capable of switching from transmit to receive, and from receive to transmit, between contiguous slots (e.g. capable of transmitting in uplink slot 2 and then receiving in the immediately following downlink slot 1). This type of MS is defined as a fast switching MS. A fast switching MS may fully support e.g.:

- two concurrent single-slot channels; and/or
- a two-slot duplex call service;

provided that the BS allocates the two slots with adjacent numbers (i.e. slots 1 and 2, or 2 and 3, or 3 and 4, or 4 and 1). Figure 23.3 shows the uplink and downlink slots of a single TDMA frame, with "x" marking an example of slots which can be used by a fast switching MS.

**Figure 23.3: Frequency half duplex operation with fast switching capability**

**NOTE:** Fast switching capability on a  $\pi/4$ -DQPSK or D8PSK channel is indicated in the "class of MS" element; see clause 16. Fast switching capability on a QAM channel is indicated independently in the "extended capabilities" element; see clause 16.

### 23.1.3.2 Frequency full duplex operation

A frequency full duplex MS has the ability to transmit on an uplink frequency and receive on a downlink frequency at the same time. Therefore, this type of MS can use all timeslots in a TDMA frame. Figure 23.4 shows the uplink and downlink slots of a single TDMA frame, with "x" marking those slots which can be used by a frequency full duplex MS. Any combination of these slots may be used for a single call or for multiple calls.

**Figure 23.4: Frequency full duplex operation**

NOTE: Frequency full duplex capability is indicated in the "class of MS" element; see clause 16.

### 23.1.3.3 Basic capabilities of the physical layer

The following performance is expected from the physical layer for a TETRA MS.

An MS shall be capable of changing from one frequency to another frequency in less than 1 timeslot duration.

An MS shall be capable of changing from reception to transmission or from transmission to reception in less than 1 timeslot duration.

An MS shall be capable of a combined frequency change and changing from reception to transmission or from transmission to reception in less than 1 timeslot duration.

A fast switching MS shall be capable of changing from reception to transmission or from transmission to reception between contiguous timeslots. Fast switching capability is optional in the MS.

NOTE 1: When changing from one frequency to another frequency, or when combining a frequency change with a change from reception to transmission or from transmission to reception, a fast switching MS operates like a normal frequency half duplex MS i.e. switching in less than 1 timeslot duration.

A frequency full duplex MS shall be capable of changing reception or transmission frequency (or both) in less than 1 timeslot duration. Frequency full duplex operation is optional in the MS.

An MS that is capable of operating on a  $\pi/4$ -DQPSK or D8PSK channel should be capable of receiving and decoding the AACH in contiguous timeslots. A CA MS that is capable of operating on a QAM channel should be capable of receiving and decoding the AACH-Q in contiguous QAM timeslots. A DA MS shall be capable of receiving and decoding the AACH-Q in contiguous QAM timeslots.

A CA MS may be capable of receiving or transmitting full slots of information in contiguous timeslots. A DA MS shall be capable of receiving or transmitting full slots of information in contiguous timeslots on a QAM channel i.e. a DA MS shall be capable of using a multi-slot QAM channel. A DA MS may be capable of receiving or transmitting full slots of information in contiguous timeslots on a  $\pi/4$ -DQPSK or D8PSK channel.

NOTE 2: When changing from reception, the MS may need to receive the downlink beyond the start of the next slot in order to decode the current slot. Similarly, when changing to reception, the MS may need to start receiving the downlink before the start of the slot in order to decode that slot. This reduces the time available for the change to less than 14,167 ms. See clauses 7, 9.4.3.4 and 9.4.7.4 for the definition of the start of the slot.

### 23.1.3.4 Modulation and bandwidth capabilities

#### 23.1.3.4.1 General

There are three modulations modes for channels:

- $\pi/4$ -DQPSK (using  $\pi/4$ -DQPSK bursts);
- D8PSK (using both  $\pi/4$ -DQPSK and  $\pi/8$ -D8PSK bursts); and
- QAM (using QAM bursts).

In the case of a  $\pi/4$ -DQPSK or D8PSK channel, the bandwidth of the channel is 25 kHz. In the case of a QAM channel, the bandwidth of the channel is 25 kHz, 50 kHz, 100 kHz or 150 kHz.

#### 23.1.3.4.2 MS modulation and bandwidth capabilities

An MS shall support Conventional Access (CA) operation or Direct Access (DA) operation or both (see note 3).

An MS that supports CA operation shall support  $\pi/4$ -DQPSK channels. It may support D8PSK channels (see note 2), and it may support QAM channels (see note 3).

An MS that supports DA operation shall support QAM channels. It may support  $\pi/4$ -DQPSK channels (see notes 2 and 3), and it may support D8PSK channels (see note 2).

If an MS supports QAM channels:

- it is optional which QAM channel bandwidths the MS supports (see note 3);
- the MS shall support transmission within random access uplink RF channel subslots (which have 25 kHz bandwidth irrespective of the QAM channel bandwidth);

NOTE 1: This requirement applies even if the MS does not support 25 kHz QAM channels.

- the MS shall support 4-QAM and 16-QAM, for both transmission and reception;
- the MS may support 64-QAM (see note 3);
- if the MS supports 64-QAM, it shall support either:
  - 64-QAM transmission and reception; or
  - 64-QAM reception only;
- the MS shall support reception of the following combinations of modulation level and coding rate:
  - 4-QAM, coding rate = 1/2;
  - 16-QAM, coding rate = 1/2; and
  - 16-QAM, coding rate = 1;
- the MS shall support transmission of the following combinations of modulation level and coding rate:
  - 4-QAM, coding rate = 1/2; and
  - 16-QAM, coding rate = 1/2;
- the MS may support transmission of 16-QAM, coding rate = 1;

- additionally, if the MS supports 64-QAM, it shall support reception of the following combinations of modulation level and coding rate:
  - 64-QAM, coding rate = 1/2;
  - 64-QAM, coding rate = 2/3; and
  - 64-QAM, coding rate = 1;
- if the MS supports 64-QAM for transmission, it shall support transmission of the following combinations of modulation level and coding rate:
  - 64-QAM, coding rate = 1/2; and
  - 64-QAM, coding rate = 2/3;

the MS may support transmission of 64-QAM, coding rate = 1.

NOTE 2: These MS capabilities are indicated in the "class of MS" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

NOTE 3: These MS capabilities are indicated in the "extended capabilities" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

#### 23.1.3.4.3 BS modulation and bandwidth capabilities

A BS that is capable of CA operation shall support  $\pi/4$ -DQPSK channels. It may support D8PSK channels (see note 2), and it may support QAM channels (see note 2).

A BS that is capable of DA operation shall support QAM channels. It may support  $\pi/4$ -DQPSK channels (see notes 3 and 4), and it may support D8PSK channels (see note 3).

If the BS supports QAM channels:

- it is optional which QAM channel bandwidths the BS supports and provides (see notes 2 and 3);
- the BS shall support reception of random access uplink RF channel subslots (which have 25 kHz bandwidth irrespective of the QAM channel bandwidth);

NOTE 1: This requirement applies even if the BS does not support 25 kHz QAM channels.

- the BS shall support 4-QAM and 16-QAM, for both transmission and reception;
- the BS may support 64-QAM (see notes 5 and 6);
- if the BS supports 64-QAM, it shall support either:
  - 64-QAM transmission and reception; or
  - 64-QAM reception only;
- the BS shall support reception of the following combinations of modulation level and coding rate:
  - 4-QAM, coding rate = 1/2;
  - 16-QAM, coding rate = 1/2; and
  - 16-QAM, coding rate = 1;
- the BS shall support transmission of the following combinations of modulation level and coding rate:
  - 4-QAM, coding rate = 1/2; and
  - 16-QAM, coding rate = 1/2;
- the BS may support transmission of 16-QAM, coding rate = 1;

- additionally, if the BS supports 64-QAM, it shall support reception of the following combinations of modulation level and coding rate:
  - 64-QAM, coding rate = 1/2;
  - 64-QAM, coding rate = 2/3; and
  - 64-QAM, coding rate = 1;
- if the BS supports 64-QAM for transmission, it shall support transmission of the following combinations of modulation level and coding rate:
  - 64-QAM, coding rate = 1/2; and
  - 64-QAM, coding rate = 2/3;

the BS may support transmission of 64-QAM, coding rate = 1.

NOTE 2: For CA, support of these services is indicated in the "extended services broadcast" element in the SYSINFO and SYSINFO-Q PDUs; see clauses 21.4.4.1 and 21.4.4.1a.

NOTE 3: For DA, support of these services is indicated in the "extended DA services broadcast" element in the SYSINFO-DA PDU; see clause 21.4.4.1b. The SYNC-DA PDU also indicates the QAM channel bandwidths that the BS supports on this cell; see clause 21.4.4.2a.

NOTE 4: For DA, support of the TETRA voice service and circuit mode data service is indicated in the "BS service details DA" element in the D-MLE-SYNC-DA and D-MLE-SYSINFO-DA PDUs; see clause 18.

NOTE 5: The BS indicates the maximum modulation level that the MS is permitted to use on the uplink of a QAM assigned channel when it sends the channel allocation.

NOTE 6: For DA, the BS indicates in the SYSINFO-DA PDU the maximum modulation level that a DA MS is permitted to use on the uplink of a QAM common control channel.

### 23.1.4 Services provided by the LLC to the MAC

As described in clause 23.1, the MAC provides services to the LLC through the TMA-SAP, TMB-SAP and TMC-SAP (and to the U-plane application through the TMD-SAP).

There may be an additional SAP between the LLC and the MAC: the TLE-SAP; this is the layer 2 signalling SAP. The LLC provides a data transfer service to the MAC through this SAP, for layer 2 signalling. Layer 2 signalling PDUs carry various types of general signalling information relating to layer 2 functions; the layer 2 signalling PDUs are treated as LLC PDUs in the PDU structures.

The information transfer service provided by the LLC to the MAC is an unacknowledged service.

NOTE 1: However, if the LLC reports that the message transfer was successfully completed by random access, the MS-MAC can deduce that the message was received by the BS.

The MAC may request the LLC to repeat a layer 2 signalling message, to increase the probability of a correct reception. On reception, the LLC does not suppress received duplicates.

The LLC provides the layer 2 signalling service to the MAC using the following primitives:

- the TLE-UNITDATA request primitive from the MAC to the LLC shall be used when the MAC wishes to send a layer 2 signalling message;
- the TLE-UNITDATA indication primitive from the LLC to the MAC shall be used to deliver a layer 2 signalling message corresponding to a MAC function;
- the LLC shall report the progress of a request procedure locally to the MAC using the TLE-REPORT indication primitive;
- the MAC may abort a TLE-UNITDATA request using the TLE-CANCEL request primitive.

See clause 20 for a detailed description of the service primitives.

The TLE-SAP boundary is defined to clarify the protocol description and does not imply any specific implementation. The word "shall" is used to describe this SAP and the primitives for traceability reasons in the protocol model, but they are not testable.

When the LLC sends or receives a layer 2 signalling PDU, it uses the data transfer service offered by the MAC at the TMA-SAP (similar to the procedures when the LLC sends a PDU as a result of receiving a basic link TL-UNITDATA request primitive from the MLE).

NOTE 2: Therefore, when the MAC wishes to send a layer 2 signalling message, the following process applies according to the protocol model:

- the MAC issues a TLE-UNITDATA request primitive to the LLC containing the information to be sent in the layer 2 signalling PDU;
- the LLC indicates to the MAC that there is data to be sent, using the DATA-IN-BUFFER signal;
- on receipt of an appropriate MAC-READY signal from the MAC, the LLC forms the layer 2 signalling PDU and issues it to the MAC in a TMA-UNITDATA request primitive; this process may be repeated (in different MAC blocks) if the PDU is to be sent more than once;
- on receipt of TMA-REPORT indication primitive(s) from the MAC relating to the layer 2 signalling PDU, the LLC issues TLE-REPORT indication primitive(s) to the MAC in order to report the progress or result of the procedure;
- on receipt of a TLE-CANCEL request primitive from the MAC, the LLC issues a TMA-CANCEL request primitive (if the LLC has issued the message to the MAC); the LLC indicates the result of the cancellation to the MAC using the TLE-REPORT indication primitive.

In the case of reception of a layer 2 signalling message, the following process applies:

- the MAC issues a TMA-UNITDATA indication primitive to the LLC to deliver a received TM-SDU;
- if the received LLC PDU is a layer 2 signalling PDU corresponding to a MAC function, the LLC delivers the information in the PDU to the MAC using a TLE-UNITDATA indication primitive.

In the present document, the layer 2 signalling PDUs are used only for MAC functions - for data priority and link adaptation purposes:

- the MS may send the L2-DATA-PRIORITY PDU; see clause 23.4.7;
- the MS may send the L2-LINK-FEEDBACK-INFO PDU; see clause 23.4.9;
- the BS may send the L2-SCHEDULE-SYNC PDU; see clause 23.5.2.6;
- the BS may send the L2-LINK-FEEDBACK-CONTROL or L2-LINK-FEEDBACK-INFO PDU; see clause 23.4.9.

Also, the MS may send a combined L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU; however, for the purposes of the protocol model, the combining is performed by the LLC (see clause 22.3.1.7.3) so the MS-MAC does not issue the combined message.

NOTE 3: This does not imply any specific implementation.

## 23.2 Services provided by the lower MAC and channel modes

### 23.2.1 Services at the TMV-SAP

In the protocol model, the MAC layer is divided into two sub-layers, i.e. upper and lower MAC, as described in clause 19. The lower MAC shall provide the following services to the upper MAC protocol:

- transfer of MAC PDUs using suitable physical layer bursts in accordance with the chosen TDMA timeslot;
- report of PDU transfer related exceptions;

- signal strength measurement (i.e. RSSI);
- channel coding and scrambling as described in clause 8:
  - Cyclic Redundancy Check (CRC) calculation;
  - Forward Error Correction (FEC) and interleaving of MAC blocks;
  - scrambling and de-scrambling of MAC blocks;
- on a  $\pi/4$ -DQPSK or D8PSK channel: choice of training sequence and channel coding corresponding to the slot flag value and vice versa;
- on a D8PSK channel: choice of training sequence corresponding to the modulation and vice versa;
- control of the transmitted power, frequency, frequency band, duplex spacing and precise time synchronization as described in clauses 6 and 10.

The lower MAC provides these services to the upper MAC via the TMV-SAP using the TMV-UNITDATA and TMV-CONFIGURE primitives:

- the TMV-UNITDATA request primitive shall be used to request the lower MAC to transmit a MAC block;
- the TMV-UNITDATA indication primitive shall be used by the lower MAC to deliver a received MAC block;
- the TMV-CONFIGURE primitive shall be used to provide the lower MAC with information about the configuration of the channel or about the format of a received slot.

NOTE 1: More than one TMV-UNITDATA request primitive may be needed to supply the information to be transmitted in a single slot or subslot. Similarly, more than one TMV-UNITDATA indication primitive may be needed to deliver the information received in a single slot (or subslot for the BS).

Tables 23.1 and 23.2 show the correspondence between the TMV-UNITDATA service primitives at the TMV-SAP and the associated parameters in the TMV-UNITDATA service primitive respectively. Table 23.3 shows the parameters in the TMV-CONFIGURE service primitive.

**Table 23.1: Correspondence between the upper and lower MAC at the TMV-SAP**

| Upper MAC Service Primitive  | Lower MAC Service Primitive (TMV-SAP) |
|--|---------------------------------------|
| TMA-UNITDATA request or<br>TMB-SYNC request (BS only) or<br>TMB-SYNC-DA request (BS only) or<br>TMB-SYSINFO request (BS only) or<br>TMB-SYSINFO-Q request (BS only) or<br>TMB-SYSINFO-DA request (BS only) or<br>TMD-UNITDATA request                      | TMV-UNITDATA request                  |
| TMA-UNITDATA indication or<br>TMB-SYNC indication (MS only) or<br>TMB-SYNC-DA indication (MS only) or<br>TMB-SYSINFO indication (MS only) or<br>TMB-SYSINFO-Q indication (MS only) or<br>TMB-SYSINFO-DA indication (MS only) or<br>TMD-UNITDATA indication | TMV-UNITDATA indication               |

**Table 23.2: Parameters used in the TMV-UNITDATA primitive**

| Parameter  | Request | Indication |
|--|---------|------------|
| MAC block  | M       | M          |
| MAC block length (see note)                            | M       | M          |
| Logical channel (see note)                             | M       | M          |
| QAM random access uplink RF channel subslot (see note) | C       | -          |
| CRC pass/fail indication (see note)                    | -       | M          |
| Scrambling code (see note)                             | M       | -          |
| Report (see note)                                      | -       | C          |
| NOTE: Not sent over the air interface.                 |         |            |
| Key: M: Mandatory;<br>C: Conditional;<br>-: Not used.  |         |            |

**Table 23.3: Parameters used in the TMV-CONFIGURE primitive**

| Parameter  | Request<br>(see note) | Confirm<br>(see note) |
|--|-----------------------|-----------------------|
| Information about channel                                    | C                     | C                     |
| QAM slot format  | C                     | -                     |
| Scrambling code for reception                                | C                     | -                     |
| Energy economy or part-time reception or napping information | C                     | -                     |
| Signalling or traffic mode                                   | C                     | -                     |
| Second half slot stolen                                      | C                     | -                     |
| TCH type and interleaving depth                              | C                     | -                     |
| Monitoring pattern information                               | C                     | -                     |
| NOTE: Not sent over the air interface.                       |                       |                       |
| Key: M: Mandatory;<br>C: Conditional;<br>-: Not used.        |                       |                       |

The TMV-SAP boundary is defined to clarify the protocol description and does not imply any specific MS implementation. The word "shall" is used to describe this SAP and the primitives for traceability reasons in the protocol model, but they are not testable.

Many of the parameters exchanged at the TMV-SAP are not sent over the air interface but may be deduced from the physical layer transmission or reception. For example, the scrambling code is not sent as part of the information content, but modifies the information so that reception with a wrong scrambling code will generate an erroneous CRC and so the information will be discarded. On the contrary, reception with the correct scrambling code will only be affected by the transmission medium errors.

The MAC block is the SDU from the upper MAC. The size of the MAC block shall be equal to the appropriate SDU size for the logical channel being used. For C-plane signalling, the upper MAC shall assure this size by fragmenting/associating suitably and by using the Null PDU and/or fill bits to make the MAC block up to the required size. The required size for MAC blocks that may contain TMA-SAP C-plane signalling is shown in tables 23.4 and 23.5.

Table 23.4: Size of uplink MAC blocks that may contain TMA-SAP signalling

| Logical channel | Size of MAC block [bits] |
|-----------------|--------------------------|
| SCH/HU          | 92                       |
| SCH/F           | 268                      |
| STCH            | 124                      |
| SCH-P8/HU       | 148                      |
| SCH-P8/F        | 412                      |

| SCH-Q/D150-64H  | 4 133                    |
| SCH-Q/D150-64M  | 5 517                    |
| SCH-Q/D150-64U  | 8 288                    |
| SCH-Q/B150      | 1 161                    |

For U-plane signalling on STCH, the MAC block shall comprise a single MAC-U-SIGNAL PDU. For TCH, the MAC block shall comprise a single MAC-TRAFFIC PDU. (For TCH/S, this PDU contains one or two speech frames and, for circuit mode data, it contains data equivalent to a full slot.)

The scrambling code passed to the MAC by the MLE shall be a 24-bit field composed of the MCC and MNC as defined in ETSI EN 300 392-1 [6], clause 7. The MCC and MNC shall be part of the MLE information contained within the SYNC or SYNC-DA PDU broadcast by the BS on the BSCH or BSCH-Q respectively. The upper MAC shall add to this a 6-bit colour code which shall be contained in the SYNC or SYNC-DA PDU. The combination of MCC, MNC and colour code shall make up the scrambling code which the upper MAC shall pass to the lower MAC via the TMV-SAP. This scrambling code shall correspond to the extended colour code used for scrambling and de-scrambling in the lower MAC as defined in clause 8. The scrambling code shall correspond to the 30-bit extended colour code  $e(1)$ ,  $e(2)$ , ...,  $e(30)$  as shown in figure 23.5.

NOTE 2: The SYNC and SYNC-DA PDUs (broadcast on the BSCH and BSCH-Q respectively) are transmitted with all bits  $e(1)$ ,  $e(2)$ , ...,  $e(30)$  set equal to zero; see clause 8.

## 23.2.2 PDU mapping of the logical channels at the TMV-SAP

Logical channel definitions are given in clause 9 and an overview of their use may be found in clause 19.

Table 23.6 defines the mapping of the MAC PDUs defined in clause 21 onto the various logical channels.

**Table 23.6: Mapping of the MAC PDUs onto the logical channels**

| MAC PDU       | Logical channel(s)  | Note                     |
|---------------|---|--------------------------|
| ACCESS-ASSIGN | AACH, AACH-Q  | MAC internal information |
| ACCESS-DEFINE | SCH/HD, SCH/F, STCH, SCH-P8/HD, SCH-P8/F, SCH-Q/D, SCH-Q/B          |                          |
| QAM-SLOTINFO  | SICH-Q/D, SICH-Q/U  |                          |
| MAC-ACCESS    | SCH/HU, SCH-P8/HU, SCH-Q/RA, SCH-Q/HU                               | TMA-SAP information      |
| MAC-END-HU    | SCH/HU, SCH-P8/HU, SCH-Q/HU   |                          |
| MAC-DATA      | SCH/F, STCH, SCH-P8/F, SCH-Q/U                                      |                          |

| MAC-RESOURCE  | SCH/HD, SCH/F, STCH, SCH-P8/HD, SCH-P8/F, SCH-Q/D, SCH-Q/B          |                          |
| MAC-D-BLCK    | SCH/F, SCH-P8/F, SCH-Q/D, SCH-Q/B                                   |                          |
| MAC-FRAG      | SCH/HD, SCH/F, SCH-P8/HD, SCH-P8/F, SCH-Q/D, SCH-Q/U, SCH-Q/B       |                          |
| MAC-END       | SCH/HD, SCH/F, STCH, SCH-P8/HD, SCH-P8/F, SCH-Q/D, SCH-Q/U, SCH-Q/B |                          |
| MAC-TRAFFIC   | TCH   | TMD-SAP information      |
| MAC-U-SIGNAL  | STCH  |                          |
| SYNC          | BSCH  | TMB-SAP information      |
| SYNC-DA       | BSCH-Q  |                          |
| SYSINFO       | BNCH on SCH/HD, STCH, SCH-P8/HD, SCH-P8/F                           |                          |
| SYSINFO-Q     | BNCH-Q on SCH-Q/D   |                          |
| SYSINFO-DA    | BNCH-Q on SCH-Q/D or on SCH-Q/B, SCH/F, SCH-P8/HD, SCH-P8/F         |                          |

## 23.2.3 $\pi/4$ -DQPSK, D8PSK and QAM channels

There are three possible modulation modes for channels:

- $\pi/4$ -DQPSK;
- D8PSK; and
- QAM.

In the present document, the modulation mode of a common control channel is:

- $\pi/4$ -DQPSK for Conventional Access; or
- QAM for Direct Access.

An assigned channel may be allocated as a  $\pi/4$ -DQPSK, D8PSK or QAM channel.

The general signalling operation with the three modulation modes is described in the remainder of this clause.

### a) $\pi/4$ -DQPSK channel

All signalling and data messages and traffic on a  $\pi/4$ -DQPSK channel shall be sent using  $\pi/4$ -DQPSK modulation.

The bandwidth of a  $\pi/4$ -DQPSK channel is 25 kHz.

## b) D8PSK channel

A "D8PSK channel" is the generic term for a channel on which signalling and data messages may be sent using either  $\pi/4$ -DQPSK bursts or  $\pi/8$ -D8PSK bursts. The following restrictions apply:

- Random access messages shall be sent using the  $\pi/4$ -DQPSK control uplink burst.
- In frame 18, downlink slots for which  $(MN + TN) \bmod 4 = 1$  or 3 shall be sent using  $\pi/4$ -DQPSK bursts.

NOTE 1: BSCH (containing the SYNC PDU) + SCH/HD is mapped on a D8PSK channel in frame 18 if  $(MN + TN) \bmod 4 = 3$ ; BNCH (containing the SYSINFO PDU) is mapped on a D8PSK channel in frame 18 if  $(MN + TN) \bmod 4 = 1$ ; see clause 9.5.2. If the SYSINFO PDU is sent in other slots on a D8PSK channel, the BS may use either a  $\pi/4$ -DQPSK burst or a  $\pi/8$ -D8PSK burst.

For downlink transmissions on a D8PSK channel in the assigned slots in frames 1 to 17, and in the assigned slots in frame 18 for which  $(MN + TN) \bmod 4 = 2$  or 4, the BS chooses whether to use a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK burst on a slot-by-slot basis. A receiving MS shall determine whether a downlink slot contains a  $\pi/4$ -DQPSK normal downlink burst or a  $\pi/8$ -D8PSK normal downlink burst by determining whether normal training sequence 1 or normal training sequence 2 uses the  $\pi/4$ -DQPSK form or the  $\pi/8$ -D8PSK form (see clause 9.4.4.3.2).

NOTE 2: Thus there are four possible normal training sequences on the downlink of a D8PSK channel:

- normal training sequence 1 using the  $\pi/4$ -DQPSK form, indicating one logical channel (e.g. SCH/F) on the blocks 1 and 2 of the  $\pi/4$ -DQPSK normal downlink burst;
- normal training sequence 2 using the  $\pi/4$ -DQPSK form, indicating two logical channels (e.g. SCH/HD + SCH/HD) on the blocks 1 and 2 of the  $\pi/4$ -DQPSK normal downlink burst;
- normal training sequence 1 using the  $\pi/8$ -D8PSK form, indicating one logical channel (e.g. SCH-P8/F) on the blocks 1 and 2 of the  $\pi/8$ -D8PSK normal downlink burst;
- normal training sequence 2 using the  $\pi/8$ -D8PSK form, indicating two logical channels (e.g. SCH-P8/HD + SCH-P8/HD) on the blocks 1 and 2 of the  $\pi/8$ -D8PSK normal downlink burst.

NOTE 3: The ACCESS-ASSIGN PDU is sent using  $\pi/4$ -DQPSK modulation in all downlink slots i.e. in both  $\pi/4$ -DQPSK and  $\pi/8$ -D8PSK bursts (see clause 9.4.4.2). The ACCESS-ASSIGN PDU uses the AACH logical channel which is mapped onto the broadcast block.

Similarly, for reserved slots and subslots on the uplink of a D8PSK channel, the transmitting MS shall choose whether to use a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK burst in each slot or subslot (see clause 23.4.9). Then:

- the BS shall determine whether a reserved slot contains a  $\pi/4$ -DQPSK normal uplink burst or a  $\pi/8$ -D8PSK normal uplink burst by determining whether the normal training sequence uses the  $\pi/4$ -DQPSK form or the  $\pi/8$ -D8PSK form (see clause 9.4.4.3.2);
- the BS shall determine whether a reserved subslot contains a  $\pi/4$ -DQPSK control uplink burst or a  $\pi/8$ -D8PSK control uplink burst by determining whether the extended training sequence uses the  $\pi/4$ -DQPSK form or the  $\pi/8$ -D8PSK form (see clause 9.4.4.3.3).

The BS should look for a  $\pi/4$ -DQPSK control uplink burst in subslots that it has designated as being available for random access.

In the present document, the only usage of D8PSK channels is for assigned SCCH (see clause 23.3.1.2.2). The BS indicates that an allocated channel is a D8PSK channel when it sends the channel allocation.

The bandwidth of a D8PSK channel is 25 kHz.

The BS may allocate D8PSK channel(s) on the same carrier as  $\pi/4$ -DQPSK channel(s), in different timeslots - either on the main carrier (for CA) or on carriers other than the main carrier (for CA and DA).

## c) QAM channel

All signalling and data messages on a QAM channel shall be sent using QAM modulation.

Signalling and data messages on a QAM channel may use various combinations of modulation level and coding rate as follows:

- 4-QAM, coding rate = 1/2;
- 16-QAM, coding rate = 1/2;
- 16-QAM, coding rate = 1;
- 64-QAM, coding rate = 1/2;
- 64-QAM, coding rate = 2/3;
- 64-QAM, coding rate = 1.

All downlink bursts shall use the full bandwidth of the channel (25 kHz, 50 kHz, 100 kHz or 150 kHz). The BS shall choose which modulation level and coding rate to use for the SCH-Q/D on a slot-by-slot basis.

NOTE 4: There is a QAM Broadcast Network Channel BNCH-Q containing the SYSINFO-Q PDU (used by CA MSs). This is sent on SCH-Q/D in any slot in frames 1 to 18 on a QAM channel.

The QAM Broadcast Network Channel BNCH-Q may alternatively contain the SYSINFO-DA PDU (used by DA MSs). There is a fixed mapping of the SYSINFO-DA PDU on the DA main carrier. The SYSINFO-DA PDU may also be sent in other slots - on the DA main carrier and also on other QAM carriers.

There is a QAM Broadcast Synchronization Channel BSCH-Q containing the SYNC-DA PDU (used by DA MSs that are attempting to synchronize and obtain initial information about a DA cell). The downlink burst that carries the SYNC-DA PDU is the QAM Frequency Correction Burst (FCB), which always uses 4-QAM, coding rate = 1/2. There is a fixed mapping of the SYNC-DA PDU on the DA main carrier. It may also be sent in other slots - on the DA main carrier and also on other QAM carriers.

The fixed mappings of SYSINFO-DA and SYNC-DA on a DA main carrier are described in clause 9.

Downlink slots (except slots containing the BLCH-Q) contain the AACH-Q and SICH-Q/D logical channels, both of which always use 4-QAM, coding rate = 1/2. The AACH-Q may contain the ACCESS-ASSIGN PDU (see clause 21.4.7). The SICH-Q/D contains the downlink QAM-SLOTINFO PDU (see clause 21.4.8.2). The downlink QAM-SLOTINFO PDU indicates the format of the remainder of the downlink slot in which it appears. This format information includes the modulation level and coding rate, and indicates whether the burst is an FCB.

For the purposes of the protocol description: when an MS receives a downlink slot, the following "two-stage" method applies for decoding the slot:

- The lower MAC shall decode the AACH-Q and SICH-Q/D and pass the information to the upper MAC using TMV-UNITDATA indication primitives.
- The upper MAC shall use the ACCESS-ASSIGN PDU (when included within the AACH-Q) as described in other clauses within clause 23.
- The upper MAC shall process the QAM-SLOTINFO PDU.
- If the upper MAC understands the value of the "slot format" element in the QAM-SLOTINFO PDU and the MS is capable of processing slots with the indicated format then:
  - the upper MAC shall inform the lower MAC about the format of the remainder of the slot (including the modulation level and coding rate, and whether the burst is an FCB), using the TMV-CONFIGURE request primitive;
  - if the burst is not an FCB, the lower MAC shall decode the SCH-Q/D and pass the information to the upper MAC using the TMV-UNITDATA indication primitive;

- if the burst is an FCB:
  - the lower MAC in a DA MS may decode the BSCH-Q, and may pass the information to the upper MAC using the TMV-UNITDATA indication primitive (see note 7 and note 8);
  - if the bandwidth of the channel is 50 kHz, 100 kHz or 150 kHz, the lower MAC shall decode the SCH-Q/B and pass the information to the upper MAC using the TMV-UNITDATA indication primitive (see note 9).

Otherwise (i.e. if the upper MAC does not understand the value of the "slot format" element or the MS is not capable of processing slots with the indicated format) the upper MAC shall instruct the lower MAC not to continue processing the remainder of the slot, using the TMV-CONFIGURE request primitive.

NOTE 5: The MS may perform error detection on the SICH-Q/D. If the SICH-Q/D is not decodeable, the MS designer may choose an appropriate method for attempting to process the remainder of the slot; for example, the MS might attempt to process the remainder of the slot as 4-QAM, coding rate = 1/2. Alternatively the MS may decide not to continue processing the remainder of the slot.

NOTE 6: The MS is required to perform error detection on the AACH-Q. The MS actions if the AACH-Q is not decodeable are specified in other clauses within clause 23.

NOTE 7: The information in the SYNC-DA PDU is intended primarily for MSs that are attempting to synchronize with and obtain initial information about the DA cell. It is optional whether DA MSs already camped on the cell continue to decode the SYNC-DA PDU.

NOTE 8: The information in the SYNC-DA PDU is not appropriate to CA MSs.

NOTE 9: All MSs that understand the FCB value of the "slot format" element are required to decode the SCH-Q/B. However the BS designer should note that some CA MSs may not understand the FCB value of the "slot format" element.

NOTE 10: The BSCH-Q and SCH-Q/B logical channels always use 4-QAM, coding rate = 1/2.

When the MS sends a random access message, it shall use the logical channel SCH-Q/RA. This logical channel uses 4-QAM, coding rate = 1/2 in a random access uplink RF channel subslot with a 25 kHz bandwidth.

Reserved uplink slots and subslots shall use the full bandwidth of the channel (25 kHz, 50 kHz, 100 kHz or 150 kHz). The transmitting MS shall choose which modulation level and coding rate to use for the SCH-Q/U in each slot or SCH-Q/HU in each subslot (see clause 23.4.9) - subject to the maximum uplink modulation level permitted by the BS.

Reserved uplink slots and subslots contain the SICH-Q/U logical channel, which always uses 4-QAM, coding rate = 1/2. The SICH-Q/U contains the uplink QAM-SLOTINFO PDU (see clause 21.4.8.1). The uplink QAM-SLOTINFO PDU indicates the format (including the modulation level and coding rate) of the remainder of the uplink slot or subslot in which it appears.

When an BS receives a reserved slot or subslot, it should use a "two-stage" method for decoding the slot - similar to the method described above for an MS (except that AACH-Q and the ACCESS-ASSIGN PDU and BSCH-Q and SCH-Q/B do not apply on the uplink).

For both CA and DA, QAM channels may be used for assigned SCCH (see clause 23.3.1.2.2). The BS indicates that an allocated channel is a QAM channel when it sends the channel allocation. It also indicates the bandwidth of the channel and the maximum QAM modulation level that the MS is permitted to use on the uplink.

For DA, QAM channel(s) are also used for common control. The BS indicates the bandwidth of the common control channel(s) in the SYNC-DA and SYSINFO-DA PDUs. The BS also indicates (in the SYSINFO-DA PDU) the maximum QAM modulation level that the MS is permitted to use on the uplink of the common control channel.

The BS should not allocate a QAM channel on the same carrier as  $\pi/4$ -DQPSK or D8PSK channel(s). Similarly, the BS should not allocate a  $\pi/4$ -DQPSK or D8PSK channel on the same carrier as QAM channel(s).

## 23.3 Control channel usage

### 23.3.1 Control channel types

#### 23.3.1.0 General

This clause describes the MS procedures for using control channels.

#### 23.3.1.1 Main control channels

##### 23.3.1.1.1 Conventional Access (CA) and Direct Access (DA) cells

In the present document there are two types of cell: Conventional Access (CA) cells and Direct Access (DA) cells.

- a) In a CA cell, one 25 kHz phase modulation carrier is used as the main carrier. The MCCH is a single-slot  $\pi/4$ -DQPSK channel that occupies slot 1 of the main carrier in normal mode. The MCCH is used for common control signalling. The BS may also operate up to three single-slot  $\pi/4$ -DQPSK common secondary control channels ( $\pi/4$ -DQPSK common SCCHs) on the CA main carrier if it requires more capacity for common control signalling; each common SCCH is used by a different subset of the MS population.

A CA MS is an MS that is currently camped on a CA cell, so it receives a  $\pi/4$ -DQPSK common control channel (i.e. the MCCH or a  $\pi/4$ -DQPSK common SCCH) unless it is directed by the BS to an assigned channel - assigned for a circuit mode call or for secondary control.

The BS may allocate all four timeslots of a CA main carrier for traffic or assigned control. Minimum mode operation then applies, in which the method of MCCH operation is changed (see clause 23.3.3).

- b) In a DA cell, one QAM carrier is used as the main carrier. The bandwidth of a DA main carrier is 25 kHz, 50 kHz, 100 kHz or 150 kHz.

The MCCH-Q comprises one, two, three or four timeslots per TDMA frame, whereas a QAM common SCCH comprises only one timeslot per TDMA frame. For DA, if the BS wishes to use more than one slot for common control signalling, it may use either a single multi-slot MCCH-Q or multiple single-slot QAM common control channels.

NOTE 1: The BS cannot use QAM common SCCH(s) if it is using a multi-slot MCCH-Q.

A DA MS is an MS that is currently camped on a DA cell, so it receives a QAM common control channel (i.e. the MCCH-Q or a QAM common SCCH) unless it is directed by the BS to an assigned channel - assigned for secondary control or for a circuit mode call.

For DA, the BS may allocate the MCCH-Q physical channel(s) as a QAM assigned channel for some MSs that are camped on the cell. Then the MSs in common mode and the MSs in assigned mode share the channel (though in some cases using slightly different procedures). Similarly, the BS may allocate a physical channel used as a QAM common SCCH also as a QAM assigned channel for some MSs, with the channel shared between the MSs in common mode and the MSs in assigned mode.

NOTE 2: A phase modulation carrier is a carrier that is currently carrying  $\pi/4$ -DQPSK and/or D8PSK channels. A QAM carrier is a carrier that is currently carrying QAM channels.

NOTE 3: An assigned channel may be a  $\pi/4$ -DQPSK, D8PSK or QAM channel. It may be either a single-slot or a multi-slot channel.

NOTE 4: An MS may be both CA-capable and DA-capable. In that case it may sometimes be a CA MS and at other times a DA MS, depending on whether its current serving cell is a CA cell or a DA cell.

From the perception of the MS, at any one time it is camped on either a CA cell or a DA cell, and it receives MLE broadcasts from the BS indicating which channel classes and/or irregular channels are available on that cell.

However, for cells that:

- are radiated from the same physical location or from locations sufficiently close together to permit sharing of eccentric channels; and
- share the same MCC, MNC, colour code and static cipher key or common cipher key (see ETSI EN 300 392-7 [8]);

there may be some flexibility in how channels are assigned. If wished, the same channel could be used by more than one cell as an assigned channel, provided that the shared channel is radiated from the same physical location as the cells or within the permitted separation for eccentric channels (i.e. if the assigned channel's transmitter site is within 4 km of the main carrier's transmitter site for each of the sharing cells - see clause 7.7). Therefore more than one cell may send MLE serving cell broadcasts about channel classes and irregular channels where those broadcasts relate to the same channels. Then:

- MSs camped on a CA cell may be assigned to a channel used also by DA MSs. For example:
  - A channel on a carrier other than either main carrier may be used as an assigned channel shared by both CA MSs and DA MSs. This may apply for both phase modulation carriers and QAM carriers.
  - If a channel on either main carrier is not being used for common control, it may be used as an assigned channel shared by both CA MSs and DA MSs.
  - The MCCH-Q or a QAM common SCCH may be used as an assigned channel for CA MSs. As outlined above, the MCCH-Q or a QAM common SCCH may also be used as an assigned channel for DA MSs camped on the DA cell. Thus the channel could be shared between the DA MSs in common mode, DA MSs in assigned mode and CA MSs in assigned mode.
- In some cases, DA MSs may be assigned to a channel used also by DA MSs that are camped on a different DA cell:
  - A channel on a carrier other than either DA main carrier may be used as an assigned channel shared by MSs from different DA cells. (The channel could also be shared by MSs from a CA cell.)

The present document does not support use of any channel on a DA main carrier as an assigned channel for MSs that are camped on a different DA cell.

NOTE 5: If an assigned channel is shared by MSs from different DA cells, the BS should not send the SYSINFO-DA or SYNC-DA PDU on that assigned channel.

NOTE 6: If the BS sends a group-addressed instruction to return to the appropriate common control channel to a group that includes MSs from more than one cell (CA cell or DA cell(s)) sharing the assigned channel, it should use a non-augmented channel allocation (in which case DA MSs use the main carrier information from the last received SYSINFO-DA or SYNC-DA PDU); see clause 23.5.4.

NOTE 7: Therefore, if an assigned channel is shared by MSs from different DA cells, and a DA main carrier is moved while some MSs from that cell are on the assigned channel, the BS should not use a group address that includes MSs from more than one cell sharing the channel when it instructs the MSs to return to the appropriate common control channel.

NOTE 8: The present document does not provide a general method for sharing of an assigned channel by MSs from different CA cells. However, annex S notes a restricted method that SwMIs may be able to use without the MSs being aware of the usage.

### 23.3.1.1.2 MCCH

In each CA cell, one 25 kHz RF carrier shall be defined as the main carrier frequency which shall be broadcast in the SYSINFO PDU on the Broadcast Network Channel BNCH (or, on a QAM channel, in the SYSINFO-Q PDU on the QAM Broadcast Network Channel BNCH-Q). The MCCH shall occupy slot 1 of the main carrier frequency of a BS in normal mode. A CA MS shall locate and receive the downlink MCCH, unless the BS has allocated any common SCCHs.

Signalling and data messages on the MCCH are sent using  $\pi/4$ -DQPSK modulation.

The BS shall use SCH/HD, SCH/F, BNCH and BSCH for transmitting signalling and data messages on the downlink of the MCCH. An MS shall attempt to receive and decode any paging messages on the downlink MCCH addressed to that individual MS or to one of the MS's valid group addresses. An MS shall also attempt to receive and decode any broadcast signalling messages sent on the downlink of the MCCH.

NOTE 1: Energy economy or dual watch mode and the cell reselection procedures may take precedence over the requirements on the MS to attempt to receive and decode paging messages and broadcast messages on the MCCH, or on a common SCCH.

For uplink access on the MCCH, the MS shall follow the random access and reserved access procedures described in clauses 23.5.1 and 23.5.2 respectively. The MS shall use SCH/HU for random access on the uplink of the MCCH and shall use SCH/HU or SCH/F for reserved access on the uplink of the MCCH. The uplink shall occupy only a single slot per TDMA frame (i.e. slot 1) for reserved access but may use an extended uplink channel for random access purposes if indicated by the ACCESS-DEFINE or SYSINFO PDU.

The downlink of the MCCH shall not be extended to more than a single slot per TDMA frame. A BS in normal mode shall always have an MCCH. However, a BS may assign the MCCH for use as a  $\pi/4$ -DQPSK traffic or assigned control channel in which case the BS enters minimum mode.

The ACCESS-ASSIGN PDU in the AACH in frames 1 to 17 shall indicate common control in the downlink direction for an MCCH. The ACCESS-ASSIGN PDU in frames 1 to 17 for the MCCH shall contain one of the following:

- a) Header value =  $00_2$ :
  - This is the normal case for an MCCH in which both the uplink and downlink are used for common control. "Field 1" shall indicate the access parameters for subslot 1 and "field 2" shall indicate the access parameters for subslot 2 of the uplink.
- b) Header value =  $01_2$  and "field 1" = UMc ( $000010_2$ ):
  - The BS may assign the uplink of the MCCH as a  $\pi/4$ -DQPSK assigned SCCH while still maintaining the MCCH on the downlink. In this case, the uplink may be shared between common control and assigned control. "Field 2" shall contain the access parameters for both of the uplink subslots and shall apply to both common and assigned control channels.

NOTE 2: The present document does not support use of UMr ( $000011_2$ ) on a phase modulation channel.

- c) Header value =  $10_2$  and "field 1" = UMc ( $000010_2$ ):
  - This is the same as for case b) above except that the random access parameters in "field 2" shall apply only for MSs using the uplink for assigned control. Any MS in common control mode shall not use the uplink for random access in this case.
- d) Header value =  $11_2$  and "field 1" = UMc ( $000010_2$ ) and "field 2" = UMt ( $xxxxxx_2$ ):
  - The BS may assign the uplink of the MCCH for transmission of traffic while still maintaining the MCCH on the downlink. "Field 2" shall contain the traffic usage marker for the uplink assigned channel.
- e) Header value =  $11_2$  and "field 1" = UMx ( $000000_2$ ) and "field 2" = UMx ( $000000_2$ ):
  - The BS may indicate that the MCCH on its main carrier has been deallocated and is no longer available for downlink or uplink signalling purposes. If N.215 successive ACCESS-ASSIGN PDUs received in frames 1 to 17 contain these values, then the MS-MAC should inform the higher layers of the de-allocation using a "common channel deallocated" TMC-REPORT indication primitive (indicating a downlink failure) in order to initiate the MLE cell reselection procedures.

The ACCESS-ASSIGN PDU in the AACH for frame 18 shall only indicate the uplink access rights. During normal mode operation, it shall always be assumed that slot 1 on the downlink is for common control as part of the MCCH. Any of the possible header values may be used during frame 18 for an MCCH.

### 23.3.1.1.3 MCCH-Q

In each DA cell, one RF carrier shall be defined as the main carrier frequency which shall be broadcast in the SYNC-DA PDU (when the PDU is sent on a QAM carrier other than the DA main carrier) and in the SYSINFO-DA PDU. The bandwidth of the DA main carrier is 25 kHz, 50 kHz, 100 kHz or 150 kHz.

The MCCH-Q may be one slot wide or alternatively may be a multi-slot channel i.e. two, three or four slots wide. The BS broadcasts the number of slots comprising the MCCH-Q in the SYSINFO-DA PDU.

- A single-slot MCCH-Q shall occupy slot 1 of the main carrier frequency.
- A two-slot MCCH-Q shall occupy slots 1 and 2 of the main carrier frequency.
- A three-slot MCCH-Q shall occupy slots 1, 2 and 3 of the main carrier frequency.
- A four-slot MCCH-Q shall occupy slots 1, 2, 3 and 4 of the main carrier frequency.

A DA MS shall locate and receive the downlink MCCH-Q, unless the BS has allocated any common SCCHs.

Signalling and data messages on the MCCH-Q are sent using QAM modulation.

The BS shall use SCH-Q/D, SCH-Q/B, BNCH-Q and BSCH-Q for transmitting signalling and data messages on the downlink of the MCCH-Q. An MS shall attempt to receive and decode any paging messages on the downlink MCCH-Q addressed to that individual MS or to one of the MS's valid group addresses. An MS shall also attempt to receive and decode any broadcast signalling messages sent on the downlink of the MCCH-Q.

NOTE 1: Energy economy or dual watch mode and the cell reselection procedures may take precedence over the requirements on the MS to attempt to receive and decode paging messages and broadcast messages on the MCCH-Q (single-slot or multi-slot MCCH-Q), or on a common SCCH. Also, part-time reception mode may take precedence over the requirements on the MS to attempt to receive and decode paging messages and broadcast messages on a multi-slot MCCH-Q.

For uplink access on the MCCH-Q, the MS shall follow the random access and reserved access procedures described in clauses 23.5.1 and 23.5.2 respectively. The MS shall use SCH-Q/RA for random access on the uplink of the MCCH-Q and shall use SCH-Q/HU or SCH-Q/U for reserved access on the uplink of the MCCH-Q. The uplink for reserved access shall occupy the same-numbered slots as the downlink of the MCCH-Q. An extended uplink channel may be used for random access purposes if indicated by the ACCESS-DEFINE or SYSINFO-DA PDU.

For DA, the BS shall have an MCCH-Q. However, the BS may allocate the MCCH-Q physical channel(s) as an assigned SCCH for some MSs (CA MSs and/or DA MSs), in which case the physical resource is shared between the MSs in common mode and the MSs in assigned mode.

NOTE 2: Minimum mode is not supported for DA.

The ACCESS-ASSIGN PDU in the AACH-Q in frames 1 to 17 shall indicate common control or common and assigned control in the downlink direction for an MCCH-Q. The ACCESS-ASSIGN PDU in frames 1 to 17 for the MCCH-Q shall contain one of the following:

- a) Header value =  $00_2$ :
  - This is the case for an MCCH-Q in which both the uplink and downlink are used exclusively for common control. "Field 1" shall indicate the access parameters for subslot 1 and "field 2" shall indicate the access parameters for subslot 2 of the uplink.
- b) Header value =  $01_2$  and "field 1" = UMr ( $000011_2$ ):
  - The BS may assign the physical channel(s) used for the MCCH-Q as a QAM assigned SCCH while still maintaining the MCCH-Q for MSs in common control mode. In this case, the uplink may be shared between common control and assigned control. "Field 2" shall contain the access parameters for both of the uplink subslots and shall apply to both common and assigned control channels.

- c) Header value =  $10_2$  and "field 1" = UMr (000011<sub>2</sub>):
- This is the same as for case b) above except that the random access parameters in "field 2" shall apply only for MSs using the channel for assigned control. Any MS in common control mode shall not use the uplink for random access in this case.
- d) Header value =  $11_2$  and "field 1" = UMx (000000<sub>2</sub>) and "field 2" = UMx (000000<sub>2</sub>):
- The BS may indicate that the MCCH-Q on its main carrier has been deallocated and is no longer available for downlink or uplink signalling purposes. If N.215 successive ACCESS-ASSIGN PDUs received in frames 1 to 17 contain these values, then the MS-MAC should inform the higher layers of the de-allocation using a "common channel deallocated" TMC-REPORT indication primitive (indicating a downlink failure) in order to initiate the MLE cell reselection procedures.

The ACCESS-ASSIGN PDU in the AACH-Q for frame 18 shall only indicate the uplink access rights. Any of header values  $00_2$ ,  $01_2$  and  $10_2$  may be used during frame 18 for an MCCH-Q.

NOTE 3: When sent on a QAM channel, the ACCESS-ASSIGN PDU uses the AACH-Q logical channel. The AACH-Q is sent by the BS in every downlink slot of a QAM channel (except slots containing BLCH-Q). However the ACCESS-ASSIGN PDU is present in the AACH-Q only if the "AACH-Q mode" element is set to 0 (see clause 21.4.7.1). In the present document, the BS should set the "AACH-Q mode" element to 0. However, in future editions of the present document, the BS may set the "AACH-Q mode" element to 1 in some slots; therefore, the MS should expect that the ACCESS-ASSIGN PDU may not be present in the AACH-Q.

The BS may change the number of slots comprising the MCCH-Q by modifying the appropriate parameter in the SYSINFO-DA PDU. A DA MS shall decode the SYSINFO-DA PDU and recognize if the number of slots comprising the MCCH-Q has changed. When decreasing the number of slots used for the MCCH-Q the BS shall not change its MCCH-Q configuration before first transmitting the new configuration in the SYSINFO-DA PDU. When increasing the number of slots used for the MCCH-Q the BS shall change its MCCH-Q configuration and then transmit the new configuration in the SYSINFO-DA PDU.

## 23.3.1.2 SCCH

### 23.3.1.2.0 Introduction

The BS may designate a secondary control channel (SCCH) for use as a main control channel by a subset of the user population. Alternatively, an SCCH may be allocated to certain MSs for subsequent data transfer. These two cases will subsequently be referred to as common and assigned SCCHs respectively.

### 23.3.1.2.1 Common SCCH

#### 23.3.1.2.1.1 General

For CA, the BS may designate up to three  $\pi/4$ -DQPSK common SCCHs for use as a main control channel by a subset of the CA MSs, as described in clause 23.3.1.2.1.2.

For DA, if the BS has a single-slot MCCH-Q, it may designate up to three QAM common SCCHs for use as a main control channel by a subset of the DA MSs, as described in clause 23.3.1.2.1.3.

NOTE: The BS cannot provide QAM common SCCH(s) if it has a multi-slot MCCH-Q.

#### 23.3.1.2.1.2 $\pi/4$ -DQPSK common SCCH

For CA, the BS may operate up to three common SCCHs for the purposes of common control signalling. Common SCCHs shall each occupy only one slot capacity on the main carrier and shall be used as the main control channel by a subset of the CA population. Therefore, a BS may operate up to a maximum of three common SCCHs in addition to the MCCH.

For CA, signalling and data messages on a common SCCH are sent using  $\pi/4$ -DQPSK modulation.

The BS shall indicate the number of common SCCHs in operation on the main carrier by setting a two-bit field in the SYSINFO PDU transmitted on BNCH (or, on any QAM channels, in the SYSINFO-Q PDU transmitted on BNCH-Q). This two-bit field maps to the number of common SCCHs in operation on this BS. If no common SCCHs are in operation, only the MCCH in slot 1 shall be available for common control signalling on the main carrier. If one common SCCH is indicated by the SYSINFO (or SYSINFO-Q) PDU, then slot 2 of the main carrier shall be used for this SCCH. If two SCCHs are in operation, slots 2 and 3 shall be used and if three SCCHs are in operation, slots 2, 3 and 4 shall be used.

In idle mode, a CA MS shall receive either the MCCH (slot 1) or one of the common SCCHs on the main carrier. Therefore, a CA MS shall receive one of the four downlink slots on the main carrier for common control purposes. On registration or at subscription, an MS receives a parameter which indicates to the MS which one of the downlink slots on the main carrier shall be used. If an MS has received this value at subscription and then also is assigned a value at registration, the value given at registration shall be used. The following rule shall then be applied by the MS:

- $N\_SCCH$  = number of common SCCHs in operation on CA main carrier:
  - two-bit field transmitted by BS in the SYSINFO (or SYSINFO-Q) PDU, value = 0 to 3;
- $MS\_SCCH$  = MS SCCH allocation:
  - four-bit field transmitted by BS to MS at registration or received by MS at subscription, value = 0 to 11 (eleven);
- Main carrier downlink slot =  $1 + (MS\_SCCH \bmod (N\_SCCH + 1))$ :
  - value = 1 to 4;

where mod = remainder after integer division.

This rule enables a CA MS to derive the slot that shall be used on the main carrier from its  $MS\_SCCH$  parameter received at registration or subscription and the number of common SCCHs currently in operation as indicated by the BS in the SYSINFO PDU. If the MS does not have a value of  $MS\_SCCH$  on this network, and has no value from subscription, it shall use the MCCH (i.e. slot 1 on the main carrier).

NOTE: Subscription is applicable only for the MS's home network.

The BS may change the number of common SCCHs by modifying the  $N\_SCCH$  parameter. An MS shall decode the SYSINFO PDU and recognize if  $N\_SCCH$  has changed. If  $N\_SCCH$  has changed the MS shall re-calculate, according to the above rule, the main carrier slot that it should use for common control signalling. When decreasing the number of common control channels the BS shall not change its SCCH configuration before first transmitting the new configuration in the SYSINFO PDU. When increasing the number of common control channels the BS shall change its SCCH configuration and then transmit the new configuration in the SYSINFO PDU.

A common SCCH, like the MCCH, shall always occupy only one slot per TDMA frame on the downlink of the main carrier. The uplink shall occupy only one slot per TDMA frame for reserved access but may use an extended uplink channel for random access purposes if indicated by the ACCESS-DEFINE or SYSINFO PDU (see clause 23.5.1 for more detailed explanation of random access procedures).

A CA MS returning to the common control channel after, for example, a traffic channel assignment, shall return to the MCCH or common SCCH that it was using before the assignment unless it has received, in the meantime, a SYSINFO or SYSINFO-Q PDU indicating a change in the SCCH configuration. (An MS may return to the common control channel due to the MS deciding to leave the call or as a result of receiving a MAC-RESOURCE or MAC-END PDU with a "Timeslot assigned" value of  $0000_2$  to indicate that it should go to the MCCH or appropriate common SCCH.) In this case it shall return to the main carrier slot defined by the new configuration. When decreasing the number of common control channels the BS should transmit the SYSINFO PDU in all slots of frame 18 on  $\pi/4$ -DQPSK and D8PSK channels, and should transmit the SYSINFO-Q PDU on any QAM channels, before changing the SCCH configuration to ensure that all CA MSs including those on assigned channels receive the configuration change. When increasing the number of common control channels the BS should change its SCCH configuration and then transmit the new configuration in the SYSINFO PDU (and in the SYSINFO-Q PDU on any QAM channels).

The ACCESS-ASSIGN PDU for a  $\pi/4$ -DQPSK common SCCH shall contain one of the combinations of elements a) to e) as described for the MCCH during frames 1 to 17 and shall follow the same rules defined for the MCCH for frame 18.

### 23.3.1.2.1.3 QAM common SCCH

In a DA cell, the MCCH-Q may be one, two, three or four slots wide.

If the BS is using a single-slot MCCH-Q, it may operate up to three common SCCHs for the purposes of common control signalling. Common SCCHs shall each occupy only one slot capacity on the main carrier and shall be used as the main control channel by a subset of the DA population. Therefore, the BS may operate up to a maximum of three common SCCHs in addition to a single-slot MCCH-Q.

NOTE 1: Thus, for DA, if the BS wishes to use more than one slot for common control signalling, it may use either a single multi-slot MCCH-Q or multiple single-slot common control channels. (The BS cannot use common SCCH(s) if it is using a multi-slot MCCH-Q.)

For DA, signalling and data messages on a common SCCH are sent using QAM modulation.

The BS shall indicate whether common SCCHs are in operation on the main carrier by setting a one-bit field in the SYSINFO-DA PDU. If common SCCHs are being used, the BS shall indicate the number of common SCCHs in operation by setting a two-bit field in the SYSINFO-DA PDU; this two-bit field maps to the number of common SCCHs in operation on this BS.

If one common SCCH is indicated by the SYSINFO-DA PDU, then slot 2 of the main carrier shall be used for this SCCH. If two SCCHs are in operation, slots 2 and 3 shall be used and if three SCCHs are in operation, slots 2, 3 and 4 shall be used.

In idle mode, a DA MS shall receive either the MCCH-Q or one of the common SCCHs on the main carrier.

On registration or at subscription, a DA MS receives a parameter which indicates to the MS which one of the downlink slots on the main carrier shall be used when common SCCHs are in operation. If an MS has received this value at subscription and then also is assigned a value at registration, the value given at registration shall be used. The following rule shall then be applied by the MS when common SCCHs are in operation:

- $N\_SCCH-Q$  = number of common SCCHs in operation on DA main carrier:
  - from the two-bit field transmitted by BS in the SYSINFO-DA PDU, value = 1 to 3;
- $MS\_SCCH$  = MS SCCH allocation:
  - four-bit field transmitted by BS to MS at registration or received by MS at subscription, value = 0 to 11 (eleven);
- Main carrier downlink slot =  $1 + (MS\_SCCH \bmod (N\_SCCH-Q + 1))$ :
  - value = 1 to 4;

where mod = remainder after integer division.

This rule enables a DA MS to derive the slot that shall be used on the main carrier when common SCCHs are in operation from its  $MS\_SCCH$  parameter received at registration or subscription and the information about the number of common SCCHs currently in operation as indicated by the BS in the SYSINFO-DA PDU. If the MS does not have a value of  $MS\_SCCH$  on this network, and has no value from subscription, it shall use the MCCH-Q.

NOTE 2: Subscription is applicable only for the MS's home network.

The BS may change the number of common SCCHs by modifying the  $N\_SCCH-Q$  parameter. An MS shall decode the SYSINFO-DA PDU and recognize if the number of common SCCHs has changed. If the number of common SCCHs has changed the MS shall re-calculate, according to the above rule, the main carrier slot that it should use for common control signalling. When decreasing the number of slots used for common control signalling the BS shall not change its SCCH configuration before first transmitting the new configuration in the SYSINFO-DA PDU. When increasing the number of slots used for common control signalling the BS shall change its SCCH configuration and then transmit the new configuration in the SYSINFO-DA PDU.

A common SCCH shall always occupy only one slot per TDMA frame on the downlink of the main carrier. The uplink shall occupy only one slot per TDMA frame for reserved access but may use an extended uplink channel for random access purposes if indicated by the ACCESS-DEFINE or SYSINFO-DA PDU (see clause 23.5.1 for more detailed explanation of random access procedures).

A DA MS returning to the common control channel after a channel assignment shall return to the MCCH-Q or common SCCH that it was using before the assignment unless it has received, in the meantime, a SYSINFO-DA PDU indicating a change in the common control channel configuration. (An MS may return to the common control channel due to the MS deciding to leave the assigned channel or as a result of receiving a MAC-RESOURCE or MAC-END PDU with a "Timeslot assigned" value of 0000<sub>2</sub> to indicate that it should go to the appropriate common control channel.) In this case it shall return to the common control channel defined by the new configuration. When decreasing the number of slots used for common control signalling the BS should transmit the SYSINFO-DA PDU on QAM channels (and may transmit the SYSINFO-DA PDU on any  $\pi/4$ -DQPSK and D8PSK channels), before changing the common control channel configuration to ensure that all DA MSs including those on assigned channels receive the configuration change. When increasing the number of slots used for common control signalling the BS should change its common control channel configuration and then transmit the new configuration in the SYSINFO-DA PDU.

The ACCESS-ASSIGN PDU for a QAM common SCCH shall contain one of the combinations of elements a) to d) as described for the MCCH-Q during frames 1 to 17 and shall follow the same rules defined for the MCCH-Q for frame 18.

### 23.3.1.2.2 Assigned SCCH

An SCCH may be assigned by the BS for subsequent data transfer in response to an initial random access or after an initial paging message on its common control channel (i.e. on the MCCH or MCCH-Q, or the appropriate  $\pi/4$ -DQPSK or QAM common SCCH). This type of SCCH is referred to as an assigned SCCH. An MS shall be directed to an assigned SCCH by a MAC-RESOURCE or MAC-END PDU (see clause 21) transmitted by the BS. The assigned SCCH may be used by a certain group of MSs for a particular signalling message or data exchange (e.g. packet data); or it may be shared between several MSs each with intermittent bursts of signalling to send.

NOTE 1: The BS may use an assigned SCCH as a general packet data channel supporting advanced links for several MSs, where each MS may be intermittently offering data packets.

An assigned SCCH may be allocated as a  $\pi/4$ -DQPSK, D8PSK or QAM channel - as indicated by the "channel allocation" element in the MAC-RESOURCE or MAC-END PDU. The bandwidth of a  $\pi/4$ -DQPSK or D8PSK assigned SCCH is 25 kHz. The bandwidth of a QAM assigned SCCH is 25 kHz, 50 kHz, 100 kHz or 150 kHz - as indicated by the "channel allocation" element in the MAC-RESOURCE or MAC-END PDU.

An assigned SCCH may be allocated as occupying up to four slots per TDMA frame as indicated by the MAC-RESOURCE or MAC-END PDU. If both the uplink and downlink are assigned for this purpose then the uplink for reserved access shall occupy the same-numbered slots as the downlink; i.e. an assigned SCCH cannot be allocated with a different number of slots for the uplink for reserved access and downlink. (An extended uplink channel may be used for random access purposes if indicated by the ACCESS-DEFINE PDU.)

The number of slots allocated to a particular assigned SCCH by the BS may be increased or decreased by sending a MAC-RESOURCE (or MAC-END) PDU on the assigned SCCH.

An MS shall attempt to receive and decode all downlink signalling transmitted by the BS on all allocated slots of an assigned SCCH (within the constraints of the napping procedures and the cell reselection procedures, and linearization and transmission requirements). Similarly, the MS may transmit uplink signalling on all allocated slots of the uplink of an assigned SCCH in accordance with the random access and reserved access procedures defined in clauses 23.5.1 and 23.5.2 respectively.

NOTE 2: The MS may operate with multi-slot channels without the need for the MS to support frequency full duplex operation. These MS capabilities are indicated in the mobile class ("class of MS" element, see clause 16). If an MS is not frequency full duplex and is operating on a multi-slot channel, the BS should not send signalling messages to that MS when the MS is transmitting in reserved slots or switching from receive to transmit or from transmit to receive.

If the BS allocates an assigned SCCH on the downlink, the ACCESS-ASSIGN PDU (when present) in frames 1 to 17 shall contain a header value of 01<sub>2</sub>, 10<sub>2</sub> or 11<sub>2</sub> and:

- "field 1" shall be equal to UMa (000001<sub>2</sub>) for a  $\pi/4$ -DQPSK or D8PSK assigned SCCH;
- "field 1" shall be equal to UMa (000001<sub>2</sub>) or UMr (000011<sub>2</sub>) for a QAM assigned SCCH.

If the BS allocates an assigned SCCH in the uplink direction, the ACCESS-ASSIGN PDU (when present) in frames 1 to 17 shall contain a header value of  $01_2$  or  $10_2$  depending on whether the uplink is also to be shared with common control uplink accesses. For a unidirectional assigned SCCH, any control slots in the opposite direction shall also be part of the assigned SCCH for the purposes of applying the general procedures for transmission and reception of signalling messages.

If the BS allocates an assigned SCCH in both directions, the ACCESS-ASSIGN PDU (when present) in frames 1 to 17 shall contain a header value of  $01_2$  or  $10_2$  depending on whether the uplink is also to be shared with common control uplink accesses. "Field 1" shall be set as indicated above.

NOTE 3: In the present document, a D8PSK or QAM assigned SCCH is always allocated in both directions. However, in future editions of the present document, the BS may be permitted to allocate a D8PSK or QAM assigned SCCH in only one direction. Therefore the MS should expect that a D8PSK or QAM assigned SCCH may be allocated in only one direction.

The assigned slot(s) during frame 18 may be used for any combination of common or assigned control signalling on the downlink, and the ACCESS-ASSIGN PDU (when present) shall indicate the uplink access restrictions.

NOTE 4: When sent on a  $\pi/4$ -DQPSK or D8PSK channel, the ACCESS-ASSIGN PDU uses the AACH logical channel; the ACCESS-ASSIGN PDU is sent by the BS in every downlink slot.

When sent on a QAM channel, the ACCESS-ASSIGN PDU uses the AACH-Q logical channel. The AACH-Q is sent by the BS in every downlink slot of a QAM channel (except slots containing BLCH-Q). However the ACCESS-ASSIGN PDU is present in the AACH-Q only if the "AACH-Q mode" element is set to 0 (see clause 21.4.7.1). In the present document, the BS should set the "AACH-Q mode" element to 0. However, in future editions of the present document, the BS may set the "AACH-Q mode" element to 1 in some slots. Therefore, the MS should expect that the ACCESS-ASSIGN PDU may not be present in the AACH-Q.

The BS shall always transmit in the downlink slots of an assigned SCCH except during a BLCH or BLCH-Q. This applies even while there is no signalling information to send. (The BS may send broadcast PDUs (except the SYNC PDU) or Null PDUs during these times.) This is required in order for the MS to carry out correctly its channel maintenance procedures for an assigned channel.

NOTE 5: The BS should send the SYNC PDU on a  $\pi/4$ -DQPSK common control channel or on a  $\pi/4$ -DQPSK or D8PSK assigned channel only in the defined positions, which are in frame 18 (see clause 9); this is because the SYNC PDU is sent with the synchronization training sequence. The SYNC PDU is not used on a QAM channel.

For DA, the BS may send the SYNC-DA PDU on QAM channels at any time (for example, when there is no signalling information to send), in addition to the defined positions on the DA main carrier. (This is possible because the QAM-SLOTINFO PDU indicates whether each downlink burst is an FCB.)

### 23.3.1.3 ACCH

An ACCH is a control channel associated with an assigned traffic channel. There shall be two types of ACCH dependent on the current usage of the assigned channel. When the uplink or downlink of the assigned channel are not in use for traffic, the corresponding assigned slots in frames 1 to 18 shall be available for control signalling. This control channel is known as a Fast Associated Control Channel (FACCH). When the assigned channel is carrying traffic either in the uplink or downlink direction, only frame 18 is available for control signalling in that direction. This control channel is known as a Slow Associated Control Channel (SACCH).

NOTE 1: A traffic channel may be allocated as bidirectional but sometimes may only carry traffic either in the uplink or downlink direction e.g. for an inter-site call. Then the opposite direction is a FACCH. In this case, therefore, a FACCH will be available in one direction and a SACCH in the other direction.

NOTE 2: When an assigned channel is carrying traffic either in the uplink or downlink direction then, in addition to the SACCH in that direction, capacity may be "stolen" from the circuit in frames 1 to 17 for signalling purposes, without changing the mode of operation (see clause 23.8). Stealing uses the STCH logical channel, whereas the FACCH and SACCH are mapped onto SCH.

An ACCH shall have the same modulation as the associated traffic channel. Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels. Therefore signalling messages on an ACCH are sent using  $\pi/4$ -DQPSK modulation.

An ACCH shall have the same number of slots per TDMA frame as the associated traffic channel. The uplink and downlink shall have an equal number of slots per TDMA frame (see note 3). Therefore, for a multi-slot traffic channel, the ACCH shall assume the same uplink and downlink slot allocation as assigned for the traffic channel (see note 3).

NOTE 3: The exception is that an extended uplink channel may be used for random access purposes if indicated by the ACCESS-DEFINE PDU.

A receiving MS shall attempt to receive and decode all of the downlink slots of an ACCH (within the constraints of the napping procedures and the cell reselection procedures, and linearization and transmission requirements) to receive any addressed messages from the BS for that MS. An MS shall also receive any broadcast messages on the downlink ACCH.

As an option, if the BS indicates that frame 18 extension is allowed (indicated by the "frame 18 extension" element in the SYNC PDU), an MS may receive and decode PDUs on all four slots of frame 18. However, the MS should not attempt to reconstruct any fragmented PDUs on frame 18 slots other than the ACCH for that MS. This restriction applies because an MS cannot know in which slot subsequent fragments will be sent for slots other than the ACCH for that MS. The MS shall not attempt to use random access transmission on slots of frame 18 other than its own ACCH (unless permitted by the "timeslot pointer" element from its own ACCH). The application of the normal procedures for transmission and reception of signalling messages shall apply only to the ACCH (i.e. FACCH and/or SACCH) as indicated by the "timeslot assigned" element in the channel allocation.

An MS transmitting in traffic mode shall attempt to receive and decode downlink slots in frames 1 to 17 when required by the assigned monitoring pattern(s) (given with the channel allocation). This allows the BS to send signalling, for example using the STCH, to a transmitting MS. The MS shall only be expected to adhere to the assigned monitoring pattern(s) within its duplex and switching capability (see clause 23.3.1.4).

An MS transmitting in traffic mode shall attempt to receive and decode the ACCH in frame 18 when required by the assigned monitoring pattern(s). For multi-slot operation, the MS shall attempt to receive and decode at least the highest numbered downlink slot allocated for the circuit mode call in frame 18. (The MS shall also be capable of transmitting in the highest numbered uplink slot in frame 18 in case it has to respond to a paging message from the BS.) Similarly, an MS receiving in traffic mode shall attempt to receive and decode at least the lowest numbered slot allocated for the circuit mode call in frame 18 for SACCH downlink signalling (and it shall be capable of transmitting uplink signalling during the lowest numbered slot in frame 18).

NOTE 4: This means that the MS may operate with multi-slot channels without the need for the MS to support frequency full duplex operation.

When the MS switches out of traffic mode, it shall attempt to receive and decode all allocated slots for downlink ACCH signalling (within the constraints of the napping procedures and the cell reselection procedures, and linearization and transmission requirements). Similarly, any of the allocated slots may be used for uplink signalling in accordance with the MAC random access and reserved access procedures.

In the case of a downlink FACCH, the ACCESS-ASSIGN PDU in frames 1 to 17 shall contain a header value of  $01_2$ ,  $10_2$  or  $11_2$  and "field 1" shall be equal to UMa (000001<sub>2</sub>). In the case of an uplink FACCH, the ACCESS-ASSIGN PDU in frames 1 to 17 shall contain a header value of  $01_2$  or  $10_2$  depending on whether the uplink is also to be shared with common control uplink accesses.

In the case of a bidirectional FACCH, the ACCESS-ASSIGN PDU in frames 1 to 17 shall contain a header value of  $01_2$  or  $10_2$  depending on whether the uplink is also to be shared with common control uplink accesses.

The ACCH in frame 18 may be used for any combination of common or assigned control signalling on the downlink and the ACCESS-ASSIGN PDU shall indicate the uplink access restrictions.

The BS shall always transmit in the downlink slots of an ACCH except during a BLCH. This applies even while there is no signalling information to send. (The BS may send broadcast PDUs (except the SYNC PDU) or Null PDUs during these times.) This is required in order for the MS to carry out correctly its channel maintenance procedures for an assigned channel.

### 23.3.1.4 Monitoring pattern during multi-timeslot traffic operation

The BS may allocate a multi-slot traffic channel for circuit mode data calls. Monitoring pattern information shall be given by the BS along with the channel allocation at call set-up. A transmitting MS shall attempt to receive and decode downlink slots according to the assigned monitoring pattern(s). This allows the BS to send signalling, for example using the STCH, to a transmitting MS. The MS shall only be expected to adhere to the assigned monitoring pattern(s) within its duplex and switching capability. A BS should take this into account when attempting to transmit downlink signalling to a transmitting MS on a multi-slot channel. An MS transmitting on multiple slots per TDMA frame without a duplex or fast switching capability shall not be expected to receive signalling on the downlink in between transmitted bursts on the uplink; therefore the BS should only use frame 18 (or the lowest numbered slot in frame 1 - see note 1) for signalling to that MS during transmission.

NOTE 1: The MS will not always be able to receive the lowest numbered downlink slot in the frame 1's indicated by the assigned monitoring pattern(s) e.g. when the MS linearizes or transmits in the highest numbered uplink slot in frame 18.

The following requirements apply to reception in frames 1 to 17 by an MS with a duplex or fast switching capability:

- when an MS with frequency full duplex capability is transmitting in traffic mode on a multi-slot channel, it shall attempt to receive and decode all the downlink slots of the assigned channel, in those frames required by the monitoring pattern(s);
- when an MS with fast switching capability is transmitting in traffic mode on a multi-slot channel, it shall attempt to receive and decode any downlink slots of the assigned channel that it is capable of receiving, in those frames required by the monitoring pattern(s).

In frame 18, the MS shall attempt to receive and decode at least the highest numbered downlink slot of the assigned channel, in those frames required by the monitoring pattern(s) (see clause 23.3.1.3).

NOTE 2: Fast switching capability on a phase-modulated channel and frequency full duplex capability are indicated in the "class of MS" element (see clause 16).

## 23.3.2 Discontinuous transmission for CA

### 23.3.2.0 General

In the continuous mode of operation, the BS shall transmit continuously on the CA main carrier except during a BLCH. (If there is no signalling information to send, the BS may send broadcast PDUs or Null PDUs.) On the other carriers:

- for phase modulation carriers (i.e. carriers currently carrying  $\pi/4$ -DQPSK and/or D8PSK channel(s)), the BS may ramp down and up during slots on the unused physical channels; however, the inter-slot training sequence (i.e. normal training sequence 3) shall always be present and so this ramping down and up is transparent to the MS operation;
- for QAM carriers (i.e. carriers currently carrying QAM channel(s)), the BS shall transmit continuously except during a BLCH-Q.

The BS shall indicate continuous or discontinuous operation on phase modulation carriers by setting appropriately the "sharing mode" field broadcast in the SYNC PDU on the BSCH. Three modes of discontinuous transmission are defined:

- carrier sharing;
- MCCH sharing; and
- traffic carrier sharing.

These modes are described in the following clauses.

Discontinuous operation on a CA main carrier may be used for the purposes of sharing the channel resources between a number of cells. It may be desired to allocate different slots on the main carrier to different cells for  $\pi/4$ -DQPSK or D8PSK channels. This is known as carrier sharing operation. Alternatively, it may be desired to share slot 1 of the main carrier between a number of cells. This is known as MCCH sharing.

Discontinuous operation on phase modulation carriers other than the main carrier may be used for the purposes of sharing traffic resources between a number of cells for  $\pi/4$ -DQPSK and D8PSK channels. This may apply if the BS uses either mode of discontinuous operation on the main carrier. Otherwise it may apply only to the phase modulation carriers other than the main carrier. This is known as traffic carrier sharing.

**NOTE:** Irrespective of the value of the "sharing mode" field, the BS should transmit continuously on irregular phase modulation carriers (except during a BLCH), in order to allow MSs to perform irregular channel monitoring.

QAM carriers shall not be shared between cells using traffic carrier sharing, irrespective of the value of the "sharing mode" field: when the BS is using a carrier for QAM, it shall transmit continuously on that carrier (except during a BLCH-Q).

It is optional for the MS to implement the methods for operating with a BS that uses any of the discontinuous modes. The MS shall not attempt to obtain service from a BS that uses a discontinuous mode unless that MS is capable of performing the appropriate procedures.

### 23.3.2.1 Carrier sharing operation for CA

Carrier sharing operation allows the four slots of a CA main carrier to be shared between up to four adjacent cells. For example, each of four CA cells may be allocated one of the four timeslots on the main carrier, or each of two CA cells may be allocated two timeslots each. Interference is avoided by ensuring that only one of the cells sharing the carrier transmits on the downlink at any one time. This implies that the BSs sharing the main carrier need to be synchronized in time.

If the slot allocated to a BS is for use as a common control channel (i.e. MCCH or common SCCH), the BS shall transmit on the downlink in all frames for that slot (except during a BLCH). If the slot is for use as a traffic channel or assigned SCCH, the BS need not transmit on the downlink for that slot while it is not assigned. Indeed, a slot may be shared between a number of BSs for allocation as a traffic channel or as a  $\pi/4$ -DQPSK or D8PSK assigned SCCH.

The slot, frame and multiframe numbering may be independent between the cells sharing the main carrier. This means that all cells sharing a carrier can have a slot 1 for use as the MCCH for that cell.

Phase modulation carriers other than the main carrier may also be shared between adjacent cells for  $\pi/4$ -DQPSK and D8PSK channels. Therefore the MS designer should note that the BS may use discontinuous bursts on any of the phase modulation carriers of a carrier sharing cell.

### 23.3.2.2 MCCH sharing operation for CA

MCCH sharing allows a number of adjacent CA cells to share slot 1 of the main carrier for MCCH signalling. Up to 36 cells may share the same MCCH. Each cell has a number of reserved frames during which only the BS for that cell may transmit on the downlink MCCH. The remaining frames which are not reserved by any of the BSs sharing the MCCH may be used as common frames during which any of the BSs may transmit. However the network shall schedule downlink transmissions on common frames to ensure that two BSs do not transmit during the same common frame.

If the SYNC PDU indicates "MCCH sharing", the SYNC PDU shall also indicate the number of reserved frames for this BS using the "TS reserved frames" field. The "TS reserved frames" field shall indicate the number of frames reserved over two multiframe periods as defined in clause 9. The BS shall transmit on the downlink during these reserved frames.

During this mode of operation, the BSs shall also broadcast the location of the common frames by using the "TS\_COMMON\_FRAMES" field in the SYSINFO PDU sent on the BNCH. This field shall contain a bit map of the common frames for either the even-numbered or odd-numbered multiframes as indicated by the "Optional field flag".

In order for this mode of operation to work successfully, the transmission of downlink bursts shall be synchronized in time between the BSs sharing the MCCH. In addition, slot numbering shall be synchronized between the BSs to ensure that they all have a common view of when downlink slot 1 is transmitted. However, frame and multiframe numbering shall be offset in order to avoid collision of bursts transmitted during reserved downlink slots.

The remaining slots on the main carrier may be allocated as common SCCHs in which case the rules for reserved and common frames apply not only to slot 1 but also to those slots allocated as common SCCHs. Then the remaining slots not allocated for main or common secondary control may be shared between the BSs for use as traffic channels or as  $\pi/4$ -DQPSK or D8PSK assigned SCCHs. This sharing is performed on a carrier sharing basis; the rules for reserved and common frames do not apply to assigned channels. A BS need not transmit during these slots if they are not assigned.

On a shared MCCH or common SCCH, the MS shall attempt to receive and decode the relevant slot during reserved frames for this BS and during those frames marked as common. It shall use the colour code received in the SYNC PDU on choosing a cell on which to camp in order to de-scramble the PDUs. This ensures that the MS cannot decode those transmissions during common frames on adjacent cells. In addition, the MS shall only use SYNC PDUs which contain the correct value of the "colour code" element for this cell, since SYNC is not scrambled using the colour code meaning that an MS could receive SYNC from an adjacent cell; to prevent incorrect operation, only those with the correct value of the "colour code" element shall be interpreted by the MS.

Phase modulation carriers other than the main carrier may be shared between adjacent cells for  $\pi/4$ -DQPSK and D8PSK channels (on a carrier sharing basis). Therefore the MS designer should note that the BS may use discontinuous bursts on any of the phase modulation carriers of an MCCH sharing cell.

### 23.3.2.3 Traffic carrier sharing operation for CA

Traffic carrier sharing allows the four slots of phase modulation carriers other than the main carrier to be shared between adjacent cells for  $\pi/4$ -DQPSK and D8PSK channels. The BS shall transmit continuously on the main carrier (except during a BLCH). However, it may use discontinuous bursts on the other phase modulation carriers.

### 23.3.2a Discontinuous transmission for DA

For all QAM carriers (i.e. carriers currently carrying QAM channel(s)), the BS shall transmit continuously except during a BLCH-Q.

Therefore the equivalent of carrier sharing operation and MCCH sharing operation do not apply for DA cells.

However there are two possible modes of operation for any phase modulation carriers used by the BS:

- If phase modulation carrier sharing operation is used, this allows the four slots of phase modulation carriers to be shared between a number of adjacent cells for  $\pi/4$ -DQPSK and D8PSK channels. If the BS indicates that it may use phase modulation carrier sharing, the MS designer should note that the BS may use discontinuous bursts on phase modulation channels.
- If phase modulation carrier sharing operation is not used, the BS may still ramp down and up during slots on the unused physical channels on phase modulation carriers; however, the inter-slot training sequence (i.e. normal training sequence 3) shall always be present and so this ramping down and up is transparent to the MS operation.

In order for phase modulation carrier sharing operation to work successfully, the BSs sharing a phase modulation carrier need to be synchronized in slot timing (though the slot, frame and multiframe numbering may be independent between the cells).

The BS indicates whether it may use phase modulation carrier sharing by setting appropriately the one-bit "phase modulation carrier sharing mode" field broadcast in the SYSINFO-DA PDU.

QAM carriers shall not be shared between cells, irrespective of the value of the "phase modulation carrier sharing mode" field. When the BS is using a carrier for QAM, it shall transmit continuously on that carrier (except during a BLCH-Q).

NOTE: The BS should also transmit continuously on irregular phase modulation carriers (except during a BLCH), in order to allow MSs to perform irregular channel monitoring.

## 23.3.3 Minimum mode operation

### 23.3.3.0 General

Minimum mode operation allows a BS to allocate all four timeslots of a CA main carrier for traffic or assigned control purposes. Therefore, only frame 18 is available for common control. The following clauses describe the procedures for minimum mode operation which shall apply only to CA MSs that are in common control mode and receiving the MCCH. They do not apply to MSs on an assigned channel (traffic or assigned secondary control).

NOTE: Minimum mode is not supported for DA.

The BS should not allocate downlink slot 1 of a CA main carrier as a D8PSK channel. The BS should not allocate any timeslot of a CA main carrier as a QAM channel.

### 23.3.3.1 Beginning of minimum mode or no service mode

In the normal mode of operation, a CA MS shall receive the downlink of the MCCH and shall decode the AACH information (ACCESS-ASSIGN PDU). In the normal mode of operation, the MCCH is mapped to slot 1 of the main carrier frequency. The AACH in frames 1 to 17 shall indicate that downlink slot 1 is allocated for common control signalling, with the header set to  $00_2$  or "Field 1" set to  $UMc (000010_2)$ .

The BS may choose to enter minimum mode by allocating slot 1 of the main carrier for some other  $\pi/4$ -DQPSK purpose. The AACH shall indicate that downlink slot 1 is no longer allocated for common control.

If the AACH has header value =  $11_2$  and "field 1" =  $UMx (000000_2)$  and "field 2" =  $UMx (000000_2)$  then the BS is entering no service mode, and not entering minimum mode.

NOTE 1: Minimum mode is not supported for DA. However, no service mode may apply for DA; see clause 23.3.1.1.3 and clause 23.5.7.

All CA MSs in idle mode and currently receiving downlink slot 1 shall recognize when the system has entered minimum mode and should recognize when the system has entered no service mode.

Minimum mode during frame 18 shall be assumed by an MS if the AACH indicates that downlink slot 1 in frame 17 is allocated for some purpose other than common control signalling unless the AACH is indicating  $UMx$  for no service mode. If the AACH cannot be decoded in frame 17, then the MS shall assume that the BS is in the mode indicated by the last correctly decoded AACH in a downlink slot 1. The BS shall not enter minimum mode in frame 18 but may only indicate the beginning of minimum mode in the AACH of frames 1 to 17.

NOTE 2: In order to ensure robust operation, a BS may choose to enter minimum mode several frames before frame 18. This would ensure that all MSs have an increased probability of correctly decoding the AACH and taking the proper action during frame 18.

The BS shall not enter minimum mode while there is future capacity already granted for reserved access on the MCCH. Thus the BS shall wait until any granted slots or subslots on the MCCH have been used (or released by the Null PDU) before entering minimum mode.

### 23.3.3.2 MS operation during frames 1 to 17

During minimum mode, an MS shall receive slot 1 in frames 2 to 17 so that the BS may send signalling to an MS using the stealing channel or fast associated control channel. An MS shall decode the full contents of the slot to check whether the information is addressed to that MS. An MS shall decode the AACH in downlink slot 1 of frames 1 to 17 so that it can detect the end of minimum mode. If the end of minimum mode is detected, the MS shall also decode the full contents of that slot to check whether the signalling message contained is addressed to that MS (except if minimum mode ends in frame 1 in which case the BS should not assume that every MS is able to receive the full contents of the slot). An MS assigned to slot 1 during frame 18 in minimum mode shall decode the full contents of slot 1 in frame 1. All other MSs need only decode the AACH during slot 1 in frame 1.

The BS should not assume that every MS is able to decode slot 1 of frame 1 since an MS assigned to slot 4 in frame 18 may not be able to decode the following slot in frame 1.

### 23.3.3.3 MS operation during frame 18

During minimum mode, an MS shall receive one of the four downlink slots in frame 18 as allocated to that MS at registration or subscription. An MS is allocated a minimum mode frame 18 slot at registration or subscription and shall receive that assigned downlink slot in frame 18 if the BS has entered minimum mode. The BS, therefore, may sub-divide the MS population at registration between the frame 18 slots for minimum mode operation according to whatever criteria it chooses to apply, or the sub-division may be applied at subscription of the MS population. If an MS has been assigned a minimum mode slot at subscription and then also receives a minimum mode slot at registration, the one received at registration shall be used.

If the MS does not have a minimum mode slot on this network, and has no minimum mode slot from subscription, it shall use downlink slot 1 in frame 18 by default.

NOTE 1: Subscription is applicable only for the MS's home network.

NOTE 2: A BS may choose not to sub-divide the MS population in minimum mode, but instead may assign downlink slot 1 as the minimum mode frame 18 slot for all MSs.

Frame 18 slots shall be shared between idle MSs for common control channel signalling and MSs on assigned channels which use frame 18 for associated control signalling. The BS may send downlink signalling messages on a downlink slot intended either for an idle MS receiving that slot or for an MS on the assigned channel using that slot for associated signalling. The BS shall indicate the destination for signalling messages with an address in the MAC header.

NOTE 3: When an MS obeys a channel allocation command for an assigned channel, it may be permitted to continue to use the MCCH if it is capable of doing so (see clause 23.5.4). If the BS is in minimum mode, and if the assigned channel happens to correspond to the MS's minimum mode frame 18 slot, then there is a possible ambiguity of usage of the downlink slot in frame 18. If this occurs then the MS should not attempt concurrent random access on both the MCCH in minimum mode and the assigned channel. Also the BS should avoid sending ambiguous fragmented signalling in frame 18.

Frame 18 downlink slots shall also be used for broadcast control signalling. The normal mapping of frame 18 downlink slots for BNCH and BSCH as specified in clause 9 shall apply.

### 23.3.3.4 MS operation in energy economy or dual watch mode

During minimum mode, an MS in energy economy or dual watch mode shall not modify its reception behaviour. An MS waking up to find that the system is in minimum mode shall not modify its reception behaviour. The BS may page an MS in energy economy or dual watch mode even during minimum mode by using the STCH or FACCH in the MS's "awake" frames.

NOTE: If an MS in energy economy or dual watch mode on the MCCH perceives that the system is in minimum mode then, when it is required by clauses 23.7.6 or 23.7.7 to receive in frame 18, it receives and decodes slot 1. This applies even if the MS's nominal minimum mode frame 18 slot (as received at subscription or registration) is not slot 1.

### 23.3.3.5 End of minimum mode

During minimum mode, an MS shall continue to receive the AACH on downlink slot 1 of frames 1 to 17. If the AACH indicates that downlink slot 1 is allocated for common control purposes once again, the MS shall recognize that the BS is no longer in minimum mode and that normal mode operation has resumed.

The BS shall not leave minimum mode while there is minimum mode capacity already granted for reserved access in slot 2, 3 or 4 of frame 18. Thus the BS shall wait until any slots or subslots granted in slot 2, 3 or 4 of frame 18 for MSs in common control mode have been used before leaving minimum mode.

### 23.3.3.6 Restrictions on usage of minimum mode

The minimum mode procedures are not applicable for a BS that uses MCCH sharing.

The minimum mode procedures may apply for a BS that uses main carrier sharing. However, in this case, the MS shall always use downlink slot 1 in frame 18 as its minimum mode frame 18 slot, irrespective of any value received at subscription or registration.

The minimum mode procedures apply only to CA MSs that are in common control mode and receiving the MCCH. They do not apply to MSs on an assigned channel. Also, they do not apply to an MS that is receiving a common SCCH. If the AACH information indicates that the downlink slot is not being used for common control purposes, the MS should remain on its common SCCH unless the "number of common secondary control channels in use on CA main carrier" field changes in the SYSINFO PDU (BNCH).

The minimum mode procedures do not apply to MSs that are operating in DA mode.

It is optional for an MS to be capable of performing the minimum mode procedures. If the BS enters minimum mode, and the MS is not capable of performing the minimum mode procedures, then that MS will not receive service during minimum mode. The MS shall not attempt random access and need not decode slot 1 for signalling messages. A CA MS shall at least be able to recognize the beginning and end of minimum mode.

### 23.3.4 Independent allocation of uplink and downlink

A BS may allocate uplink and downlink channels for different purposes. This can apply to channels which are assigned for use as a traffic channel or control channel. For example, a traffic channel may be allocated in the downlink direction when there are only receiving mobiles for that cell and the corresponding uplink channel may be allocated for a call which only requires an uplink channel. The BS shall not allocate different modulation modes for the downlink channel and the corresponding uplink channel.

NOTE 1: The above requirement restricts the BS from allocating different modulation modes for the downlink channel and the corresponding uplink channel. Note, however, that the D8PSK modulation mode refers to a channel on which signalling and data messages may be sent using either  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK bursts. Therefore, on a D8PSK channel, both  $\pi/4$ -DQPSK and  $\pi/8$ -D8PSK bursts may be used on both uplink and downlink.

NOTE 2: In the present document, the only usage of D8PSK and QAM assigned channels is for assigned SCCH, so independent allocation of uplink and downlink applies only for  $\pi/4$ -DQPSK channels. However, in future editions of the present document, the BS may be permitted to allocate a D8PSK or QAM assigned SCCH in only one direction. Therefore the MS should expect that a D8PSK or QAM assigned SCCH may be allocated in only one direction.

Some examples are listed below:

- a) circuit mode call X on downlink channel;  
circuit mode call Y on uplink channel;
- b) circuit mode call on downlink channel;  
assigned SCCH on uplink channel;
- c) assigned SCCH on downlink channel;  
circuit mode call on uplink channel;
- d) common control on downlink MCCH (slot 1);  
uplink slot 1 of main carrier allocated for a circuit mode call;
- e) downlink slot 1 of main carrier allocated for a circuit mode call;  
uplink slot 1 of main carrier available for common control.

The allocation of uplink and downlink slots is indicated by the contents of the ACCESS-ASSIGN PDU, which is broadcast by the BS in every downlink slot on a  $\pi/4$ -DQPSK or D8PSK channel and may be broadcast in downlink slots on a QAM channel. All of the above examples can be accommodated with the available combinations of the header in the ACCESS-ASSIGN PDU (see clause 21 for more details). Also, when a channel is allocated, the "up/downlink assigned" or "up/downlink assigned for augmented channel allocation" element in the channel allocation shall inform the MS of any restrictions.

However, for the application of the general procedures for transmission and reception of signalling messages, each control channel (ACCH or SCCH) shall be assumed to occupy any control slots on both the uplink and downlink directions, as indicated by the "timeslot assigned" element in the channel allocation.

Therefore, for example, in case a), any ACCH in each direction shall be shared by the two unidirectional circuit mode calls. Similarly, in cases b) and c), the ACCH and SCCH shall be shared. In cases d) and e), the MSs in the circuit mode call shall share the common control channel.

NOTE 3: In case a), the two calls X and Y generally involve different MSs. However, it is possible that they may be concurrent calls involving the same MS.

### 23.3.5 Usage of a multi-slot channel

A "channel" or "MAC channel", as used in the MAC protocol, means a common control channel or assigned channel.

- For CA, a common control channel comprises one timeslot per TDMA frame on a pair of radio carrier frequencies (downlink and uplink) so it equates with a physical channel; see clause 9.4.1.
- For DA, the MCCH-Q may comprise more than one timeslot per TDMA frame on a pair of radio carrier frequencies. It then corresponds to a combination of up to four physical channels. Any common SCCHs comprise one timeslot per TDMA frame on the pair of radio carrier frequencies.
- An assigned channel may comprise more than one timeslot per TDMA frame on a pair of radio carrier frequencies. It then corresponds to a combination of up to four physical channels, as indicated by the "timeslot assigned" element in the MAC-RESOURCE or MAC-END PDU that sent the MS to the channel.

NOTE 1: A common control channel is a  $\pi/4$ -DQPSK channel for CA or a QAM channel for DA. An assigned channel (either single-slot or multi-slot) may be a  $\pi/4$ -DQPSK, D8PSK or QAM channel.

For the purposes of the procedures for transmission and reception of signalling messages on an assigned SCCH or an ACCH or the MCCH-Q, all the slots comprising a multi-slot channel are equivalent. Downlink signalling messages (including continuation fragments and final fragments) may be sent on any downlink slot appropriate to that channel. Also, when the MS is counting slots on the channel (e.g. for the granting delay or for a reserved access allocation), all the slots appropriate to that channel shall be counted continuously.

This contrasts with the method for a multi-slot circuit mode data service with interleaving depth  $N = 4$  or  $8$ . In this case, when the assigned channel is in traffic mode, multiple single-slot data TCHs (TCH/2,4 or TCH/4,8) shall be operated in parallel in order to obtain the multi-slot TCH transmission. The  $N$ -slot interleaving shall be performed within each single-slot TCH, such that interleaved blocks are separated by three timeslots.

NOTE 2: The use of multiple single-slot data TCHs for the interleaving ensures that the performance of multi-slot circuit mode data is the same as that for single-slot circuit mode data with the same interleaving depth. This method applies only when the assigned channel is in traffic mode. When the channel is not being used for TCH, the channel reverts to FACCH and the normal signalling methods apply.

### 23.3.6 Usage of a 50 kHz, 100 kHz or 150 kHz channel

In the case of a  $\pi/4$ -DQPSK or D8PSK channel, the bandwidth of the channel is 25 kHz.

In the case of a QAM channel, the bandwidth of the channel is 25 kHz, 50 kHz, 100 kHz or 150 kHz:

- for both CA and DA, the bandwidth of a QAM assigned channel is indicated by the "channel allocation" element in the MAC-RESOURCE or MAC-END PDU;
- for DA, the bandwidth of the DA main carrier is indicated by the "DA main carrier bandwidth" element in the SYNC-DA and SYSINFO-DA PDUs.

For a wide-bandwidth channel, the SCH MAC blocks are larger than for a narrower channel. Apart from the SCH MAC blocks being larger: for the purposes of the transmission and reception of signalling messages, the bandwidth does not generally affect the MAC procedures with the following exceptions:

- Random access messages are always sent using a 25 kHz bandwidth. (When an MS has chosen a subslot in an access frame and counted subslots to its chosen subslot in time using the same procedures as for a 25 kHz channel, it then makes a further random choice of which 25 kHz frequency block to use within the wider bandwidth; see clause 23.5.1.)

- The normal advanced link data segment size depends on the bandwidth of the channel. (The MS-MAC informs the LLC of the normal advanced link data segment size when it issues the MAC-READY signal.)

A wide-bandwidth channel may comprise more than one timeslot per TDMA frame, in which case clause 23.3.5 also applies.

## 23.4 General MAC procedures

### 23.4.1 PDU header analysis for signalling messages

#### 23.4.1.1 MAC PDU types

The header of each MAC PDU enables the receiving MAC to interpret its contents correctly (see clause 21 for a full description of the PDUs).

#### 23.4.1.2 Addressing at the TMA-SAP

##### 23.4.1.2.0 General

The TMA-SAP MAC headers generally contain an "Address" element and an element specifying the type of address. This layer 2 address is the source address for an uplink PDU, or the destination address for a downlink PDU.

Another address (when needed) may be contained within the layer 3 part of the message e.g. the called address for an uplink PDU, or the calling address for a downlink PDU. The infrastructure makes the required address conversion between the uplink and downlink PDUs as appropriate.

The usage of TETRA addresses and identities is described in ETSI EN 300 392-1 [6], clause 7.

The address in the MAC header shall be a Short Subscriber Identity (SSI/USSI), a Short Management Identity (SMI) or an event label. An SSI/USSI is a 24-bit address specific to a particular TETRA network and is part of the complete TETRA Subscriber Identity (TSI). The 24-bit SMI is part of the TETRA Management Identity (TMI). An event label is a 10-bit MAC address that may be used to replace an SSI or SMI.

The MS procedures throughout clause 23 apply to the requirements for a single TSI family. If an MS contains more than one TSI family (see ETSI EN 300 392-1 [6], clause 7), then each family shall meet the MAC protocol requirements independently of other families.

##### 23.4.1.2.1 Downlink message

When the BS transmits a downlink MAC-RESOURCE PDU, it shall use one of the following addresses as appropriate as the destination address:

- an Individual Short Subscriber Identity (ISSI);
- an Alias Short Subscriber Identity (ASSI);
- an Un-exchanged Short Subscriber Identity (USSI), used only until a migrating MS has been assigned a valid address on this network;
- a Group Short Subscriber Identity (GSSI);
- a Short Management Identity (SMI);
- a valid event label (see clause 23.4.1.2.3).

The "address type" element in the MAC header shall indicate whether the address is an SSI (ISSI/ASSI/GSSI), event label, USSI or SMI; and may be used to assign an event label (or a usage marker).

When the BS transmits a MAC-D-BLCK PDU, it shall use a valid event label as the destination address.

The receiving MS-MAC shall use the contents of a MAC-RESOURCE or MAC-D-BLCK PDU only if it recognizes the address as one of its own valid addresses or event labels. The one exception is that the MS-MAC shall process the MAC header in all received PDUs sufficiently to deduce the length of the PDU, in order to perform dissociation of multiple PDUs sent within a MAC block.

If the MS-MAC receives a PDU with one of its valid addresses or event labels, it shall pass the TM-SDU to the LLC using the TMA-UNITDATA indication primitive. It shall indicate the received address and address type, unless the received address is an event label in which case the MS-MAC shall translate the event label into the corresponding SSI or SMI before passing the information to the LLC.

NOTE 1: The other downlink TMA-SAP PDUs are used for continuations and end of a fragmented TM-SDU, and do not contain addressing information.

NOTE 2: There is no distinction between an ISSI, ASSI or GSSI in the PDU. There is no distinction between an ISSI and an ASSI in the MAC. However, it is assumed that the MS-MAC knows which of its addresses are group addresses. The MS-MAC also knows which of its addresses is the SMI, and it knows whether an address is an USSI.

NOTE 3: The predefined broadcast group address ("all ones" address), as described in ETSI EN 300 392-1 [6], clause 7, defines a group to which all MS belong. For example, it may be used as the destination address for CMCE or packet data calls, or it may be used by the BS for sending broadcast signalling messages using the services provided at the TLA-SAP and TMA-SAP.

NOTE 4: After an ASSI has been allocated to the MS, the ISSI remains available and may still be used by the BS if required. The MS therefore continues to recognize its ISSI on the downlink. This applies only on a home network, and not in the case of migration when the MS does not have a valid ISSI for the network.

#### 23.4.1.2.2 Uplink message

When the MS-MAC is required to send a C-plane message, it receives a TMA-UNITDATA request primitive from the LLC. This primitive shall contain the appropriate layer 2 address (the main address) and the address type.

The main address in the request primitive shall be one of the following:

- the MS's ISSI or ASSI for the network;
- an USSI, used only by a migrating MS for the initial registration request;
- a GSSI;
- the SMI for the MS.

When the MS-MAC forms a MAC-ACCESS or MAC-DATA PDU, it shall use the main address from the TMA-UNITDATA request primitive in the PDU "Address" element, unless an event label has been assigned for this address (see clause 23.4.1.2.3) in which case it may use the event label when appropriate. The "Address type" element in the MAC header shall indicate whether the "Address" element contains an SSI (ISSI/ASSI/GSSI), event label, USSI or SMI.

If an event label has been assigned for the main address, and fragmentation is not needed, the MS-MAC may optionally use a MAC-U-BLCK PDU instead of a MAC-DATA PDU - if the pre-defined length is appropriate (see clause 21.4.2.6) and the BS supports the MAC-U-BLCK PDU.

NOTE 1: The other uplink TMA-SAP PDUs are used for continuations and end of a fragmented TM-SDU, and do not contain addressing information.

NOTE 2: A group address in the MAC header is used on the uplink for the low level group presence indication (see clauses 22.2.1.3 and 22.3.1.2). This is the only case for which a group address is used in the MAC header on the uplink.

NOTE 3: After an ASSI has been allocated to the MS, and while it is still valid, that ASSI should be used in uplink messages in preference to the ISSI.

### 23.4.1.2.3 Event labels

#### 23.4.1.2.3.0 General

An "event label" is a temporary shortened form of address which replaces a specified SSI (ISSI, ASSI or GSSI) or a specified SMI in the MAC PDUs, and is visible only at the MAC layer. It is valid only on one MAC channel. Its usage is illustrated in figure 23.6.

Event label 000000000<sub>2</sub> (all zeros) may be used by the BS for withdrawing an event label assignment (using "address type" 101<sub>2</sub> or 111<sub>2</sub>). It is not valid for normal use.

Event label 111111111<sub>2</sub> (all ones) may be used by the BS (with "address type" 101<sub>2</sub> or 111<sub>2</sub>) to indicate that current event labels remain valid after a channel change. It is not valid for normal use.

#### 23.4.1.2.3.1 General usage of event labels

When the BS wishes to assign an event label, it shall use the MAC-RESOURCE PDU, which shall contain both the SSI (or SMI) and the assigned event label.

- a) If the BS includes an event label assignment in a MAC-RESOURCE PDU containing a non-fragmented message then:
  - if the BS includes a "channel allocation" element in the MAC-RESOURCE PDU then the event label shall apply on the allocated channel (see note 1);
  - otherwise the event label shall apply on the current channel.
- b) If the BS includes an event label assignment in the MAC-RESOURCE PDU of a fragmented message then the event label shall not apply until the associated MAC-END PDU has been received. Then:
  - if the BS includes a "channel allocation" element in the MAC-END PDU then the event label shall apply on the allocated channel (see note 1);
  - otherwise the event label shall apply on the current channel.

If the MS discards the partially reconstructed TM-SDU (as described in clause 23.4.3.1.1) then it shall ignore the event label assignment.

NOTE 1: If the MS does not obey the channel allocation, it ignores the event label assignment.

NOTE 2: For a channel allocation with "allocation type" = 11<sub>2</sub> (Replace + CSS channel), the event label applies only on the assigned channel, not on the CSS channel. (See clause 23.5.4 for a description of the allocation types.)

The MS-MAC may then use the event label (if neither all zeros nor all ones) instead of the corresponding SSI (respectively SMI) as the source address in uplink PDUs sent on this channel; see figure 23.6. While the event label is valid, it may be used for both basic link and advanced link messages, and for random access, reserved access and STCH.

NOTE 3: Thus, while the event label is valid, it may replace the SSI or SMI in any uplink PDUs sent on this channel. As defined in clause 23.3.5, all the slots comprising a multi-slot channel (i.e. a multi-slot assigned channel or multi-slot MCCH-Q) are equivalent for the purposes of the general signalling procedures. Therefore an assigned event label applies to all slots of a multi-slot channel.

The BS may use the event label as the destination address in downlink PDUs (though the corresponding SSI or SMI may still be used). If the MS-MAC receives a downlink PDU containing a valid event label then it shall process the information contained in that PDU. The MS-MAC shall translate the event label into the corresponding SSI (respectively SMI) before passing the TM-SDU to the LLC.

The event label has a limited lifetime. The MS-MAC shall consider that an assigned event label is no longer valid in the following cases:

- 1) A time T.201 has elapsed since the MS last received a downlink PDU containing that event label. Then the MS-MAC shall revert to using the SSI (respectively SMI).

- 2) The MS receives another event label assignment (other than event label 11111111<sub>2</sub>) on this channel, for the same SSI (respectively SMI). Then, if the received event label is non-zero, the MS-MAC shall accept that new event label; if the received event label = 0, the MS-MAC shall revert to using the SSI (respectively SMI).
- 3) The MS moves to another channel (unless the MS is leaving the channel as a result of a channel allocation message sent with "address type" 101<sub>2</sub> or 111<sub>2</sub> and containing event label 11111111<sub>2</sub>). Then the MS-MAC shall revert to using the SSI (respectively SMI), unless a new event label was assigned with the channel allocation.

NOTE 4: In case 3), the MS discards an event label if it leaves the physical resource for which the event label was assigned i.e. the timeslot or timeslots on the appropriate carrier on this cell. The MS also discards an event label if the width of the channel (i.e. the number of timeslots allocated for the channel) is increased or decreased. As defined in clause 23.4.1.2.3.3, an exception to this definition occurs if the MS obeys a channel allocation command sent with "address type" 101<sub>2</sub> or 111<sub>2</sub> and containing event label 11111111<sub>2</sub>.

An event label is retained if a single-slot channel changes from common to assigned or from assigned to common.

An event label is retained if a DA MS changes from common mode to assigned mode, or from assigned mode to common mode, on the same timeslot of the DA main carrier - or on the same timeslots of the DA main carrier for multi-slot MCCH-Q.

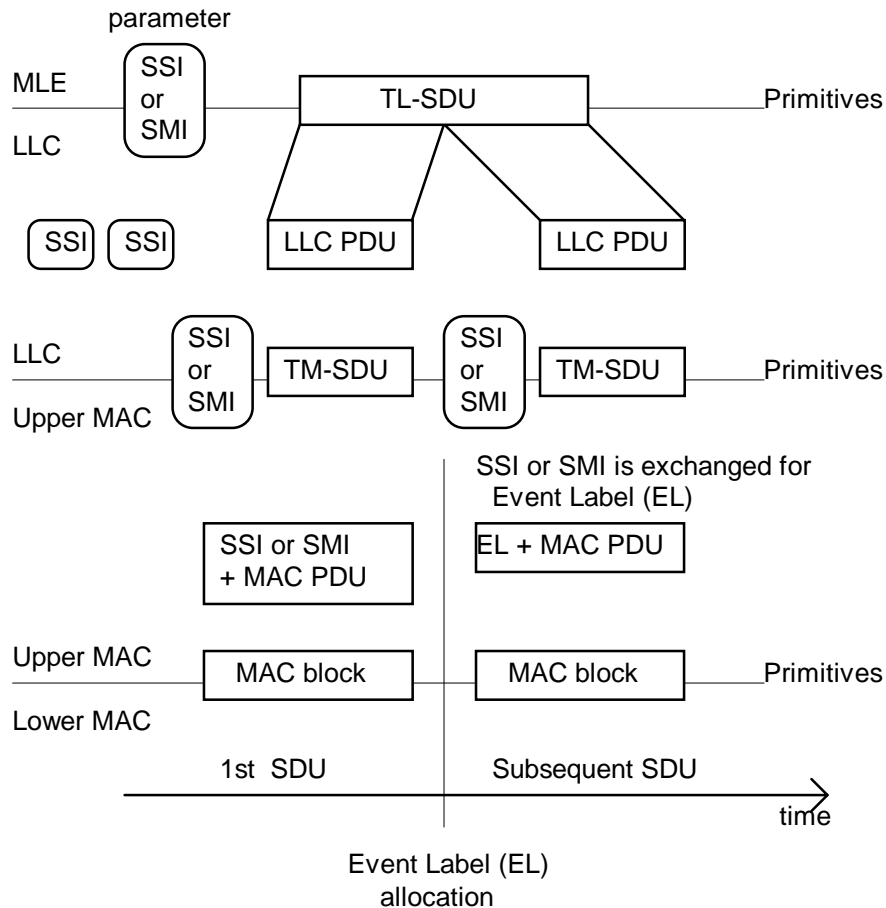

If the BS changes the number of common SCCHs then an event label is retained if the MS continues to use the same timeslot on the main carrier, but is discarded if the MS moves to a different timeslot.

An event label is retained when the BS enters and leaves minimum mode even if the MS's minimum mode frame 18 slot is not slot 1.

The BS is responsible for ensuring that it does not re-use an event label for another MS until the valid lifetime has expired.

If the BS establishes or accepts an advanced link for the acknowledged service to carry TL-SDUs with a maximum length of 4 096 octets then, in the case of a 25 kHz QAM channel, the BS shall assign an event label for that MS address for use on that channel. Similarly, if the BS establishes an advanced link for the unacknowledged service to carry TL-SDUs with a maximum length of 4 096 octets then, in the case of a 25 kHz QAM channel, the BS shall assign an event label for that address for use on that channel.

NOTE 5: Event label assignment is intended primarily for when an advanced link (or advanced links) have been set up for the appropriate address. However, its use is not precluded when there is only a basic link.

**Figure 23.6: V+D air interface addressing**

#### 23.4.1.2.3.2 Usage of event label all zeros

As defined above, the BS may use event label 0 to withdraw an event label assignment (using "address type"  $101_2$  or  $111_2$  i.e. SSI/SMI + Event Label). Event label 0 is not valid for use at other times. Thus it is not valid for use in downlink PDUs with "address type"  $010_2$  or in uplink PDUs with "address type"  $01_2$ , or in MAC-D-BLCK or MAC-U-BLCK PDUs. If an MS receives a MAC-RESOURCE PDU with "address type"  $010_2$  and event label = 0, or a MAC-D-BLCK PDU with event label = 0, it shall ignore the PDU; or, if the BS receives a MAC-ACCESS or MAC-DATA PDU with "address type"  $01_2$  and event label = 0, or a MAC-U-BLCK PDU with event label = 0, it shall ignore the PDU.

#### 23.4.1.2.3.3 Usage of event label all ones

When the BS sends a channel allocation, it may use "address type"  $101_2$  or  $111_2$  (i.e. SSI/SMI + Event Label) with the event label set to  $11111111_2$  to indicate to those MS or MSs addressed by the SSI or SMI that their event labels from the current channel shall be valid on the allocated channel. For an MS addressed by the SSI/SMI, this indicates that all its event labels (for all its addresses) from the current channel shall be valid on the allocated channel - not only the event label corresponding to the SSI/SMI.

NOTE 1: For a channel allocation with "allocation type" =  $01_2$  (Add), the event labels from the current channel are then valid on both the current channel and the allocated channel.

For a channel allocation with "allocation type" =  $11_2$  (Replace + CSS channel), the retention of event labels from the current channel applies only on the assigned channel, not on the CSS channel.

NOTE 2: As an example: the BS could use "address type"  $101_2$  or  $111_2$  with event label  $111111111_2$  if it wishes to replace an assigned channel ("allocation type" =  $00_2$ ) without invalidating the current event labels. This could apply if the BS wishes to change the width of the assigned channel (e.g. for a packet data channel PDCH) or if it wishes to replace the channel for any other reason. If the BS chooses to use the predefined broadcast group address (all ones SSI) then the replacement would apply to all the MSs on the current channel and would allow all the event labels from the current channel to remain valid on the new channel.

If the BS uses "address type"  $101_2$  or  $111_2$  with event label  $111111111_2$  in a MAC-RESOURCE PDU containing a non-fragmented message then the event labels from the current channel shall apply on the channel allocated by the "channel allocation" element in the MAC-RESOURCE PDU. If the BS uses "address type"  $101_2$  or  $111_2$  with event label  $111111111_2$  in a MAC-RESOURCE PDU containing a fragmented message then the event labels from the current channel shall apply on the channel allocated by the "channel allocation" element in the associated MAC-END PDU.

If the MS either:

- does not have any event labels on the current channel; or
- does not obey the channel allocation;

then it shall ignore the event label part of the MAC-RESOURCE PDU - obeying the other procedures within clause 23 as if the PDU had been sent with "address type"  $001_2$  or  $100_2$ .

Event label  $111111111_2$  is not valid for use at other times. Thus it is not valid for use in downlink PDUs unless there is an associated channel allocation. If an MS receives a MAC-RESOURCE PDU with "address type"  $101_2$  or  $111_2$  and event label  $111111111_2$  without receiving an associated channel allocation, it shall ignore the event label part of the PDU (obeying other procedures within clause 23 as if the PDU had been sent with "address type"  $001_2$  or  $100_2$ ). Also event label  $111111111_2$  is not valid for use in downlink PDUs with "address type"  $010_2$  or in uplink PDUs with "address type"  $01_2$ , or in MAC-D-BLCK or MAC-U-BLCK PDUs. If an MS receives a MAC-RESOURCE PDU with "address type"  $010_2$  and event label =  $111111111_2$ , or a MAC-D-BLCK PDU with event label =  $111111111_2$ , it shall ignore the PDU; or, if the BS receives a MAC-ACCESS or MAC-DATA PDU with "address type"  $01_2$  and event label =  $111111111_2$ , or a MAC-U-BLCK PDU with event label =  $111111111_2$ , it shall ignore the PDU.

#### 23.4.1.2.4 Usage of SMI

The SMI is an address specific to a particular TETRA network and is part of the complete TMI. The management identity can be used to address a particular piece of equipment independently from the subscriber identity.

NOTE: The subscriber identities may be transferable, and may be removed from the equipment by the user.

The SMI enables management functions to be performed over the air interface. Alternatively, if the infrastructure knows the correspondence between the equipment and the SSI, it may use the SSI for the management functions, since the management messages can be recognized by the MLE (see clause 18).

The SMI may be numerically equal to an SSI attached either to that MS or to another MS. The SSI and SMI remain distinct because they can be distinguished by the address type in the MAC PDUs.

#### 23.4.1.2.5 Usage of USSI

An USSI is the SSI of an MS from a foreign ITSI. It shall only be used in case of migration, when the MS does not have a valid ISSI or ASSI for the network, and shall only be used for the registration procedure. The USSI shall be equal to the ISSI used by the MS in its home network.

When migrating into a network, the first message sent by an MS shall be a registration request, with the USSI as the layer 2 source address. The home MCC and MNC are included within the layer 3 part of the message.

The USSI is then used on the downlink, in the BS response, as the layer 2 destination address. Also, if the layer 3 reply from the BS is not sent with the MAC response, the USSI will be used again as the layer 2 address when the BS sends the layer 3 reply.

The layer 3 reply to the registration request carries an ASSI for the visiting MS; that new SSI shall then be used by the MS inside the visited network. The allocated ASSI may be (by chance) equal to the USSI, but usually is not.

Sometimes, the USSI may be numerically equal to an SSI or SMI already in use by another MS on the visited network. The signalling messages remain distinct because they can be distinguished by the address type in the MAC PDUs.

Sometimes, the USSI may be numerically equal to the USSI of another migrating MS that is trying to register at the same time. In this case, the downlink signalling messages are not distinct at layer 2. However, the layer 3 reply from the BS contains the MS's home MCC and MNC, and the MM in the MS will discard a received reply if it has incorrect MCC or MNC (see clause 16).

As stated above, there are cases when downlink signalling messages containing the USSI are not distinct at layer 2, so reserved capacity granted before the BS sends a layer 3 reply could occasionally be accepted by more than one migrating MS. Thus, if a migrating MS's first registration request exceeds the capacity of the random access message and the MS uses fragmentation, there is a possibility that the BS might reconstruct a TM-SDU from fragments sent by two different migrating MSs. Therefore, if a migrating MS's first registration request exceeds the capacity of the random access message, the MS shall either:

- a) include the optional FCS when sending the first registration request (in which case it may use fragmentation); or
- b) choose not to include a first fragment of TM-SDU in the random access message - instead just requesting reserved capacity in the random access message and then sending the TM-SDU without fragmentation in the granted slot or subslot.

NOTE: In the case of migration to a CA cell, the MS's first registration request normally fits within the random access message. However, in the case of migration to a DA cell, the MS's first registration request does not fit within the random access message, so the MS needs to use method a) or b) above.

After the MS has received an ASSI, and has sent the LLC response if appropriate, usage of the USSI becomes invalid on this network for as long as the MS has a valid ASSI (see clause 16.4.7); the MS shall not use the USSI in uplink messages and shall not recognize the USSI in downlink messages.

### 23.4.1.3 Addressing at the TMB-SAP

The characteristic of this SAP is that the broadcast information (system information) is implicitly addressed to every MS and, in order to keep the overhead as low as possible, does not contain an address field. The MAC PDU type under the TMB-SAP is distinct from those used under the TMA-SAP (see clause 21). The LLC shall be transparent for system broadcasts. No address is reported by the MAC to the MLE.

NOTE: Broadcast messages under the TMB-SAP comprise only the SYNC PDU (contained in the BSCH), SYSINFO PDU (contained in the BNCH), SYSINFO-Q PDU (contained in the BNCH-Q), SYNC-DA PDU (contained in the BSCH-Q), SYSINFO-DA PDU (generally contained in the BNCH-Q) and ACCESS-DEFINE PDU. They should not be confused with signalling messages addressed to a group of MSs in the downlink using a specific group address at the TLA-SAP and TMA-SAP. Broadcast to all MSs in a cell or wider area may use the predefined broadcast group address ("all ones" address) and the services provided at the TLA-SAP and TMA-SAP (see clause 23.4.1.2.1).

### 23.4.1.4 Addressing at the TMD-SAP

There is no addressing at the TMD-SAP. There may be multiple endpoints in the TMD-SAP which shall be associated with the corresponding CC instance and address used in the set-up phase in the user application.

If the MAC steals from the circuit mode capacity to send C-plane signalling, it shall use TMA-SAP PDUs and addressing.

## 23.4.2 PDU composition for signalling messages

### 23.4.2.0 General

This clause describes the mechanisms whereby PDUs may be transmitted in the SCH MAC blocks. Three general mechanisms are provided:

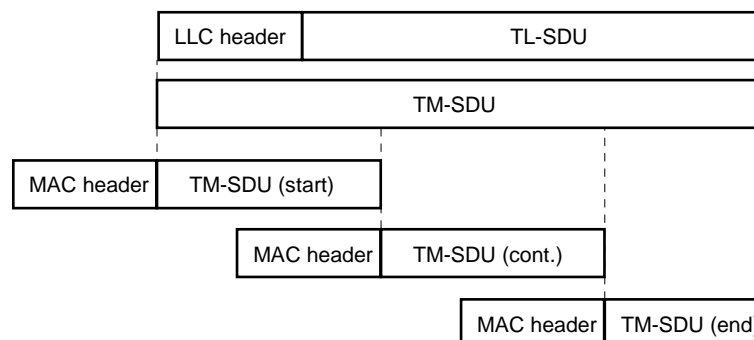

- a) Fragmentation:
  - This is the subdivision procedure that shall be used by an MS-MAC or BS in the case that a TM-SDU received from the LLC exceeds the available capacity in a MAC block. The transmission of the TM-SDU is then subdivided between two or more MAC blocks.
- b) Fill bit addition:
  - The length of a MAC PDU is generally represented as a number of octets. In other cases the MAC PDU has an implicit length. "Fill bits" shall be used when the PDU does not fully occupy the indicated or implicit PDU length. They are used to make up the difference between the actual PDU content and the indicated or implicit length, and they also show the exact end of the TM-SDU.
- c) Association:
  - This is the procedure that may be used by an MS or BS for sending two or more PDUs within a single MAC block.

The reverse procedures (called reconstruction, fill bit deletion and dissociation respectively) are described in clause 23.4.3.

### 23.4.2.1 Fragmentation (TMA-SAP only)

#### 23.4.2.1.0 General

Fragmentation is the procedure that shall be used by an MS-MAC or BS in the case that a TM-SDU received from the LLC exceeds the available capacity in the MAC block. The MAC subdivides the TM-SDU into a number of fragments, where each fragment is sent within one MAC PDU. The whole TM-SDU contains only a single LLC header. This procedure is illustrated in figure 23.7. Fragments are not numbered, and so they shall be sent in sequence. If an error occurs during transmission then the MAC procedure fails (and the LLC has to request a re-transmission of the whole TM-SDU). From the point of view of the higher layers, the process is the same as if the TM-SDU had been transmitted in a single MAC block.

**Figure 23.7: MAC fragmentation of a long TM-SDU**

The first fragment of a TM-SDU shall be sent with a full MAC header (MAC-RESOURCE PDU on the downlink, MAC-ACCESS or MAC-DATA PDU on the uplink). Whereas continuation fragments (MAC-FRAG PDU) and the final fragment (MAC-END or MAC-END-HU PDU) shall be sent with a reduced MAC header (see clause 21). In particular, only the full MAC header contains addressing information.

Fragmentation applies only to subdivision of the actual TM-SDU. The MAC header cannot be subdivided between MAC blocks.

On the downlink, the BS may temporarily interrupt a fragmented message to send other signalling whereas, on the uplink, the MS-MAC shall not interleave any other signalling with a fragmented TM-SDU.

NOTE 1: The fragmentation procedure is intended primarily for use for basic link messages, if a TM-SDU exceeds the capacity of the MAC block. It is recommended that the MS/BS does not normally fragment advanced link messages. However fragmentation is needed on a D8PSK channel when an advanced link segment first sent using  $\pi/8$ -D8PSK modulation is re-transmitted using  $\pi/4$ -DQPSK modulation. Fragmentation may also be needed for re-transmissions of advanced link segments after a reduction of bandwidth (for example, if the bandwidth of a QAM channel changes from 150 kHz to 50 kHz).

NOTE 2: The fragmentation procedure is not intended for very long messages:

- a) It is recommended that fragmentation is not used for TL-SDUs that cannot be carried within a MAC-ACCESS PDU + four full slots.

The capacity of MAC blocks depends on the modulation, and also the bandwidth and coding rate for QAM. The longest recommended size of TM-SDU and TL-SDU for use of fragmentation is shown in table 23.7 (in which it is assumed that the MAC-ACCESS PDU is sent by random access using an SSI and the full slots are sent using the indicated transmission method). For example, on a  $\pi/4$ -DQPSK channel, it is recommended that fragmentation is not used for TM-SDUs exceeding 1 106 bits; this corresponds to a TL-SDU of approximately 133 octets (if using FCS) or 137 octets (if not using FCS).

- b) The maximum permitted TM-SDU size is 2 632 bits (N.202), so fragmentation cannot be used for TL-SDUs exceeding approximately 324 octets (if using FCS) or 328 octets (if not using FCS).

Instead, the MLE should set up an advanced link (or use an existing advanced link).

It is recommended that the MLE uses the optional FCS if it sends long messages on the basic link (particularly if fragmentation is needed), but not when it sends short signalling messages.

NOTE 3: There is no MAC acknowledgement or MAC re-transmission of a fragmented TM-SDU. Acknowledgements and retransmissions are under the control of the LLC.

**Table 23.7: Longest recommended size of TM-SDU / TL-SDU for fragmentation**

| Modulation and QAM coding rate and bandwidth for reserved access | Longest recommended size of TM-SDU for fragmentation [bits] | Approximate longest recommended size of TL-SDU for fragmentation [octets] if using FCS | Approximate longest recommended size of TL-SDU for fragmentation [octets] if not using FCS |
|--|---|--|--|
| $\pi/4$ -DQPSK   | 1 106   | 133  | 137  |
| $\pi/8$ -D8PSK   | 1 682   | 205  | 209  |
| 4-QAM rate=1/2, 25 kHz   | 731   | 86   | 90   |
| 16-QAM rate=1/2, 25 kHz  | 1 531   | 186  | 190  |
| 16-QAM rate=1, 25 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 64-QAM rate=1/2, 25 kHz  | 2 331   | 286  | 290  |
| 64-QAM rate=2/3, 25 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 64-QAM rate=1, 25 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 4-QAM rate=1/2, 50 kHz   | 1 563   | 190  | 194  |
| 16-QAM rate=1/2, 50 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 16-QAM rate=1, 50 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 64-QAM rate=1/2, 50 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 64-QAM rate=2/3, 50 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| 64-QAM rate=1, 50 kHz  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| QAM, 100 kHz<br>(any modulation level and rate)                  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |
| QAM, 150 kHz<br>(any modulation level and rate)                  | 2 632 (see note)  | 324 (see note)   | 328 (see note)   |

NOTE: This corresponds to the maximum permitted size of TM-SDU (N.202).

### 23.4.2.1.1 Fragmentation of downlink TM-SDU

When the BS wishes to send a TM-SDU that does not require fragmentation, it shall send the entire TM-SDU within the MAC-RESOURCE PDU, or within the MAC-D-BLCK PDU (if the pre-defined length is appropriate and the MAC-D-BLCK PDU is supported by the addressed MS(s); see "class of MS" element in clause 16).

NOTE 1: A single bit in the "class of MS" element indicates whether the MS supports reception of the MAC-D-BLCK PDU and augmented channel allocations. MSs that support D8PSK and/or QAM operation need to support augmented channel allocations in order to be allocated to a D8PSK or QAM channel; they therefore need to support reception of the MAC-D-BLCK PDU. It is optional whether an MS that only supports  $\pi/4$ -DQPSK operation supports reception of the MAC-D-BLCK PDU and augmented channel allocations.

When the BS wishes to send a TM-SDU that exceeds the available capacity within a MAC block, it may subdivide the TM-SDU into fragments, which shall be sent on this control channel, in the following sequence:

- a) the first fragment shall be sent using the MAC-RESOURCE PDU;
- b) any continuation fragments shall be sent using  $n \times$  MAC-FRAG PDUs (where  $n \geq 0$ );
- c) the final fragment shall be sent using the MAC-END PDU.

Since the MAC-END PDU header is longer than the MAC-FRAG PDU header, there may be some cases when the remainder of the TM-SDU fits within MAC-FRAG but would not fit within MAC-END. In these cases, the BS should send the remaining data within MAC-FRAG (with fill bits if necessary) and then send an empty MAC-END PDU to complete the message.

When the BS has sent one or more fragments of a fragmented message, it may temporarily interrupt the transmission if necessary to send a TMB-SAP broadcast message or a non-fragmented TMA-SAP message (but not a fragmented message). However the following points may be noted:

- The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every  $N \cdot 203^{\text{th}}$  slot on this downlink control channel; see reconstruction by MS given in clause 23.4.3.1.1.
- The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it fails to decode an SCH MAC block on this control channel; see reconstruction by MS given in clause 23.4.3.1.1. Therefore, on a D8PSK channel, if the BS interrupts the transmission of a  $\pi/4$ -DQPSK fragmented message to send a non-fragmented message using  $\pi/8$ -D8PSK modulation, this may cause the reconstruction of the fragmented message to fail (i.e. if the MS cannot currently receive SCH at the higher bit rate). Similarly, on a QAM channel, if the BS interrupts the transmission of a fragmented message to send a non-fragmented message using a higher modulation level and/or less coding, this may cause the reconstruction of the fragmented message to fail (i.e. if the MS cannot currently receive SCH at the higher bit rate).
- The MS-MAC receiving a fragmented message on a QAM channel will discard a partially received TM-SDU if it does not understand the value of the "slot format" element in the downlink QAM-SLOTINFO PDU in a slot on this downlink control channel; see reconstruction by MS given in clause 23.4.3.1.1. Some CA MSs may not understand the value of the "slot format" element that indicates a QAM FCB. Therefore, if the BS interrupts the transmission of a fragmented message to a CA MS to send a SYNC-DA PDU (in either a predefined or non-predefined position), this may cause the reconstruction of the fragmented message to fail.

NOTE 2: Similarly, some CA MSs may not understand the SYSINFO-DA PDU and therefore will not know the length of the SYSINFO-DA PDU - so cannot process associated PDUs following the SYSINFO-DA PDU in a downlink MAC block. Also such MSs may decide to discard a partially received TM-SDU if the BS sends a SYSINFO-DA PDU. Thus, if the BS interrupts the transmission of a fragmented message to a CA MS to send a SYSINFO-DA PDU (in either a predefined or non-predefined position), this may cause the reconstruction of the fragmented message to fail.

The MAC PDU structure allows only one first fragment or continuation fragment to be sent per MAC block. This shall be sent as the last PDU in the MAC block. In the MAC-RESOURCE PDU that contains the first fragment, the "Length indication" element shall be set to  $11111_2$ .

The BS may abort a fragmented transmission at any time before transmission of MAC-END by sending no more fragments of the message.

If the BS wishes to send slot granting information with a fragmented message, the grant may be included in either the MAC-RESOURCE or the MAC-END PDU.

If the BS wishes to send channel allocation information with a fragmented message, then this information shall be included within the MAC-END PDU and shall not be included within the MAC-RESOURCE PDU.

NOTE 3: For a multi-slot control channel, all the downlink slots comprising that control channel are equivalent. In particular, the continuation and final fragments may be transmitted on any downlink slot appropriate to that channel (as indicated by the "Timeslot Assigned" element from the MAC-RESOURCE or MAC-END PDU that allocated an assigned channel or as indicated by the SYSINFO-DA PDU for a multi-slot MCCH-Q); they are not restricted to the same timeslot number as the first fragment.

#### 23.4.2.1.2 Fragmentation of uplink TM-SDU

When the MS-MAC wishes to send a TM-SDU that does not require fragmentation, it shall send the entire TM-SDU within the MAC-ACCESS PDU or the MAC-DATA PDU or the MAC-U-BLCK PDU (if supported by the BS). The MAC-ACCESS PDU applies if the MS-MAC is using random access or a subslot granted by the BS; the MAC-DATA or MAC-U-BLCK PDU applies if the MS-MAC is using a full slot granted by the BS. After transmission in a granted subslot or slot, the MS-MAC shall inform the LLC that the TM-SDU has been sent (using the TMA-REPORT indication primitive).

For CA, the BS indicates whether it supports the MAC-U-BLCK PDU using the "extended services broadcast" element in the SYSINFO and SYSINFO-Q PDUs. For DA, the BS shall support the MAC-U-BLCK PDU.

The MS-MAC may perform fragmentation of a TM-SDU using any of the following transmission forms:

- i) MAC-ACCESS + MAC-END-HU;
- ii) MAC-ACCESS +  $n \times$  MAC-FRAG + MAC-END  $0 \leq n \leq n_{\max}$ ;
- iii) MAC-DATA + MAC-END-HU;
- iv) MAC-DATA +  $n \times$  MAC-FRAG + MAC-END  $0 \leq n \leq n_{\max}$ .

Form i) or ii) shall apply if the MS-MAC is using random access to start the process or if the MS-MAC is granted a subslot by the BS. Form iii) or iv) shall apply if the transmission starts in a full slot granted by the BS.

NOTE 1: The value of parameter  $n_{\max}$  depends on the modulation, and also the bandwidth and coding rate for QAM, to be used for the reserved access slot(s) containing the MAC-FRAG and MAC-END PDUs; see table 23.8.

When the MS-MAC wishes to send a TM-SDU, it shall first determine whether fragmentation is required and, if so, the required capacity to carry the TM-SDU.

For MAC-ACCESS, fragmentation is required for a TM-SDU exceeding:

- 62 bits if sent by random access on a  $\pi/4$ -DQPSK or D8PSK channel; or
- 35 bits if sent by random access on a QAM channel; or
- $B_{\text{ACCESS}}$  bits if sent by reserved access (see note 2).

If fragmentation is required, the MAC-ACCESS PDU can carry a first fragment of:

- 56 bits of TM-SDU if sent by random access on a  $\pi/4$ -DQPSK or D8PSK channel; or
- 29 bits of TM-SDU if sent by random access on a QAM channel; or
- $(B_{\text{ACCESS}} - 6)$  bits of TM-SDU if sent by reserved access (see note 2).

NOTE 2: The value of parameter  $B_{\text{ACCESS}}$  depends on the modulation, and also the bandwidth and coding rate for QAM, to be used for the reserved access subslot containing the MAC-ACCESS PDU; see table 23.8.

NOTE 3: If the MS is on a QAM channel and is using random access to start the process of sending a TM-SDU exceeding 35 bits, but not exceeding  $B_{\text{ACCESS}}$  bits for the modulation, bandwidth and coding to be used in a reserved access subslot, the MS may choose not to include a first fragment of TM-SDU in the random access message - instead just requesting a reserved subslot in the random access message and then sending the TM-SDU without fragmentation in the granted subslot. This may sometimes be more efficient for channels with high bandwidth.

If the MS is on a D8PSK channel, and is using random access to start the process of sending a TM-SDU exceeding 62 bits, but not exceeding  $B_{\text{ACCESS}}$  bits for  $\pi/8$ -D8PSK, and if the MS intends to use  $\pi/8$ -D8PSK modulation in a reserved access subslot, the MS may choose not to include a first fragment of TM-SDU in the random access message - instead just requesting a reserved subslot in the random access message and then sending the TM-SDU without fragmentation in the granted subslot.

For MAC-DATA, fragmentation is required for a TM-SDU exceeding  $B_{\text{DATA}}$  bits (and the MAC-DATA PDU can carry a first fragment of  $B_{\text{DATA}}$  bits of TM-SDU).

NOTE 4: The value of parameter  $B_{\text{DATA}}$  depends on the modulation, and also the bandwidth and coding rate for QAM, to be used for the reserved access slot containing the MAC-DATA PDU; see table 23.8.

NOTE 5: The above numbers and the numbers in table 23.8 assume that the first fragment is the only PDU within the MAC block. If association has occurred within the subslot or slot, the available size is reduced correspondingly. Fragmentation can only be used after association if the complete MAC header, plus at least one bit of TM-SDU, can be sent within the MAC block.

NOTE 6: The above numbers and the numbers in table 23.8 assume the use of an SSI or SMI in the MAC header. If an event label is used, then the available sizes are increased by 14 bits.

If the remainder of the TM-SDU does not exceed  $B_{\text{END-HU}}$  bits, then the transmission can be completed with a single subslot (MAC-END-HU PDU).

NOTE 7: The value of parameter  $B_{\text{END-HU}}$  depends on the modulation, and also the bandwidth and coding rate for QAM, to be used for the reserved access subslot containing the MAC-END-HU PDU; see table 23.8.

Otherwise, the MS-MAC shall determine the required number ( $N = n + 1$ ) of full slots to send the remainder ( $R$  bits) of the TM-SDU:

- if  $R \leq B_{\text{END}}$ ,  $N = 1$ ;
- if  $R > B_{\text{END}}$ ,  $N = 2 + (R - B_{\text{END}} - 1) \text{ DIV } B_{\text{FRAG}}$ ;

where DIV represents integer division, rounded down.

NOTE 8: The values of parameters  $B_{\text{FRAG}}$  and  $B_{\text{END}}$  depend on the modulation, and also the bandwidth and coding rate for QAM, to be used for the reserved access slot(s) containing the MAC-FRAG and MAC-END PDUs; see table 23.8.

It is not possible to indicate a reservation requirement in a MAC-FRAG PDU, so it will not normally be possible for the MS to change its decision about modulation and coding rate during transmission of the reserved slots containing the MAC-FRAG and MAC-END PDUs. Therefore, when performing fragmentation on a D8PSK or QAM channel, the MS-MAC first needs to decide on the modulation and coding rate that it will use for the transmission of the MAC-FRAG and MAC-END PDUs. It then calculates the required number of slots ( $N$ ) based on that decision.

The MS-MAC shall use the following procedure for sending a fragmented TM-SDU:

- The MS-MAC shall send the first fragment in the MAC-ACCESS or MAC-DATA PDU, setting the "fill bit indication" to indicate that no fill bits are present and the optional elements to include the "Capacity request" indicating:
  - start of fragmentation;
  - the reservation requirement for the remainder of the TM-SDU (and for any other messages which the MS has ready to send for this address on this control channel).

- If the MS-MAC requested only a subslot then it shall send the final fragment in the first subslot or full slot granted for this address on this control channel (using MAC-END-HU or MAC-END respectively). The "fill bit indication" shall be used to indicate whether or not fill bits are used within the PDU.
- If the MS-MAC requested one or more full slots then it shall send further fragments in full slots on this control channel, using  $n$  MAC-FRAG PDUs and then one MAC-END PDU. It shall send fragments in any slots already granted for this address, and in slots as they are granted by the BS for this address (in one or more slot grants).

NOTE 9: The BS is permitted to use more than one slot grant when granting the requested slots for the further fragments, in which case the granted slots need not be continuous on this uplink control channel. However, see timer T.202 in procedure b) below.

- For the first  $n-1$  MAC-FRAG PDUs, the MS-MAC shall include fragments of  $B_{FRAG}$  bits of the TM-SDU (with no fill bits). For the last MAC-FRAG, the MS-MAC shall include the next  $B_{FRAG}$  bits of the TM-SDU, or the remainder of the TM-SDU if this is less than  $B_{FRAG}$  bits (with the "fill bit indication" used to indicate the end of the user data).
- The MS-MAC shall include the remaining part (if any) of the TM-SDU in the MAC-END PDU. The "fill bit indication" shall be used to indicate whether or not fill bits are used within the PDU.

NOTE 10: The ISSI and its associated ASSI are equivalent for the purposes of the slot granting procedure (so the MS should use any subslot or slot(s) granted on its ISSI for a TM-SDU being sent with its ASSI, or vice versa). Similarly, an event label and its corresponding address are equivalent for the purposes of the slot granting procedure. Also, a newly assigned ASSI is equivalent to the replaced ASSI or USSI for the purposes of the slot granting procedure.

The transmission process described above shall be continued until one of the following cases a) to d) occurs:

- a) The MS-MAC sends the MAC-END-HU or MAC-END PDU.

The MS-MAC shall then inform the LLC that the TM-SDU has been sent by reserved access (using the TMA-REPORT indication primitive).

The remainder (if any) of the MAC block shall be completed either by a Null PDU (plus fill bits) or by a MAC-ACCESS or a MAC-DATA or MAC-U-BLCK PDU by association as appropriate.

If the MS has further signalling to send for this address on this control channel, then the MS-MAC shall include the reservation requirement in the MAC-END-HU/MAC-END PDU (or in the last PDU in the MAC block if association is performed).

- b) The MS-MAC does not have any capacity granted for this address on this control channel and a time T.202 has elapsed since:

- it last transmitted a fragment; or
- it last received a "basic slot granting" element for this address on this control channel containing the instruction to "Wait for another Slot Grant",

whichever is the later.

The MS-MAC shall then inform the LLC that the transmission has failed (using the TMA-REPORT indication primitive), and shall discard the TM-SDU.

NOTE 11: After a fragmentation failure, the LLC is responsible for sending a re-transmission if appropriate.

- c) The MS-MAC asked for full slot reservation, and it receives a subslot grant for this address.

The MS-MAC shall then inform the LLC that the transmission has failed (using the TMA-REPORT indication primitive), and shall discard the TM-SDU. The MS-MAC may use the granted subslot to send another TM-SDU.

- d) The MS-MAC receives a TMA-CANCEL request primitive from the LLC, cancelling transmission of this message. In this case, the MS-MAC shall discard the TM-SDU (reporting to the LLC that the message was not completely sent).

If the MS-MAC is granted any further subslots or slots, it may send another TM-SDU.

NOTE 12: Where procedures a), b) and c) use the expression "for this address", the ISSI and its associated ASSI are equivalent for the purposes of this procedure. Similarly, an event label and its corresponding address are equivalent for the purposes of this procedure. Also, a newly assigned ASSI is equivalent to the replaced ASSI or USSI for the purposes of this procedure.

**Table 23.8: Value of parameters in uplink fragmentation procedure**

| Modulation and QAM coding rate and bandwidth for reserved access   | $n_{max}$ | $B_{ACCESS}$          | $B_{DATA}$            | $B_{END-HU}$ | $B_{FRAG}$          | $B_{END}$ |
|--|-----------|-----------------------|-----------------------|--------------|---------------------|-----------|
| $\pi/4$ -DQPSK   | 9         | 62                    | 231                   | 85           | 264                 | 258       |
| $\pi/8$ -D8PSK   | 6         | 118                   | 375                   | 141          | 408                 | 402       |
| 4-QAM rate=1/2, 25 kHz   | 14        | 27                    | 144                   | 50           | 177                 | 171       |
| 16-QAM rate=1/2, 25 kHz  | 6         | 103                   | 344                   | 126          | 377                 | 371       |
| 16-QAM rate=1, 25 kHz  | 3         | 258                   | 747                   | 281          | 780                 | 774       |
| 64-QAM rate=1/2, 25 kHz  | 4         | 179                   | 544                   | 202          | 577                 | 571       |
| 64-QAM rate=2/3, 25 kHz  | 3         | 255                   | 744                   | 278          | 777                 | 771       |
| 64-QAM rate=1, 25 kHz  | 2         | 410                   | 1 147                 | 433          | 1 180               | 1 174     |
| 4-QAM rate=1/2, 50 kHz   | 6         | 111                   | 352                   | 134          | 385                 | 379       |
| 16-QAM rate=1/2, 50 kHz  | 3         | 271                   | 760                   | 294          | 793                 | 787       |
| 16-QAM rate=1, 50 kHz  | 1         | 594                   | 1 579                 | 617          | 1 612               | 1 606     |
| 64-QAM rate=1/2, 50 kHz  | 2         | 431                   | 1 168                 | 454          | 1 201               | 1 195     |
| 64-QAM rate=2/3, 50 kHz  | 1         | 591                   | 1 576                 | 614          | 1 609               | 1 603     |
| 64-QAM rate=1, 50 kHz  | 1         | 914                   | 2 395                 | 937          | 2 428               | 2 422     |
| 4-QAM rate=1/2, 100 kHz  | 3         | 279                   | 768                   | 302          | 801                 | 795       |

| 64-QAM rate=1/2, 100 kHz   | 1         | 935                   | 2 416                 | 958          | 2 449               | 2 443     |
| 64-QAM rate=2/3, 100 kHz   | 0         | 1 263                 | 3 240<br>(see note 1) | 1 286        | n/a<br>(see note 2) | 3 267     |
| 64-QAM rate=1, 100 kHz   | 0         | 1 922                 | 4 891<br>(see note 1) | 1 945        | n/a<br>(see note 2) | 4 918     |
| 4-QAM rate=1/2, 150 kHz  | 2         | 447                   | 1 184                 | 470          | 1 217               | 1 211     |
| 16-QAM rate=1/2, 150 kHz   | 1         | 943                   | 2 424                 | 966          | 2 457               | 2 451     |
| 16-QAM rate=1, 150 kHz   | 0         | 1 938                 | 4 907<br>(see note 1) | 1 961        | n/a<br>(see note 2) | 4 934     |
| 64-QAM rate=1/2, 150 kHz   | 0         | 1 439                 | 3 664<br>(see note 1) | 1 462        | n/a<br>(see note 2) | 3 691     |
| 64-QAM rate=2/3, 150 kHz   | 0         | 1 935                 | 4 904<br>(see note 1) | 1 958        | n/a<br>(see note 2) | 4 931     |
| 64-QAM rate=1, 150 kHz   | 0         | 2 930<br>(see note 1) | 7 387<br>(see note 1) | 2 953        | n/a<br>(see note 2) | 7 414     |
| NOTE 1: In these cases, the complete subslot or slot can carry the maximum permitted size of TM-SDU. Therefore fragmentation will not be needed unless association has occurred within the subslot or slot, in which case the available size may have been reduced sufficiently for fragmentation to be appropriate. |           |                       |                       |              |                     |           |
| NOTE 2: In the cases of $B_{FRAG}$ for which "n/a" is indicated, a MAC-END PDU can always carry the remainder of the TM-SDU after the initial MAC-ACCESS or MAC-DATA, so use of MAC-FRAG is not appropriate.   |           |                       |                       |              |                     |           |

### 23.4.2.1.3 Fragmentation in minimum mode

Fragmentation is possible in minimum mode. However, long delays may be introduced, particularly for fragmentation over more than two MAC blocks. Therefore, an MS or BS may choose not to perform fragmentation during minimum mode, and the BS may (as always) choose not to grant slots to an MS for continuation of a fragmented message.

When in minimum mode, the BS should not attempt fragmentation (other than within one slot on stealing channel STCH) of a message addressed to an MS that is in energy economy or dual watch mode.

**a) Downlink TM-SDU**

The general procedure for downlink fragmentation, described in clause 23.4.2.1.1, applies during minimum mode except that, when sending a fragmented message to an MS, the only MAC blocks that the BS may use for MAC-FRAG or MAC-END are those in the MS's designated minimum mode frame 18 slot. The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every N.203<sup>th</sup> frame 18.

NOTE 1: Not all MSs will receive all AACH blocks, so there is some uncertainty about exactly when a particular MS enters and leaves minimum mode. Therefore, if the BS is in process of sending a fragmented message when it enters or leaves minimum mode, it may prefer to abort the transmission.

NOTE 2: The fragmentation procedure defined above applies only when the MAC-RESOURCE PDU is sent on SCH/F or SCH/HD (in slot 1 of frames 2 to 17 if the downlink is in FACCH or assigned SCCH, or in the MS's minimum mode frame 18 slot). If the MAC-RESOURCE PDU is sent on STCH then the fragmentation procedure defined in clause 23.4.2.1.7 applies.

**b) Uplink TM-SDU**

During minimum mode, the MS-MAC shall follow the defined minimum mode rules for receiving and decoding the downlink for signalling messages (e.g. for receiving slot grants from the BS).

The general procedure for uplink fragmentation, described in clause 23.4.2.1.2, applies (although, since time T.202 is counted in downlink signalling opportunities (as defined in annex B), in minimum mode the absolute time is 18 times its usual value).

**23.4.2.1.4 Fragmentation on time-shared control channel****a) Downlink TM-SDU**

The general procedure for downlink fragmentation, described in clause 23.4.2.1.1, applies on a time-shared MCCH except that, when sending a fragmented message to an MS, the only MAC blocks that the BS may use for MAC-FRAG or MAC-END are those in the reserved frames for this BS, not the common frames. The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every N.203<sup>th</sup> reserved frame.

**b) Uplink TM-SDU**

On a time-shared MCCH, the MS-MAC shall follow the defined rules for receiving and decoding the downlink for signalling messages (e.g. for receiving slot grants from the BS). The normal procedure for uplink fragmentation, described in clause 23.4.2.1.2, applies (although, since time T.202 is counted in downlink signalling opportunities (as defined in annex B), on a time-shared control channel the absolute time is greater than on a non-time-shared channel).

**23.4.2.1.5 Fragmentation on assigned channel if downlink is in SACCH****a) Downlink TM-SDU**

In frames 1 to 17, fragmentation may be performed on the stealing channel within one slot (see clause 23.4.2.1.7). Fragmentation may also be performed on the SACCH in frame 18.

NOTE 1: Long delays may be introduced for fragmentation over more than two frame 18s. Also, transmission of a fragmented message on SACCH should be aborted if the BS needs to send a fragmented message on the STCH of that assigned channel. Therefore, the BS may choose not to perform fragmentation on the SACCH in frame 18.

The general procedure for downlink fragmentation, described in clause 23.4.2.1.1, applies on the SACCH in frame 18 with the following differences:

- 1) When sending a fragmented message on SACCH to an individual MS that is currently transmitting traffic on the uplink, the only MAC blocks that the BS may use for the message are those in the highest numbered downlink slot of the assigned channel, in those frame 18s that the MS is required to receive according to the assigned monitoring pattern(s). The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every N.203'th frame 18 where it is required to receive.

NOTE 2: The above procedure applies only for an individually addressed message. If the BS needs to send a group addressed fragmented message when the downlink is in traffic and an MS is transmitting traffic on the uplink then the BS follows procedure 2).

NOTE 3: If the BS wishes to abort a fragmented transmission on SACCH to an individual MS that is currently transmitting traffic on the uplink, it should either wait for the appropriate number of multiframes (e.g.  $N.203 \times 3$  / number of monitoring patterns) before sending another fragmented message on SACCH or otherwise send a MAC-RESOURCE PDU indicating start of fragmentation in the highest numbered downlink slot of the assigned channel in a frame 18 where the MS is required to receive.

- 2) When sending a fragmented message on SACCH to other MSs, the only MAC blocks that the BS may use for MAC-FRAG or MAC-END are those in the lowest numbered downlink slot of the assigned channel in frame 18. The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every N.203'th frame 18.

NOTE 4: As defined in clause 23.3.1.3, an MS receiving in traffic mode on a multi-slot channel is normally required to receive only the lowest numbered slot in frame 18. Therefore, when sending a fragmented message on SACCH to MS(s) that are receiving in traffic mode on a multi-slot channel, the BS should send the first fragment in the lowest numbered slot of the assigned channel in frame 18. Continuation and final fragments sent on SACCH to any MS that is not transmitting traffic on the uplink may be sent only in the lowest numbered slot of the assigned channel in frame 18.

NOTE 5: The BS should note the procedures used by an MS for reconstruction if the MS switches in or out of traffic transmit mode or sees the downlink leave SACCH (see clause 23.4.3.1.5, paragraph before note 1 and paragraph before note 4).

NOTE 6: In case of propagation errors, there is some uncertainty about exactly when a particular MS sees the channel enter or leave SACCH. Therefore, if the BS is in process of sending a fragmented message when it enters or leaves SACCH, it may prefer to abort the transmission.

#### **b) Uplink TM-SDU**

In frames 1 to 17, if an MS is transmitting traffic on the uplink then it may perform fragmentation on the stealing channel within one slot (see clause 23.4.2.1.7).

Fragmentation may be performed by any MS on the uplink SACCH or FACCH. The general procedure for uplink fragmentation, described in clause 23.4.2.1.2, applies although, since time T.202 is counted in downlink signalling opportunities (as defined in annex B), the absolute time is 18 times its usual value. If a fragmentation on uplink SACCH is being performed by an MS that is transmitting traffic on the uplink then the absolute time of T.202 is also modified by the monitoring pattern(s).

NOTE 7: Time T.202 is counted in downlink signalling opportunities (as defined in annex B). However, the BS may choose to send a slot grant by stealing from the downlink TCH.

### 23.4.2.1.6 Fragmentation on assigned channel if downlink is in FACCH or assigned SCCH

#### a) Downlink TM-SDU

The general procedure for downlink fragmentation, described in clause 23.4.2.1.1, applies when an assigned channel is not in downlink traffic with the following difference:

- When sending a fragmented message to an individual MS that is currently transmitting traffic on the uplink, the only MAC blocks that the BS may use for MAC-FRAG or MAC-END are those in the downlink slots where the MS is required to look for further fragments (as defined in clause 23.4.3.1.6 procedure a). The MS-MAC receiving the fragmented message will discard a partially received TM-SDU if it does not receive a fragment in at least every N.203<sup>th</sup> slot where it is required to look for further fragments.

NOTE: The above procedure applies only for a message individually addressed to an MS that is currently transmitting traffic on the uplink. If the BS needs to send other fragmented messages when the downlink is not in traffic then the BS follows the general procedure for downlink fragmentation (so continuation and final fragments may be transmitted on any downlink slot appropriate to the assigned channel). This applies even if the uplink is in traffic.

#### b) Uplink TM-SDU

In frames 1 to 17, if an MS is transmitting traffic on the uplink then it may perform fragmentation on the stealing channel within one slot (see clause 23.4.2.1.7).

Fragmentation may be performed by any MS on the uplink SACCH or FACCH. The general procedure for uplink fragmentation, described in clause 23.4.2.1.2, applies (although, if a fragmentation on uplink SACCH is being performed by an MS that is transmitting traffic on the uplink then the absolute time of T.202 is modified by the monitoring pattern(s)).

### 23.4.2.1.7 Fragmentation on stealing channel

On the stealing channel STCH, fragmentation is only permitted within one slot. Neither the MS nor the BS shall attempt to perform fragmentation over more than one stolen slot.

The procedure for transmission on STCH (including fragmentation) is described in clause 23.8.4.

### 23.4.2.2 Fill bit addition

Fill bits shall be added when the actual size of the MAC PDU is:

- for a MAC-U-BLCK or MAC-D-BLCK PDU: less than the implicit length of the PDU, or less than the available capacity of the MAC block;
- for the other TMA-SAP PDUs: less than the PDU length indicated in the MAC header, or less than the available capacity of the MAC block.

Fill bit addition applies only to TMA-SAP PDUs.

If fill bits are added, the MAC shall set the "fill bit indication" in the MAC header to 1. In order to add fill bits within a PDU, the MAC shall:

- add a bit "1" immediately following the last bit of the TM-SDU data;
- complete as appropriate with bits set to "0":
  - in the case of a MAC-U-BLCK or MAC-D-BLCK PDU, complete with the required number ( $\geq 0$ ) of bits set to "0" until the size of the PDU corresponds to the implicit length or the available capacity of the MAC block (if that is less than the implicit length);
  - in the case of the other TMA-SAP PDUs:
    - if a length indication is included in the MAC header, then complete with the required number ( $\geq 0$ ) of bits set to "0" until the size of the PDU corresponds to the indicated length or the available capacity of the MAC block (if that is less than the indicated length);

- if a length indication is not included in the MAC header (or if the length indication is set to  $11110_2$ ), then complete with the required number ( $\geq 0$ ) of zeros to fill the MAC block.

Fill bits inserted after a Null PDU to complete the MAC block shall be set to "0", except for the first bit after the Null PDU which shall be set to "1".

When there is not enough space to insert a Null PDU in the remainder of a MAC block, the MAC block shall be completed such that the first bit after the user data shall be set to "1" and the following bits shall be set to "0".

NOTE: In this procedure (i.e. when there is not enough space to insert a Null PDU), the MAC uses the normal method for indicating whether there are fill bits inserted within the last indicated or implicit PDU length. Thus, if the actual size of the last MAC PDU in the MAC block is less than the indicated or implicit PDU length then the MAC sets the "fill bit indication" to 1; if the actual size of the last MAC PDU in the MAC block is equal to the indicated or implicit PDU length then the MAC sets the "fill bit indication" to 0. In either case, the recipient discards the bits added following the end of the indicated or implicit length of the last MAC PDU.

The procedure for fill bit addition is valid for both MS and BS.

### 23.4.2.3 PDU association

PDU association may be used when several small PDUs can be fitted into a single MAC block for transfer across the air interface. The PDUs are independent. And the BS may associate PDUs addressed to different MSs within one MAC block. However, the MS shall not associate PDUs sent using different addresses within one MAC block.

NOTE 1: The MS's ISSI and its associated ASSI are equivalent for the purposes of PDU association by an MS (so the MS is not precluded from performing PDU association for PDUs sent using its ISSI and ASSI). Similarly, an event label and its corresponding address are equivalent for the purposes of PDU association by an MS. Also the MS is not precluded from performing PDU association of PDUs sent using a newly assigned ASSI with PDUs sent using the replaced ASSI or USSI.

However, an MS is not permitted to associate PDUs sent using its SMI with PDUs sent using an SSI within a single MAC block; also an MS is not permitted to associate PDUs from multiple TSI families within a single MAC block. These restrictions may possibly be relaxed in future editions of the present document in the case of the final slot of an MS's requested reserved capacity.

The MS is not permitted to associate PDUs sent using a GSSI with PDUs sent using another address.

The association procedure is illustrated in figure 23.8.

**Figure 23.8: Association of several MAC PDUs in one MAC block**

Each PDU shall contain its own MAC header and each TMA-SAP PDU, except possibly the last in the MAC block, shall indicate the length of the PDU either explicitly or implicitly:

- in the case of a MAC-U-BLCK or MAC-D-BLCK PDU, the length of the PDU is defined implicitly for each modulation type and bandwidth (see clauses 21.4.2.6 and 21.4.3.4);
- for the other TMA-SAP PDUs, the length of the PDU is indicated explicitly, except possibly for the last PDU in the MAC block.

The MAC header of the next PDU shall immediately follow the end of the current PDU. (Within a PDU, fill bits shall be inserted as required.) If there are no more PDUs to follow, a special message (the Null PDU) may be used if it fits within the remaining space in the MAC block. If there are unused bits, they shall follow the rules for fill bit addition.

This procedure is valid for both MS and BS.

In order to associate, the MAC shall:

- a) prepare a PDU:
  - for a MAC-U-BLCK or MAC-D-BLCK PDU, the MAC shall place the relevant MAC header in front of the TM-SDU; the length of the PDU is defined implicitly;
  - for the other TMA-SAP PDUs, the MAC shall place the relevant MAC header in front of the TM-SDU, including the PDU length (except in the cases indicated below); in cases where the PDU length cannot be represented exactly by the defined values of the length indication, the MAC shall round up to the next higher valid value of the length indication (including fill bits to make up the difference between the actual PDU content and the indicated PDU length);
  - for a TMB-SAP PDU, the size of the PDU is implicit from the MAC header and modulation;
- b) if the PDU does not completely fill the MAC block then:
  - if the size of the remainder of the MAC block < appropriate Null PDU size (see below) then the MAC shall complete the MAC block such that the first bit after the user data shall be set to "1" and the following bits shall be set to "0"; or
  - if the size of the remainder of the MAC block  $\geq$  appropriate Null PDU size (see below) then the MAC shall either:
    - repeat step a) with another PDU; or
    - use the Null PDU and complete the remainder (if any) with fill bits.

For the downlink, the Null PDU size to be used for the comparison in b) shall be 16 bits. For the uplink, the comparison in b) shall be performed using the Null PDU size that corresponds to an address length of 24 bits. This is 36 bits in a subslot, or 37 bits in a full slot or on STCH. This rule shall apply even if the MS has been assigned an event label.

Association shall not be performed if the remainder of the MAC block is less than the size of the appropriate Null PDU, even if the MAC has a PDU to send that is shorter than the Null PDU.

NOTE 2: The "length indication" element in the MAC header refers to the size of the complete MAC PDU (rounded up to the next higher valid value of length indication), not to the length of the TM-SDU. The length of the TM-SDU is then known, since the TM-SDU follows immediately after the MAC header.

NOTE 3: The definition of the "length indication" element uses two units Y and Z where, for length indication values up to division point D, the length of the MAC PDU is given in units of Y octets. For length indication values above division point D, the incremental unit of the length indication is Z octets (where  $Z \geq Y$ ). In cases where  $Z > Y$  this definition allows a lower overhead for shorter PDUs.

NOTE 4: Length indications  $11111_2$  (for MAC-ACCESS PDUs) and  $111101_2$  (for MAC-DATA and MAC-RESOURCE PDUs) define a specific length in bits - set to correspond to the normal size of an advanced link data segment on a QAM channel. If this specific length is not appropriate then the required value V of the "length indication" element is as follows:

- if  $\text{BITS} \leq 8 \times Y \times D$  then  $V = 1 + ((\text{BITS} - 1) \text{DIV} (8 \times Y))$
- if  $\text{BITS} > 8 \times Y \times D$  then  $V = 1 + D + ((\text{BITS} - (8 \times Y \times D) - 1) \text{DIV} (8 \times Z))$

where:

- BITS is the PDU size in bits;
- $D = 14$ ,  $Y = Y_1$  and  $Z = Z_1$  when sending a MAC-ACCESS PDU;
- $D = 0$ ,  $Y = Y_1$  and  $Z = Z_1$  when sending a MAC-END-HU PDU;
- $D = 18$ ,  $Y = Y_2$  and  $Z = Z_2$  when sending a MAC-DATA, MAC-RESOURCE or downlink MAC-END PDU;
- $D = 6$ ,  $Y = Y_2$  and  $Z = Z_2$  when sending an uplink MAC-END PDU; and

- DIV represents integer division, rounded down.

The values of  $Y_1$ ,  $Y_2$ ,  $Z_1$  and  $Z_2$  depend on the modulation and the QAM coding rate and the bandwidth of the burst in which the PDU is sent. They are given in clause 21.6.

NOTE 5: There will be some cases when the PDU only just fits within the MAC block so that, after rounding up to the next higher valid value of length indication, the "length indication" element may indicate a value which exceeds the available capacity of the MAC block. Similarly the implicit length may indicate a value which exceeds the available capacity of the MAC block.

NOTE 6: In the present document, the only TMB-SAP PDUs for which association may apply are:

- the ACCESS-DEFINE PDU; and
- the SYSINFO PDU when it is sent using  $\pi/8$ -D8PSK modulation;
- the SYSINFO-Q PDU; and
- the SYSINFO-DA PDU.

The following points apply for TMA-SAP PDUs other than MAC-U-BLCK and MAC-D-BLCK:

- When a BS performs fragmentation, it shall send the first fragment and continuation fragments as the last PDU in a MAC block. Or, when an MS has further signalling to send, it shall include the reservation requirement in the MAC header of the last (non-Null) PDU in a MAC block. In both these cases, the PDU length cannot be indicated in the MAC header. Also, when an MS-MAC does not require to perform association within an uplink subslot, it should not include the "length indication" element in the MAC-ACCESS PDU except when it needs to send the Null PDU in a subslot.
- In all three cases, the PDU shall be deemed to fill the remainder of the MAC block, and the length of the TM-SDU, or TM-SDU fragment, shall be indicated by use of the "fill bit indication" and any fill bits.

For MAC-U-BLCK and MAC-D-BLCK, the length of the PDU is defined implicitly for each modulation type and bandwidth:

- When the PDU is sent using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation, the implicit length is equal to the size of the MAC block, so the MAC-U-BLCK or MAC-D-BLCK PDU is always the last PDU in the MAC block; the PDU size (before removal of fill bits) is equal to:
  - the size of the MAC block if this is the only PDU in the MAC block; or
  - the available capacity of the MAC block if this is not the first PDU in the MAC block.
- When the PDU is sent using QAM modulation with modulation level higher than 4-QAM or for bandwidths of 100 kHz or more, the implicit length is less than the size of the MAC block, so association may apply following the PDU.

## 23.4.3 PDU decomposition for signalling messages

### 23.4.3.1 Reconstruction (TMA-SAP only)

#### 23.4.3.1.0 General

This procedure is the opposite to fragmentation which is performed by the sender as described in clause 23.4.2.1.

#### 23.4.3.1.1 Reconstruction of downlink TM-SDU

The MS-MAC shall attempt to receive and decode the downlink slots appropriate to the relevant control channel (within the constraints of the energy economy or dual watch or part-time reception regime or the napping procedures, and the cell reselection procedures, and linearization and transmission requirements).

On receipt of a MAC-D-BLCK PDU containing one of its valid event labels, the MS-MAC shall deliver the TM-SDU to the LLC using the TMA-UNITDATA indication primitive. Other actions may be performed relating to other elements in the MAC header.

On receipt of a MAC-RESOURCE PDU containing one of its valid addresses or event labels, the MS-MAC shall perform the following actions relating to the TM-SDU. Other actions may be performed relating to other elements in the MAC header.

- a) If the MAC-RESOURCE PDU contains "Length indication"  $\neq 11111_2$ , indicating no fragmentation, then the MS-MAC shall deliver the TM-SDU (if any) to the LLC using the TMA-UNITDATA indication primitive.
- b) If the MAC-RESOURCE PDU contains "Length indication"  $= 11111_2$ , indicating the start of fragmentation, then the MS-MAC shall store the TM-SDU fragment. (The length of the first fragment is indicated only by the "fill bit indication" and any fill bits.)

The MS-MAC shall then receive all the downlink slots on this control channel, looking for continuation fragments or for the end of the fragmented data i.e. MAC-FRAG or MAC-END PDU respectively.

On receipt of a MAC-FRAG PDU, the MS-MAC shall append the TM-SDU fragment to the already received fragment(s). (The length of a continuation fragment is indicated only by the "fill bit indication" and any fill bits.) The MS-MAC shall then continue to receive the control channel, looking for further MAC-FRAG PDUs or for the MAC-END PDU.

On receipt of a MAC-END PDU, the MS-MAC shall append the TM-SDU fragment to the already received fragment(s). (The length of the final fragment is indicated by the combination of the "Length indication", the "fill bit indication" and any fill bits.) The MS-MAC shall then deliver the reconstructed TM-SDU to the LLC using the TMA-UNITDATA indication primitive.

NOTE: Occasionally the MAC-END PDU will contain no user data, in which case the already assembled fragments comprise the complete TM-SDU. On receipt of MAC-END, the MS-MAC delivers the TM-SDU to the LLC.

The MS-MAC shall continue this process until it receives the MAC-END PDU, or until one of the following occurs:

- i) it receives any MAC-RESOURCE PDU on this control channel containing "Length indication"  $= 11111_2$  (for any address, not only one of its own addresses or event labels);
- ii) it fails to decode an SCH MAC block on this control channel (see below);
- iii) it has received N.203 consecutive slots on this control channel without receiving a fragment of its TM-SDU.

In all three cases, the MS-MAC shall discard the partially reconstructed TM-SDU. In case i), if the MAC-RESOURCE PDU contains one of its own addresses or event labels, the MS-MAC shall then continue to process that new PDU.

The MS shall provide adequate buffering to store a fragmented TM-SDU which may be up to N.202 bits in length. The MS-MAC does not deliver any part of the TM-SDU to the LLC until the complete TM-SDU has been received.

The appropriate types of SCH MAC block in criterion ii) shall be:

- an SCH/HD or SCH/F MAC block if the MS is on a  $\pi/4$ -DQPSK channel;
- an SCH/HD, SCH/F, SCH-P8/HD or SCH-P8/F MAC block if the MS is on a D8PSK channel; or
- any SCH-Q/D MAC block or an SCH-Q/B MAC block if the MS is on a QAM channel.

For the purposes of the reconstruction procedure, an MS on a QAM channel shall also regard it as failure to decode an SCH MAC block on this control channel if the MS does not attempt to decode the main part of the slot because it fails to decode the downlink QAM-SLOTINFO PDU or does not understand the value of the "slot format" element in the downlink QAM-SLOTINFO PDU or is not capable of processing slots with the indicated format.

### 23.4.3.1.2 Reconstruction of uplink TM-SDU

On receipt of a MAC-U-BLCK PDU, the BS shall assume that the received TM-SDU is complete.

On receipt of a MAC-ACCESS or MAC-DATA PDU, the BS shall perform the following actions relating to the TM-SDU.

If the received PDU does not indicate start of fragmentation then the BS shall assume that the received TM-SDU is complete.

If the received PDU indicates start of fragmentation, and if the BS decides to grant capacity for the fragmented message, then the BS shall store the TM-SDU fragment. It shall also attempt to receive any subslot or slots granted to the MS for this address on this control channel (either granted already or granted in subsequent MAC-RESOURCE, MAC-END or MAC-D-BLCK PDUs), looking for further fragments of the TM-SDU.

NOTE 1: The MS ISSI and its associated ASSI are equivalent for the purposes of usage of granted slots (so the MS will use any capacity granted on its ISSI for a fragmented message being sent with its ASSI, or vice versa). Similarly, an event label and its corresponding address are equivalent for the purposes of usage of granted slots. Also, a newly assigned ASSI is equivalent to the replaced ASSI or USSI for the purposes of usage of granted slots.

- a) If the MS requested a single subslot, and the BS grants a subslot for a final fragment, then the BS shall inspect the first PDU in that subslot.

If the BS receives the MAC-END-HU PDU, it shall append the TM-SDU fragment to the first fragment, and shall assume that the received TM-SDU is complete.

If the BS receives the MAC-ACCESS PDU, it shall discard the old fragment and shall continue to process the new PDU.

If the BS fails to decode the uplink subslot, it shall discard the old fragment.

- b) If the BS grants full slots to the MS, then it shall attempt to receive those granted slots, looking for the MAC-FRAG or MAC-END PDU.

On receipt of a MAC-FRAG PDU, the BS shall append the TM-SDU fragment to the already received fragment(s). It shall then continue to attempt to receive the granted slots, looking for further MAC-FRAG PDUs or for the MAC-END PDU.

On receipt of a MAC-END PDU, the BS shall append the TM-SDU fragment to the already received fragment(s), and shall assume that the received TM-SDU is complete.

NOTE 2: Occasionally the MAC-END PDU will contain no user data, in which case the already assembled fragments comprise the complete TM-SDU.

The BS may continue this process (granting more slots if appropriate) until it receives the MAC-END PDU, or until one of the following occurs:

- i) it receives a MAC-DATA or MAC-U-BLCK PDU in one of the granted slots;
- ii) it fails to decode a MAC block in one of the granted slots;
- iii) it has not granted slots to the MS nor sent the instruction to "Wait for another Slot Grant", and a time T.202 has elapsed since the last slot granted to the MS on this control channel (see clause 23.4.2.1.2).

In all three cases, the BS shall discard the partially reconstructed TM-SDU. In case i), the BS shall continue to process the new PDU. In case ii), the BS shall discard any MAC-FRAG or MAC-END PDUs received in any further slots granted to this MS for this address (until receipt of the next MAC-ACCESS, MAC-DATA or MAC-U-BLCK PDU from the MS).

If, at any time, the BS receives a MAC-FRAG, MAC-END or MAC-END-HU PDU in a granted slot or subslot, without a corresponding start of fragmentation from this MS (on this control channel), the BS shall discard the PDU.

NOTE 3: After receiving a fragmented TM-SDU containing a BL-DATA or BL-ADATA message, the BS may choose to send the LLC acknowledgement more than once (for reliability).

### 23.4.3.1.3 Reconstruction in minimum mode

#### a) Downlink TM-SDU

During minimum mode, the MS-MAC shall follow the defined minimum mode rules for receiving and decoding the downlink for signalling messages in frames 1 to 17 and in frame 18.

The normal procedure for reconstruction of a downlink TM-SDU, described in clause 23.4.3.1.1, generally applies except that, after the MS-MAC receives a MAC-RESOURCE PDU addressed to itself and containing a start of fragmentation, the procedure b) of clause 23.4.3.1.1 for looking for continuation fragments (MAC-FRAG) or for the end of the fragmented data (MAC-END) shall apply only to the MS's designated minimum mode frame 18 slot.

Also, the normal criteria ii) and iii) of clause 23.4.3.1.1 for discarding a partially reconstructed TM-SDU shall be replaced by the following criteria ii) and iii):

- ii) it fails to decode an SCH MAC block in its designated minimum mode frame 18 slot;
- iii) it has received its designated minimum mode slot in N.203 consecutive frame 18s without receiving a fragment of its TM-SDU.

On leaving minimum mode, the MS-MAC shall return to the normal method of reconstruction (i.e. looking for fragments in all downlink slots on the MCCH).

NOTE 1: The above minimum mode procedure applies only to those MSs that are in common control mode and receiving the MCCH. It does not apply to MSs on an assigned channel.

NOTE 2: While receiving a fragmented message during minimum mode, the MS-MAC is still required to receive slot 1 of frames 2 to 17, e.g. it may be sent a non-fragmented message. As defined in criterion i) of clause 23.4.3.1.1, the MS discards the partially reconstructed message if it receives any MAC-RESOURCE PDU on this channel containing "Length indication" = 111111<sub>2</sub> (i.e. start of fragmentation).

NOTE 3: The reconstruction procedure defined above applies only when the MAC-RESOURCE PDU was sent on SCH/F or SCH/HD (in slot 1 of frames 2 to 17 if the downlink is in FACCH or assigned SCCH, or in the MS's minimum mode frame 18 slot). If the MAC-RESOURCE PDU was sent on STCH then the reconstruction procedure defined in clause 23.4.3.1.7 applies.

#### b) Uplink TM-SDU

The normal procedure for reconstruction of an uplink TM-SDU, described in clause 23.4.3.1.2, applies during minimum mode.

### 23.4.3.1.4 Reconstruction on time-shared control channel

#### a) Downlink TM-SDU

On a time-shared MCCH, the MS-MAC shall follow the defined rules for receiving and decoding the downlink for signalling messages.

The normal procedure for reconstruction of a downlink TM-SDU, described in clause 23.4.3.1.1, generally applies except that, after the MS-MAC receives a MAC-RESOURCE PDU addressed to itself and containing a start of fragmentation, the procedure b) of clause 23.4.3.1.1 for looking for continuation fragments (MAC-FRAG) or for the end of the fragmented data (MAC-END) shall apply only to slot 1 of the reserved frames for this BS, not to the common frames.

Also, the normal criteria ii) and iii) of clause 23.4.3.1.1 for discarding a partially reconstructed TM-SDU shall be replaced by the following criteria ii) and iii):

- ii) it fails to decode an SCH MAC block in slot 1 of one of the reserved frames for this BS;
- iii) it has received slot 1 of N.203 consecutive reserved frames for this BS without receiving a fragment of its TM-SDU.

NOTE: While receiving a fragmented message, the MS-MAC is still required to attempt to receive and decode slot 1 of the common frames, e.g. it may be sent a non-fragmented message.

For a time-shared common SCCH, "slot 1" in the above shall be replaced by the appropriate slot number on the main carrier.

**b) Uplink TM-SDU**

The normal procedure for reconstruction of an uplink TM-SDU applies.

**23.4.3.1.5 Reconstruction on assigned channel if downlink is in SACCH**

**a) Downlink TM-SDU**

In frames 1 to 17, reconstruction of downlink STCH may apply (see clause 23.4.3.1.7).

The normal procedure for reconstruction of a downlink TM-SDU, described in clause 23.4.3.1.1, generally applies for a message sent on the SACCH in frame 18 with the following differences:

- 1) If an MS that is transmitting traffic on the uplink receives a MAC-RESOURCE PDU in frame 18 of the assigned channel, individually addressed to itself and containing a start of fragmentation, the procedure b) of clause 23.4.3.1.1 for looking for continuation fragments (MAC-FRAG) or for the end of the fragmented data (MAC-END) shall apply only to the highest numbered downlink slot of the assigned channel in those frame 18s indicated by the assigned monitoring pattern(s).

Also, the normal criteria ii) and iii) of clause 23.4.3.1.1 for discarding a partially reconstructed TM-SDU shall be replaced by the following criteria ii) and iii):

- ii) it fails to decode an SCH MAC block in the highest numbered downlink slot of the assigned channel in a frame 18 indicated by the assigned monitoring pattern(s);
- iii) it has received the highest numbered downlink slot of the assigned channel in N.203 consecutive frame 18s indicated by the assigned monitoring pattern(s) without receiving a fragment of its TM-SDU.

If the MS switches out of traffic transmit mode, it reverts to procedure 2). Or, if the downlink leaves SACCH, the MS reverts to the procedure for reconstruction when the downlink is in FACCH.

NOTE 1: For a single-slot channel, the highest numbered downlink slot of the assigned channel is implicitly the one slot of the assigned channel, as defined by element "timeslot assigned".

NOTE 2: For a simplex call, the transmitting MS recognizes that the downlink is in SACCH by using the ACCESS-ASSIGN PDU as defined in clause 23.5.6.3. For a duplex call, the duplex traffic transmit permission included traffic receive permission and thus indicated that the downlink is in SACCH.

NOTE 3: The reconstruction procedure defined above applies only for a message individually addressed to an MS that is transmitting traffic on the uplink. If the MS receives the start of a group addressed fragmented message then it should either discard the TM-SDU fragment or continue the reconstruction using procedure 2).

- 2) If an MS that is not transmitting traffic on the uplink receives a MAC-RESOURCE PDU in frame 18 of the assigned channel, addressed to itself and containing a start of fragmentation, the procedure b) of clause 23.4.3.1.1 for looking for continuation fragments (MAC-FRAG) or for the end of the fragmented data (MAC-END) shall apply only to the lowest numbered downlink slot of the assigned channel in frame 18.

Also, the normal criteria ii) and iii) of clause 23.4.3.1.1 for discarding a partially reconstructed TM-SDU shall be replaced by the following criteria ii) and iii):

- ii) it fails to decode an SCH MAC block in the lowest numbered downlink slot of the assigned channel in frame 18;
- iii) it has received the lowest numbered downlink slot of the assigned channel in N.203 consecutive frame 18s without receiving a fragment of its TM-SDU.

If the MS switches into traffic transmit mode, it reverts to procedure 1). Or, if the downlink leaves SACCH, the MS reverts to the procedure for reconstruction when the downlink is in FACCH.

NOTE 4: Procedure 2) applies both to MSs receiving traffic on the channel in a simplex call and to any MSs not in traffic mode. The use of only the lowest numbered downlink slot in frame 18 for MAC-FRAG and MAC-END means that an MS receiving in traffic mode on a multi-slot channel is not required to modify its reception pattern during the reconstruction.

For a single-slot channel, the lowest numbered downlink slot of the assigned channel is implicitly the one slot of the assigned channel, as defined by element "timeslot assigned".

NOTE 5: If the MS is receiving traffic on the channel then the traffic receive permission informed it that the downlink is in SACCH. If the MS is not in traffic mode on the channel then it recognizes that the downlink is in SACCH (i.e. carrying traffic for other MSs) by using the ACCESS-ASSIGN PDU as defined in clause 23.5.6.3.

NOTE 6: In procedure 1), while receiving a fragmented message on SACCH, the MS-MAC also receives in frames 1 to 17 when appropriate. In procedure 2), while receiving a fragmented message on SACCH, the MS-MAC also receives in frames 1 to 17. In either case, the MS may be sent a non-fragmented message on STCH. And, as defined in criterion i) of clause 23.4.3.1.1, the MS discards the partially reconstructed message if it receives any MAC-RESOURCE PDU on this assigned channel containing "Length indication" =  $111111_2$  (i.e. start of fragmentation).

#### b) Uplink TM-SDU

If the uplink is in traffic then, in frames 1 to 17, reconstruction of uplink STCH may apply (see clause 23.4.3.1.7).

The normal procedure for reconstruction of an uplink TM-SDU, described in clause 23.4.3.1.2, applies on uplink SACCH or FACCH.

### 23.4.3.1.6 Reconstruction on assigned channel if downlink is in FACCH or assigned SCCH

#### a) Downlink TM-SDU

The normal procedure for reconstruction of a downlink TM-SDU, described in clause 23.4.3.1.1, generally applies when an assigned channel is not in downlink traffic with the following differences for an MS that is transmitting traffic on the uplink:

- If an MS that is transmitting traffic on the uplink receives a MAC-RESOURCE PDU individually addressed to itself and containing a start of fragmentation, the procedure b) of clause 23.4.3.1.1 for looking for continuation fragments (MAC-FRAG) or for the end of the fragmented data (MAC-END) shall apply only to those slots where the MS is required to look for further fragments (as defined below).

Also, the normal criteria ii) and iii) of clause 23.4.3.1.1 for discarding a partially reconstructed TM-SDU shall be replaced by the following criteria ii) and iii):

- ii) it fails to decode an SCH MAC block in one of the slots where it is required to look for further fragments;
- iii) it has received N.203 consecutive slots where it is required to look for further fragments without receiving a fragment of its TM-SDU.

For a single-slot channel, the "slots where the MS is required to look for further fragments" (as used above) shall comprise the downlink slot, as defined by element "timeslot assigned", in those frames indicated by the assigned monitoring pattern(s).

For a frequency half duplex MS transmitting traffic on a multi-slot channel, the "slots where the MS is required to look for further fragments" (as used above) shall comprise:

- in frames 1 to 17: no slots; and
- in frame 18: the highest numbered downlink slot of the assigned channel, in those frame 18s indicated by the assigned monitoring pattern(s).

For a frequency full duplex MS transmitting traffic on a multi-slot channel, the "slots where the MS is required to look for further fragments" (as used above) shall comprise:

- in frames 1 to 17: all slots of the downlink assigned channel, as defined by element "timeslot assigned", in those frames indicated by the assigned monitoring pattern(s); and
- in frame 18: the highest numbered downlink slot of the assigned channel, in those frame 18s indicated by the assigned monitoring pattern(s).

NOTE 1: The reconstruction procedure defined above for a frequency half duplex MS transmitting traffic on a multi-slot channel applies even if the MS has fast switching capability.

NOTE 2: The reconstruction procedure defined above applies only for a message individually addressed to an MS that is transmitting traffic on the uplink. If the MS receives the start of a group addressed fragmented message then it should either discard the TM-SDU fragment or continue the reconstruction using the normal procedure defined in clause 23.4.3.1.1 (i.e. overriding the monitoring pattern information and assuming that continuation and final fragments may be transmitted on any downlink slot appropriate to the assigned channel).

NOTE 3: The normal reconstruction procedure defined in clause 23.4.3.1.1 applies for MSs that are not currently transmitting traffic on the uplink. So continuation and final fragments may be transmitted on any downlink slot appropriate to the assigned channel.

#### b) Uplink TM-SDU

If the uplink is in traffic then, in frames 1 to 17, reconstruction of uplink STCH may apply (see clause 23.4.3.1.7).

The normal procedure for reconstruction of an uplink TM-SDU, described in clause 23.4.3.1.2, applies on uplink SACCH or FACCH.

#### 23.4.3.1.7 Reconstruction on stealing channel

On the stealing channel STCH, fragmentation is only permitted within one timeslot. The procedure for reception of STCH (including reconstruction within the two half slots of one stolen timeslot) is described in clause 23.8.4.

#### 23.4.3.2 Fill bit deletion

On receipt of a TMA-SAP PDU, the MAC shall check whether fill bits are present ("fill bit indication" set to 1 in the PDU header). If fill bits are present, the MAC shall:

- inspect the last bit of the PDU;
- if the last bit is "1", remove this bit; then the rest of the data is the true PDU content;
- if the last bit is "0", remove this bit and all preceding zeros until a bit "1" is found; remove this bit "1"; then the rest of the data is the true PDU content.

NOTE: The maximum number of fill bits to remove is normally  $(8Z_1 - 1)$  bits for a PDU in a subslot, or  $(8Z_2 - 1)$  bits for a PDU in a slot, if a specific length indication is given in the MAC header. (The values of  $Z_1$  and  $Z_2$  are given in clause 21.6.) It may be a larger number in the case of an implicit length indication (i.e. for MAC-U-BLCK or MAC-D-BLCK) or, for the other TMA-SAP PDUs, if there is no length indication or if the length indication is set to  $11111_2$  or  $111101_2$  or  $111110_2$ .

Fill bits used for completing a MAC block after the Null PDU, or if there is not enough space for a Null PDU, shall be discarded.

The procedure for fill bit deletion is valid for both MS and BS.

### 23.4.3.3 PDU dissociation

PDU dissociation shall be used when several small PDUs have been fitted into a single MAC block by the association procedure.

Each TMA-SAP PDU (except possibly the last in the MAC block) indicates the length of the PDU - either explicitly or, in the case of a MAC-U-BLCK or MAC-D-BLCK PDU, implicitly. The MAC header of the next PDU immediately follows the end of the current PDU as indicated by the "length indication" element or the implicit length. So separation of PDUs from each other relies on the "length indication" contained in the first MAC header or the implicit length of the first MAC PDU, then the "length indication" contained in the second MAC header or the implicit length of the second MAC PDU, and so on. The Null PDU indicates that there is no more useful data in this MAC block; after receipt of the Null PDU, the MAC shall not look for further information in the block. If the remaining size in the MAC block is less than the length of the Null PDU, the MAC shall discard the remaining bits.

This procedure is valid for both MS and BS.

In order to dissociate, the MAC shall:

- decode the first MAC header and determine the length of the PDU:
  - for a MAC-U-BLCK or MAC-D-BLCK PDU, the length of the PDU is defined implicitly;
  - for the other TMA-SAP PDUs, the MAC shall extract the PDU length indication (if included); if there is no length indication, the PDU size shall be deemed to be the remainder of the MAC block;
  - for a TMB-SAP PDU, the exact size of the PDU is implicit from the MAC header and modulation (see note 1);
- remove any fill bits contained in the PDU, if indicated by the "fill bit indication";
- repeat the above steps until a Null PDU is found or the remaining space in the block is less than the size of the appropriate Null PDU (see note 2).

Each separate PDU shall then be further processed by the MAC.

There will be some cases when the "length indication" or implicit length will indicate a value which exceeds the available capacity of the MAC block. The recipient MAC shall regard the length of the PDU as either the available capacity of the MAC block or the indicated or implicit length, whichever is the lesser. In either case, fill bits shall be removed if the "fill bit indication" is set to 1.

NOTE 1: Some CA MSs may not understand the SYSINFO-DA PDU and therefore will not know the length of the SYSINFO-DA PDU - so cannot process associated PDUs following the SYSINFO-DA PDU in a downlink MAC block.

NOTE 2: The size of the appropriate Null PDU (as used above) is 16 bits for the downlink, 36 bits for an uplink subslot, or 37 bits for an uplink full slot or uplink STCH.

### 23.4.3.4 PDU error detection

The purpose of the CRC added to a MAC block by the lower MAC is to enable the MAC at the receiving side of the air interface to detect whether errors have been introduced into the message during transmission. Therefore, the receiving lower MAC shall extract the decoded CRC and shall calculate a CRC on the remainder of the data as in the transmitting case. The two CRCs shall be compared. If they are not identical, the CRC fail parameter in the TMV-UNITDATA indication primitive shall inform the receiving upper MAC that an error has occurred.

Upon reception of a MAC block as indicated with the CRC fail parameter in the TMV-UNITDATA indication primitive, the upper MAC shall discard the incoming data. However, the upper MAC may use the CRC fail information to update its statistics on error measurement.

Upon reception of a MAC block as indicated with the CRC pass parameter in the TMV-UNITDATA indication primitive, the upper MAC shall further check that the incoming PDU or PDUs are valid by inspecting the MAC headers.

The lower MAC also performs error detection on the AACH and AACH-Q MAC blocks.

Upon reception of an AACH or AACH-Q MAC block as indicated with the CRC fail parameter in the TMV-UNITDATA indication primitive, the upper MAC shall discard the data in that AACH or AACH-Q MAC block. However, the upper MAC in a CA MS uses the AACH or AACH-Q failure information to update its RDC, RDC-NC or RDC-Q statistics; the upper MAC in a DA MS uses the AACH or AACH-Q failure information to update its RDC-DA, RDC-DA-Q or RDC-DA-P statistics; see clause 23.7.3.1.1.

Upon reception of an AACH or AACH-Q MAC block as indicated with the CRC pass parameter in the TMV-UNITDATA indication primitive, the upper MAC shall process the data in that AACH or AACH-Q MAC block. The upper MAC in a CA MS also uses the AACH or AACH-Q success information to update its RDC, RDC-NC or RDC-Q statistics; the upper MAC in a DA MS uses the AACH or AACH-Q success information to update its RDC-DA, RDC-DA-Q or RDC-DA-P statistics; see clause 23.7.3.1.1.

## 23.4.4 Power control

### 23.4.4.1 Overall process

Adaptive RF power control shall be used by the MS. It allows the system to minimize the transmit power required by the MS whilst maintaining the quality of the radio uplink. By minimizing the transmit power levels, interference to co-channel and adjacent channel users is reduced and MS power consumption could be reduced.

Two methods of adaptive RF power control may be used:

- The first method, known as open loop power control, shall be implemented in the MS. Using this method, the MS shall adjust its transmit power based on the power level or equivalent signal quality being received by the MS on the downlink from the BS.
- The second method, known as closed loop power control, shall be supported by the MS if it supports circuit mode traffic transmission (i.e.  $\pi/4$ -DQPSK circuit mode voice calls and/or  $\pi/4$ -DQPSK circuit mode data calls) and may be implemented in the BS. Using this method, the MS shall adjust its transmit power as instructed by the BS. The BS shall calculate the optimal MS transmit power, for example based upon the power level being received on the uplink from that MS. The exact method of measurement and calculation in the BS are outside of the scope of the present document.

These methods are described in more detail in the following clauses. Adaptive RF power control shall not be used to control the BS transmit power.

### 23.4.4.2 MS open loop power control

#### 23.4.4.2.1 Obtaining values of MS\_TXPWR\_MAX\_CELL and ACCESS\_PARAMETER

The MS open loop power control procedure uses two parameters: MS\_TXPWR\_MAX\_CELL and ACCESS\_PARAMETER (see clause 23.4.4.2.2). These parameters are broadcast by the BS:

- in the SYSINFO PDU broadcast by the BS on a  $\pi/4$ -DQPSK or D8PSK channel;
- in the SYSINFO-Q PDU broadcast by the BS to CA MSs on a QAM channel;
- in the SYSINFO-DA PDU broadcast by the BS to DA MSs on a QAM channel.

Also, MS\_TXPWR\_MAX\_CELL for the DA main carrier is included in the SYNC-DA PDU broadcast by the BS to DA MSs on a QAM channel.

The values of these parameters may vary according to the modulation mode and bandwidth of the channel (and according to whether the channel is conforming, non-conforming concentric, sectored, super-sectored or eccentric):

- when an MS first acquires a CA main carrier or receives a channel allocation for a  $\pi/4$ -DQPSK channel on a CA new cell, or when a CA MS is sent to a new  $\pi/4$ -DQPSK channel within the cell or returns to the MCCH or to a  $\pi/4$ -DQPSK common SCCH, it shall make the assumptions specified in clause 23.6.6.1 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;
- when a CA MS is sent to a D8PSK channel, it shall make the assumptions specified in clause 23.6.6.2 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;

- when a CA MS is sent to a QAM channel, it shall make the assumptions specified in clause 23.6.6.3 about the values of these parameters until updated by receiving SYSINFO-Q PDUs on that channel;
- when an MS first acquires a DA main carrier or receives a channel allocation for a QAM channel on a DA new cell, or when a DA MS is sent to a new QAM channel within the cell or returns to the MCCH-Q or to a QAM common SCCH, it shall make the assumptions specified in clause 23.6.11.1 about the values of these parameters until updated by receiving SYSINFO-DA (or SYNC-DA) PDUs on that channel;
- when a DA MS is sent to a  $\pi/4$ -DQPSK channel, it shall make the assumptions specified in clause 23.6.11.2 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;
- when a DA MS is sent to a D8PSK channel, it shall make the assumptions specified in clause 23.6.11.3 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel.

#### 23.4.4.2.2 MS open loop power control procedure

Open loop power control shall be implemented in the MS. The power level shall be controlled for all transmitted bursts except random access messages for which power level control may be based only on the MS\_TXPWR\_MAX\_CELL parameter (and the bandwidth when on a QAM channel).

An MS, when camped on a cell, shall obtain the appropriate values of the MS\_TXPWR\_MAX\_CELL and ACCESS\_PARAMETER parameters for the current channel as specified in clause 23.6.6.

For any reserved access or traffic transmissions, the MS shall use the transmit power level supported by the MS that is the closest to  $P_{MS}$ , where  $P_{MS}$  is defined by:

$$P_{MS} = \text{MIN} ( \text{MS\_TXPWR\_MAX\_CELL}, \text{ACCESS\_PARAMETER} - \text{RSSI} ) \quad (23.1)$$

where: MS\_TXPWR\_MAX\_CELL = Maximum MS transmit power allowed on that channel;

ACCESS\_PARAMETER = Parameter for transmit power calculation on that channel;

RSSI = Averaged signal level received by the MS or an equivalent signal quality measurement.

All values are expressed in dBm. The nominal MS power control level shall not exceed the maximum MS transmit power indicated in the MS\_TXPWR\_MAX\_CELL parameter for that channel.

NOTE: ACCESS\_PARAMETER is based on BS power and configuration and on the required mean power level received at the BS. On a D8PSK channel, it is expected that the BS will set the ACCESS\_PARAMETER so that the MS power is not reduced below a level that would allow the MS to use  $\pi/8$ -D8PSK modulation for some data categories. On a QAM channel, it is expected that the BS will set the ACCESS\_PARAMETER so that the MS power is not reduced below a level that would allow the MS to use the highest permitted uplink bit rate (with the possible exception of coding rate  $r = 1$ ) for some data categories.

The MS, while receiving traffic or signalling, shall update  $P_{MS}$  for the current channel at least every 30 s and, in case of modification, may linearize on a subslot provided for common linearization (CLCH or CLCH-Q).

The MS, while transmitting, shall update  $P_{MS}$  at least every 3 s based upon its RSSI measurements. The MS shall adjust its transmit power to the level supported by the MS that is the closest to  $P_{MS}$ , at the latest, immediately following the next common linearization opportunity on that channel.

In the case of a random access transmission:

- when on a 25 kHz channel, the MS may increase its nominal transmit power to a level supported by the MS that does not exceed the MS\_TXPWR\_MAX\_CELL parameter for this channel in order to increase the probability of the random access transmission reaching the BS without being corrupted;
- when on a QAM channel with bandwidth greater than 25 kHz, the nominal MS transmit power for a random access transmission shall not exceed  $\text{MS\_TXPWR\_MAX\_CELL} - 10 \log_{10} ( B / 25 )$ , where:

MS\_TXPWR\_MAX\_CELL = Maximum MS transmit power allowed on that channel;

B = bandwidth of the QAM channel in kHz.

### 23.4.4.3 MS closed loop power control

Closed loop power control may be employed by a BS in order to control the power of an MS transmitting in circuit mode on a traffic channel.

NOTE 1: Closed loop power control therefore applies only on a  $\pi/4$ -DQPSK channel.

The MS shall obey power control messages from the BS while the MS-MAC is transmitting in U-plane mode. Such power control instructions shall be obeyed only for the duration of that U-plane transmission after which the MS shall revert to open loop power control for subsequent transmissions.

When the MS-MAC switches from C-plane to U-plane transmission mode, or at any time during the U-plane transmission, the BS may control the MS transmit power by sending a MAC-RESOURCE PDU which includes the optional "power control" element, to instruct the MS to increase or decrease its transmit power by the appropriate number of steps (or remain at its current power level, see note 2). A step is equal to 5 dB except that, if an MS with a power class "L" is currently transmitting at its maximum transmit power, then the first step is 2,5 dB; see clause 6.4.1.2.

NOTE 2: The step size is always 5 dB for an MS that is not using a power class "L". It is also 5 dB for an MS with a power class "L" for steps other than the first step down from its maximum transmit power. The 2,5 dB first step for an MS with a power class "L" enables the MS to step down onto one of the nominal MS power control levels defined in clause 6.4.1.2.

The MS shall obey these power control instructions. If the MS is instructed to increase its power above the maximum transmit power of that MS then it shall set its power to the maximum transmit power. Similarly, if it is instructed by the BS to set its power below the minimum power control level of 15 dBm, then it shall set its power to 15 dBm. The MS shall adjust its power after receiving a power control message, at the latest, immediately following the next common linearization opportunity. This power level shall take precedence over open loop power control and shall be used for all subsequent traffic and signalling transmissions, including any transmissions in frame 18, for the duration of the U-plane transmission until one of the following events occurs:

- a) the MS ends its transmission and switches out of U-plane mode; or
- b) the MS receives a MAC-RESOURCE PDU with the "power control" element set to "Revert to open loop power control".

Then the MS shall revert to using the rules defined for open loop power control as defined in clause 23.4.4.2. During closed loop power control operation, the MS shall continue to maintain its RSSI estimate for the downlink so that  $P_{MS}$  is always up to date.

NOTE 3: A power control message may instruct the MS to increase or decrease its transmit power. Alternatively, a "power control" element set to "No change in power" (value 0000<sub>2</sub>) instructs the MS to remain at its current power level, with that power level taking precedence over open loop power control until event a) or b) occurs.

## 23.4.5 MS linearization

### 23.4.5.1 MS linearization on $\pi/4$ -DQPSK or D8PSK channel

The ACCESS-ASSIGN PDU on the AACH shall indicate those uplink subslots that are available for common use for linearization. The MS may linearize its transmitter using any subslot that is indicated as a "CLCH(-Q) subslot", without regard to the access code or common/assigned designation, and even on another physical channel.

NOTE 1: If the ACCESS-ASSIGN PDU contains only one access field, and that access field indicates "CLCH(-Q) subslot", the MS assumes that subslot 1 may be used for linearization and that subslot 2 is reserved; see clause 23.5.1.4.2.

In addition, during frame 18, the MS may linearize on the first subslot of the uplink slot defined by (in accordance with clause 9):

CLCH mapped if:

$$FN = 18 \text{ and } (MN + TN) \bmod 4 = 3 \quad (23.2)$$

This provides a linearization opportunity at least every four multiframe periods on each of the four physical channels of a carrier. The MS may linearize during these subslots without checking the ACCESS-ASSIGN PDU contents but the BS should set the ACCESS-ASSIGN PDU appropriately to indicate a CLCH opportunity.

If the BS is using discontinuous operation then the usage of this mapping is restricted for CA MSs as follows:

- if the BS is using carrier sharing then the MS may linearize using this mapping without checking the ACCESS-ASSIGN PDU contents only on an assigned channel or on a common control channel that it is receiving;
- if the BS is using MCCH sharing then the MS may linearize using this mapping without checking the ACCESS-ASSIGN PDU contents only on an assigned channel, or on a common control channel that it is receiving but restricted to those frame 18s that are reserved frames for this BS;
- if the BS is using traffic carrier sharing then the MS may linearize using this mapping without checking the ACCESS-ASSIGN PDU contents only on the main carrier or on an assigned channel.

For DA, if the BS is using phase modulation carrier sharing, DA MSs on a  $\pi/4$ -DQPSK or D8PSK assigned channel may linearize using this mapping without checking the ACCESS-ASSIGN PDU contents only on that assigned channel.

The MS shall keep adequately linearized, so that it is ready at any time to send a message on the current uplink RF carrier (for example, a response to a BS paging message) without first needing to use a CLCH subslot. This rule shall apply even while the MS is in energy economy or napping mode.

However, an exception is in the case of a dual watching MS which sometimes may not be able to maintain adequate V+D linearization during a Direct Mode call (see ETSI EN 300 396-3 [22], clause 8.4.7.10). Then the MS may, if necessary, use the first subslot of an individually addressed slot grant for linearization. If it does this then it shall maintain adequate V+D linearization on that carrier for at least the next 4 multiframe periods in order to be able to send a message by reserved access if required.

NOTE 2: If the dual watching MS uses the first subslot of an individually addressed slot grant for linearization then, for a single-slot grant, it should not transmit in the second subslot of that slot; for a grant of more than one slot, it should not transmit in the second subslot of the first granted slot but then should send a V+D message in at least the second granted slot.

### 23.4.5.2 MS linearization on QAM channel

The ACCESS-ASSIGN PDU on the AACH-Q shall indicate those uplink subslots that are available for common use for linearization. The MS may linearize its transmitter using any subslot that is indicated as a "CLCH(-Q) subslot", without regard to the access code or common/assigned designation, and even on another QAM physical channel.

NOTE 1: If the ACCESS-ASSIGN PDU contains one access field, and that access field indicates "CLCH(-Q) subslot", the MS assumes that subslot 1 may be used for linearization and that subslot 2 is reserved; see clause 23.5.1.4.2.

If the ACCESS-ASSIGN PDU is not present within the AACH-Q, the MS shall regard the corresponding uplink subslots as not available for common use for linearization.

In addition, during frame 18, the MS may linearize on the first subslot of the uplink slot defined by (in accordance with clause 9):

For MSs in assigned mode on a single-slot QAM channel (both CA MSs and DA MSs), CLCH-Q mapped if:

$$FN = 18 \text{ and } (MN + TN) \bmod 4 = 3 \text{ and } TN \text{ is the allocated timeslot} \quad (23.3)$$

For MSs in assigned mode on a multi-slot QAM channel (both CA MSs and DA MSs), CLCH-Q mapped if:

$$FN = 18 \text{ and } (MN + TN) \bmod 4 = 3 \text{ and } TN \text{ is the lowest numbered timeslot of the allocated channel} \quad (23.4)$$

For DA MSs in common mode on a one-slot common control channel, CLCH-Q mapped if:

$$FN = 18 \text{ and } (MN + TN) \bmod 4 = 3 \text{ and } TN \text{ is the common control timeslot} \quad (23.5)$$

For DA MSs in common mode on a multi-slot MCCH-Q, CLCH-Q mapped if:

$$FN = 18 \text{ and } (MN + 1) \bmod 4 = 3 \text{ and } TN = 1 \quad (23.6)$$

This provides a linearization opportunity at least every four multiframe periods on the QAM channel. The MS may linearize during these subslots without checking the ACCESS-ASSIGN PDU presence and contents but the BS should set the ACCESS-ASSIGN PDU appropriately to indicate a CLCH-Q opportunity.

NOTE 2: If the channel is a multi-slot QAM assigned channel, and  $FN = 18$  and  $(MN + TN) \bmod 4 = 3$  and  $TN$  is not the lowest numbered timeslot of the allocated channel, then CLCH-Q is not mapped.

Similarly, if the channel is a multi-slot MCCH-Q, and  $FN = 18$  and  $(MN + TN) \bmod 4 = 3$  and  $TN$  is not equal to 1, then CLCH-Q is not mapped.

The MS shall keep adequately linearized, so that it is ready at any time to send a message on the uplink QAM channel without first needing to use a CLCH-Q subslot. This rule shall apply even when the MS is in energy economy or part-time reception or napping mode.

However, if necessary, the MS may occasionally use a reserved slot or subslot for linearization purposes provided that:

- the slot or subslot has been granted to the MS by an individually addressed slot grant; and
- the MS's emission for linearization purposes conforms to the spectrum mask defined in clause 6.4.9.2.1 for emission during the useful part of the burst.

NOTE 3: For example, the MS may occasionally use this form of linearization in a reserved slot or subslot if it has been granted a large number of reserved slots on a multi-slot channel and is not able to maintain adequate linearization between the mapped CLCH-Q opportunities. Or this form of linearization could be used by a dual watching MS.

## 23.4.6 BS synchronization

When an MS moves from one carrier to another within a cell, it shall assume that the old frame and slot synchronization apply also on the new carrier. For example, at call set-up, it may immediately linearize and use granted slots or subslots using the timing of the old carrier.

Therefore, the BS shall synchronize the slot, frame and multiframe timing on all its carriers within a cell.

NOTE: This applies for all carriers within the cell. Thus the slot, frame and multiframe timing on both phase modulation carriers and QAM carriers within the cell needs to be synchronized with the slot, frame and multiframe timing on the main carrier. See clause 7 for details of the synchronization of phase modulation carriers and QAM carriers.

When the MS obeys a channel allocation for an eccentric channel, the MS may perceive a larger timing difference on the new channel relative to the old channel than when moving to a non-eccentric channel; see clauses 7.7 and 7.8. The same applies when the MS moves from an eccentric channel to another channel (for example, when the MS returns to its common control channel).

## 23.4.7 Data priority

### 23.4.7.0 Introduction

Clauses 23.4.7.1, 23.4.7.2, 23.4.7.3, 23.4.7.4, 23.4.7.5 and 23.4.7.6 shall be applicable only to MSs and BSs which support data priority.

### 23.4.7.1 General

Data priority enables the MS to indicate a priority for obtaining reserved slots when it is sending packet data. For example, this permits the BS to grant slots to an MS with high data-priority PDUs to send ahead of other MSs with lower data-priority PDUs to send on the same channel.

NOTE 1: Data priority is distinct from PDU priority. PDU priority affects the MS's queue re-ordering in the LLC and the MS's random access procedure. Data priority principally affects the BS's criteria for slot granting on a shared packet data channel, but is also used for queue re-ordering in the LLC.

The SNDCP in an MS that uses data priority either regards the "MS default data priority" as being the "network default data priority" indicated by the SwMI or may negotiate a specific MS default data priority with the SwMI (see clause 28.3.5.5). In either case, the MS default data priority is a data priority which the BS applies by default to all reservation requirements indicated by that MS on a packet data channel unless temporarily overridden by a short-term data priority requested by the MS-MAC. The higher layers inform the MS-MAC about the current MS default data priority using the TMC-CONFIGURE request primitive.

NOTE 2: The MS default data priority in the TMC-CONFIGURE request primitive may be set to one of the eight defined values of data priority (0 to 7) or may be set to "not applicable". The value "not applicable" applies if the SNDCP is not aware of the network default data priority and has not negotiated a specific MS default data priority (or if the current BS does not support data priority); it applies also when the SNDCP is not in the READY state.

Also, when the SNDCP sends each packet data PDU, it includes the data priority for that PDU within the primitive issued to the lower layers. The LLC collates the information on the data priorities for the data in its queue and issues it to the MS-MAC in the DATA-IN-BUFFER signal, indicating:

- the maximum value of the data priority for the data in the LLC queue for the specified address and endpoint identifier (set either to one of the eight defined values of data priority (0 to 7) or to value "undefined" if there is only data of undefined data priority in the LLC queue); and
- if the endpoint identifier corresponds to a  $\pi/4$ -DQPSK channel: the subdivision of that data into data priorities;
- if the endpoint identifier corresponds to a D8PSK or QAM channel: the subdivision of that data into data categories and data priorities.

NOTE 3: The LLC also indicates (using the DATA-IN-BUFFER signal) whether or not it currently expects that the next PDU to be sent with the specified address and endpoint identifier will contain packet data.

The MS-MAC sends an L2-DATA-PRIORITY message when it wishes to indicate a short-term variation on that channel which temporarily overrides the default data priority. (The MS-MAC does not send the L2-DATA-PRIORITY message until the LLC wishes to send a PDU whose data priority differs from the MS default data priority.)

The L2-DATA-PRIORITY message is a layer 2 signalling message, so the MS-MAC sends it using the data transfer service provided by the LLC at the TLE-SAP; see clause 23.1.4.

### 23.4.7.2 Content of L2-DATA-PRIORITY message

#### 23.4.7.2.1 Formats of L2-DATA-PRIORITY message

The MAC sends an L2-DATA-PRIORITY message when it wishes to indicate a short-term variation to the default data priority (see clause 23.4.7.4 for criteria for sending the L2-DATA-PRIORITY message). The L2-DATA-PRIORITY message applies to the address with which it is sent and the channel on which it is sent. It may contain either:

- 1) a single short-term data priority (the "residual data priority"); or

- 2) up to 7 data priority blocks each containing:
- a data priority (the "temporary data priority"); and
  - the expected number of slots needed to send the currently queued data at that data priority for this address and channel (as indicated in the DATA-IN-BUFFER signal from the LLC),
- followed by the "residual data priority", which applies to slots following those included in the data priority block(s).

See clause 21.2.4.1 for the description of the L2-DATA-PRIORITY PDU.

If the MS uses format 2, the data priority blocks shall be included in decreasing order of data priority.

The MS may use either format 1) or format 2) as appropriate to its capabilities or to the information in the DATA-IN-BUFFER signal.

**NOTE:** When the MS indicates its data priority requirements, it indicates only the data priority requirements for the address with which the L2-DATA-PRIORITY PDU will be sent. The ISSI and its associated ASSI are regarded as equivalent for the purposes of this procedure. Similarly, an event label and its corresponding address are regarded as equivalent for the purposes of this procedure. However, an MS is not permitted to combine any data priority requirements for its SMI with requirements for an SSI (or vice versa), and it is not permitted to combine the data priority requirements for multiple TSI families.

#### 23.4.7.2.2 Content of L2-DATA-PRIORITY message if using format 1)

If the MS-MAC uses format 1), it shall set the "residual data priority" to the maximum data priority indicated by the LLC for the appropriate address and endpoint identifier (unless the MS-MAC is sending the L2-DATA-PRIORITY message when there is only data of undefined data priority in the LLC queue, in which case the MS-MAC may set the "residual data priority" to the MS default data priority).

**NOTE:** The "residual data priority" indicates the data priority information for the data in the LLC queue (for this address on this channel), irrespective of whether the MS has already been granted some future slots.

#### 23.4.7.2.3 Content of L2-DATA-PRIORITY message if using format 2)

If the MS-MAC uses format 2) then:

- if the MS is on a  $\pi/4$ -DQPSK channel, the appropriate number of slots in each data priority block is known from the information about the amount of queued data per data priority, provided in the DATA-IN-BUFFER signal received from the LLC;
- if the MS is on a D8PSK or QAM channel, the appropriate number of slots in each data priority block shall be estimated from the information about the amount of queued data per data category and per data priority, provided in the DATA-IN-BUFFER signal received from the LLC. The expected number of slots to send the data for a particular data priority depends on both the amount of data and the modulation level (and coding rate for QAM) with which the MS-MAC currently expects to send the data. If there is data for more than one data category for this data priority, the expected modulation level (and coding rate for QAM) may be different for the different data categories; in this case, the MS-MAC shall estimate the number of slots required at each modulation level (and coding rate for QAM) and shall indicate the total in the "number of slots" element for that data priority; see also clause 23.4.9.

**NOTE 1:** The "number of slots" element indicates the number of slots that the MS needs to send the data for this data priority (for this address on this channel), irrespective of whether the MS has already been granted some future slots.

The MS-MAC may indicate a data priority requirement of one subslot, or one or more full slots (as shown in clause 21.2.4.1). The required number of slots is coded in a non-linear format. If the MS's requirement cannot be represented exactly within the defined format:

- the MS-MAC should round up to the next higher valid number of slots for data priorities above the MS default data priority;
- the MS-MAC may round down to the next lower valid number of slots for data priorities below the MS default data priority.

In most cases, the MS-MAC should choose the number of data priority blocks such that fragmentation of the message will not be needed. For example:

- if the message will be sent by random access on a  $\pi/4$ -DQPSK or D8PSK channel then:
  - if the MS has an event label, there is space for the maximum number (i.e. 7) of data priority blocks;
  - if the MS does not have an event label, there is space for up to 6 data priority blocks before fragmentation becomes necessary;
- if the message will be sent by random access on a QAM channel then:
  - if the MS has an event label, there is space for up to 4 data priority blocks before fragmentation becomes necessary;
  - if the MS does not have an event label, there is space for up to 2 data priority blocks before fragmentation becomes necessary.

**EXAMPLE:** If the MS is on a QAM channel and does not have an event label, and the LLC indicates data at data priority levels 6, 5, 4 and 3, the MAC may include data priority blocks for data priorities 6 and 5, and then set the "residual data priority" to 4 in the L2-DATA-PRIORITY message.

If the LLC is currently indicating data for N data priorities (with  $1 \leq N \leq 7$ ) and there would be space for the MS to send data priority blocks for all N data priorities without fragmentation, the MS-MAC may either:

- i) include N - 1 data priority blocks (one for each data priority except the lowest data priority in the LLC queue) and then set the "residual data priority" to the lowest of the data priorities in the LLC queue; or
- ii) include N data priority blocks (one for each data priority in the LLC queue) and then set the "residual data priority" to the MS default data priority.

**NOTE 2:** The MS designer should choose an appropriate method. (The choice of method may depend on the pattern of data and/or on whether the lowest of the data priorities in the LLC queue is more than, or less than, the MS default data priority.)

**NOTE 3:** The maximum number of data priority blocks is 7. Therefore, if the LLC is currently indicating data for all 8 data priorities, the MAC cannot use method ii).

If the MS requires more than 68 slots for a data priority, the MS-MAC may send more than one data priority block for that data priority. Otherwise it may set the "residual data priority" to the highest data priority for which more than 68 slots is required, in which case it should not include any data priority blocks for any lower data priorities.

#### 23.4.7.2.4 Sending L2-DATA-PRIORITY message

When the MS-MAC sends an L2-DATA-PRIORITY message, it shall issue the message to the LLC in a TLE-UNITDATA request primitive. The MS-MAC shall set the PDU priority level in the request primitive to the PDU priority of the highest priority message in the LLC buffer for this address and channel, as indicated in the DATA-IN-BUFFER signal from the LLC.

**NOTE 1:** Therefore the LLC will normally send the L2-DATA-PRIORITY PDU on reception of the next MAC-READY signal (delivering the PDU to the MAC using a TMA-UNITDATA request primitive).

It is recommended that the number of repetitions of the layer 2 signalling message is normally set to 0.

NOTE 2: In some cases the MS-MAC may choose to set the number of repetitions to more than 0; for example, it could choose to do so if the required data priority has increased and the MS has a large quantity of data to send with that increased data priority. However the MS designer should note that excessive repetition of the L2-DATA-PRIORITY message may reduce the MS's overall data throughput.

If the MS-MAC sends an L2-DATA-PRIORITY message, and there is a significant change in the data priority requirements before the MS-MAC receives a TLE-REPORT indication primitive reporting completion of the transfer (either successful or failed transfer), the MS-MAC may cancel the ongoing transfer using the TLE-CANCEL request primitive and then send a revised L2-DATA-PRIORITY message.

After sending an L2-DATA-PRIORITY message and receiving a TLE-REPORT indication primitive reporting first complete transmission of the message, the MS-MAC shall record the "residual data priority" in the L2-DATA-PRIORITY message and the highest "temporary data priority" in any data priority blocks. Also, if the L2-DATA-PRIORITY message contained data priority block(s), the MS-MAC shall maintain the current value of the "derived data priority". The "derived data priority" is the data priority that the MS-MAC regards as applying at the current moment for this address and channel. It is calculated by counting the number of reserved slots and subslots used for this address on this channel since the first transmission of the L2-DATA-PRIORITY message and comparing this with the numbers of slots and subslots given in the data priority block(s) as follows:

- after the first complete transmission of the L2-DATA-PRIORITY message, the MS-MAC shall set the "derived data priority" to the "temporary data priority" in the first data priority block;
- then, after each reserved slot or subslot until the "derived data priority" is set to the "residual data priority", the MS-MAC shall perform the following or equivalent check:
  - if the reserved capacity used for this address on this channel since the first complete transmission of the L2-DATA-PRIORITY message  $\geq$  capacity requested for the "derived data priority" and for any higher temporary data priorities then:
    - if there are more data priority blocks, the MS-MAC shall set the "derived data priority" to the "temporary data priority" in the next data priority block;
    - otherwise the MS-MAC shall set the "derived data priority" to the "residual data priority".

EXAMPLE: For example, if the MS included one data priority block with temporary data priority DPRI requiring 6 slots then the "derived data priority" is set to DPRI until 6 reserved slots have been used and then reverts to the residual data priority. If the MS included two data priority blocks with temporary data priorities DPRIa and DPRIb, requiring 4 slots and 6 slots respectively, then the "derived data priority" is set to DPRIa until 4 reserved slots have been used, is then set to DPRIb until a further 6 reserved slots have been used, and then reverts to the residual data priority.

### 23.4.7.3 Expiry of short-term data priority information

The data priority information included in the L2-DATA-PRIORITY message is only temporary. The SNDCP in the MS receives the value of the layer 2 data priority lifetime timer from the SwMI when it receives the network default data priority or negotiates a specific MS default data priority. The SNDCP also receives the value of the layer 2 data priority signalling delay (and the data priority random access delay factor). The higher layers inform the MS-MAC about the values of the layer 2 data priority lifetime and layer 2 data priority signalling delay timers (and the data priority random access delay factor) using the TMC-CONFIGURE request primitive.

After sending an L2-DATA-PRIORITY message and receiving a TLE-REPORT indication primitive reporting first complete transmission of the message, the MS-MAC shall start the layer 2 data priority lifetime timer T.222. It shall also start the layer 2 data priority signalling delay timer T.223.

NOTE 1: Timer T.223 is used in the criteria for sending an L2-DATA-PRIORITY message (see clause 23.4.7.4).

The MS-MAC shall assume that the information sent in the L2-DATA-PRIORITY message applies until one of the following occurs:

- a) a time T.222 has elapsed since the MS-MAC received the TLE-REPORT indication primitive reporting first complete transmission of the message; or
- b) the MS-MAC initiates the random access procedure for this address on this channel and has transmitted a first random access request; or
- c) the MS-MAC sends another L2-DATA-PRIORITY message for this address on this channel and has received a TLE-REPORT indication primitive reporting that the message has been completely transmitted once.

In case a), the MS-MAC shall assume that the MS's current data priority for this address and channel is the MS default data priority.

In case b), after transmitting the first random access request, the MS-MAC shall assume that its current data priority for this address and channel is the MS default data priority. (If the random access request carried an L2-DATA-PRIORITY message then the data priority information in that L2-DATA-PRIORITY message shall apply, and timers T.222 and T.223 shall be started, when the MS-MAC receives the TLE-REPORT indication primitive from the LLC reporting first complete transmission of the message as in case c).)

In case c), when the MS-MAC receives the TLE-REPORT indication primitive reporting first complete transmission of the new L2-DATA-PRIORITY message, it shall assume that the information sent in the new L2-DATA-PRIORITY message applies and shall start the layer 2 data priority lifetime timer T.222 and the layer 2 data priority signalling delay timer T.223.

NOTE 2: If the message is not completely transmitted at least once, the MS-MAC assumes that the information sent in the previous L2-DATA-PRIORITY message applies until one of criteria a), b) or c) occurs.

#### 23.4.7.4 Criteria for sending L2-DATA-PRIORITY message

The MS-MAC shall not send the L2-DATA-PRIORITY message if:

- it has not received a SYSINFO, SYSINFO-Q or SYSINFO-DA PDU from the BS indicating that the BS supports data priority (using the "extended services broadcast" element in the SYSINFO or SYSINFO-Q PDU or the "extended DA services broadcast" element in the SYSINFO-DA PDU); or
- the MS default data priority last provided by the higher layers in the TMC-CONFIGURE request primitive was set to "not applicable".

The MS-MAC should not send the L2-DATA-PRIORITY message if it has already been granted capacity sufficient and suitable for its current reserved access requirements for this address on this channel.

NOTE 1: On a  $\pi/4$ -DQPSK or D8PSK channel, or if the MS does not currently have any schedules in operation, the MS-MAC should not send the L2-DATA-PRIORITY message if it has already been granted capacity sufficient for its current reserved access requirements for this address on this channel. On a QAM channel, if the MS has schedule(s) in operation and also has unscheduled data to send, and has been granted capacity by multiple slot granting, then it may choose to send the L2-DATA-PRIORITY message if the granted capacity matches only its expected future scheduled access requirements.

Also, if the DATA-IN-BUFFER signal indicates that the next PDU that the LLC expects to send for this address on this channel does not contain packet data, the MS-MAC should not send the L2-DATA-PRIORITY message at this time (see note 2) unless:

- the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is data priority 7; and
- the amount of data indicated in the DATA-IN-BUFFER signal for data priority 7 would not fit within the next MAC block that the MS will be transmitting on this channel (either within the next granted slot or subslot, or within the random access request if appropriate); and
- the MS has not already been granted capacity sufficient and suitable for the amount of data with data priority 7.

NOTE 2: The MS-MAC may send the L2-DATA-PRIORITY message if both PDUs would fit within the next MAC block that the MS will be transmitting on this channel. Also, if the MS-MAC has issued an L2-LINK-FEEDBACK-INFO message to the LLC, and the MS supports the combined L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU (see clause 22.3.1.7.3), the MS-MAC may send an L2-DATA-PRIORITY message containing only a "residual data priority".

Subject to the above constraints, the MS-MAC may send the L2-DATA-PRIORITY message if any of the following criteria are satisfied:

- the MS default data priority currently applies for this address on this channel (i.e. the MS-MAC has not sent an L2-DATA-PRIORITY message or timer T.222 has expired or the MS-MAC has transmitted a random access request since the last L2-DATA-PRIORITY message), or the MS is initiating the random access procedure, and:
  - the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is not equal to the MS default data priority (see note 3); or
  - if the MS supports format 2): the DATA-IN-BUFFER signal indicates data for this address and channel with a defined data priority not equal to the MS default data priority (see note 4);

NOTE 3: When the maximum data priority indicated in the DATA-IN-BUFFER signal is a defined value less than the MS default data priority, the MS-MAC may decide not to send the L2-DATA-PRIORITY message if there is only a small amount of data to send at less than the MS default data priority; this may be preferable particularly if the MS is not initiating the random access procedure.

NOTE 4: In the case indicated, transmission of the L2-DATA-PRIORITY message is permitted if the maximum data priority indicated in the DATA-IN-BUFFER signal is equal to the MS default data priority but there is data with data priority lower than the MS default data priority. Alternatively, the MS may wait until the maximum data priority indicated in the DATA-IN-BUFFER signal is not equal to the MS default data priority before sending the L2-DATA-PRIORITY message; this may be preferable particularly if the MS is not initiating the random access procedure.

- information sent in the last L2-DATA-PRIORITY message for this address on this channel still applies and any of the following criteria a), b) or c) are satisfied:
  - a) the last L2-DATA-PRIORITY message contained only a "residual data priority" and the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the "residual data priority"; or
  - b) the last L2-DATA-PRIORITY message contained data priority block(s) and:
    - i) the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the highest "temporary data priority" in the data priority block(s) in the last L2-DATA-PRIORITY message and is greater than the current "derived data priority"; or
    - ii) the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the current "derived data priority"; or
    - iii) as an alternative option to ii), the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel will be greater than the "derived data priority" that will apply after use of the next reserved slot or subslot;
  - c) a time T.223 has elapsed since the MS-MAC received the TLE-REPORT indication primitive reporting first complete transmission of the message and either:
    - there has been a change in the data priority information since the last L2-DATA-PRIORITY message (see below); or
    - the last L2-DATA-PRIORITY message was not sent by successful random access; however, the MS-MAC shall not send the same or equivalent information more than a total of N.223 times (see note 7).

NOTE 5: In cases a) and b), the MS-MAC should not send the L2-DATA-PRIORITY message if it has already been granted capacity sufficient and suitable for its reserved access requirements for the data with data priority greater than the "residual data priority" or highest "temporary data priority" or "derived data priority" as appropriate in the specified criteria.

NOTE 6: The MS may send the L2-DATA-PRIORITY message immediately if criterion a) or criterion b) i) is satisfied. The MS is also permitted to send the L2-DATA-PRIORITY message immediately if criterion b)ii) or b)iii) is satisfied. However the MS designer should note that care needs to be taken to avoid excessive use of the L2-DATA-PRIORITY message. Excessive use of the L2-DATA-PRIORITY message (in an attempt to track fluctuating data priority requirements too closely) may reduce the MS's overall data throughput.

NOTE 7: If an L2-DATA-PRIORITY message was sent by stealing or reserved access, or if the transfer failed, the MS-MAC may send another L2-DATA-PRIORITY message after expiry of timer T.223 (and possibly again after the next expiry of timer T.223 if the L2-DATA-PRIORITY message was again sent by stealing or reserved access) - within the limit defined by N.223; see point c) above. This may apply particularly if the number of repetitions of the layer 2 signalling message was 0. However, the MS-MAC should not continually send the same or equivalent information after each expiry of timer T.223 since this may reduce the MS's overall data throughput. Also, if the number of repetitions of the layer 2 signalling message was not 0, the MS-MAC should reduce the value of N.223 accordingly.

In case c) above, the MS designer should choose criteria for the MS-MAC to send the L2-DATA-PRIORITY message after expiry of the layer 2 data priority signalling delay timer T.223. As always, the MS-MAC may send the L2-DATA-PRIORITY message if criterion a) or b) is satisfied. Additionally, the MS-MAC may regard the following or equivalent cases as constituting a change in the data priority information since the last L2-DATA-PRIORITY message such that an L2-DATA-PRIORITY message may be sent after expiry of timer T.223:

- the last L2-DATA-PRIORITY message contained data priority block(s) and the MS-MAC deduces from the information in the DATA-IN-BUFFER signal for this address and channel that the LLC now has a significant amount of new data to send for the data priorities appropriate to those data priority block(s); or
- the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is less than:
  - the "residual data priority", if the last L2-DATA-PRIORITY message contained only a "residual data priority"; or
  - the current "derived data priority", if the last L2-DATA-PRIORITY message contained data priority block(s).

In the second two cases, the MS-MAC may decide not to send the L2-DATA-PRIORITY message if there is only a small amount of data to be sent with the lower data priority.

NOTE 8: The MS designer should note that care needs to be taken to avoid excessive use of the L2-DATA-PRIORITY message, while at the same time avoiding delays in receiving high data-priority capacity when it is required and avoiding receiving too much capacity with higher data priority than needed. Excessive use of the L2-DATA-PRIORITY message (in an attempt to track fluctuating data priority requirements too closely) may reduce the MS's overall data throughput; this applies particularly if the MS will send the L2-DATA-PRIORITY message using reserved access.

## 23.4.7.5 Reverting to random access if MS supports data priority

### 23.4.7.5.1 General

As defined in clause 23.5.1.4.3, the MS-MAC may initiate the random access procedure immediately if the MS has individually addressed unscheduled signalling messages to send, and the MS-MAC does not currently have any capacity granted for this address on this control channel, and either:

- a) it has not already sent a PDU indicating a reservation requirement for this address on this control channel; or
- b) the DATA-IN-BUFFER signal from the LLC indicates that a new emergency unscheduled message has been received from layer 3.

Also, the MS-MAC may initiate the random access procedure if the MS has unscheduled signalling messages to send, and the MS-MAC has sent a PDU indicating a reservation requirement for this address on this control channel and does not currently have any capacity granted for this address on this control channel, and the timing criteria in clause 23.5.2.4.1 are satisfied.

NOTE 1: The MS-MAC may also initiate the random access procedure if the MS has scheduled signalling messages to send for this address on this control channel and the criteria in clause 23.5.2.4.2 are satisfied.

The procedure in clause 23.5.2.4.1 requires the MS-MAC to continue to wait when it receives a "basic slot granting" element for this address on this channel containing the instruction to "Wait for another slot grant" (except in case of emergency); the BS may send the instruction to "Wait for another slot grant" repeatedly to the MS, in which case the MS-MAC continues to wait. This procedure generally applies also when the MS is sending packet data. However, if the MS supports data priority (and the SNDCP is in the READY state), the MS-MAC is permitted to initiate the random access procedure if the criteria in clause 23.4.7.5.2 or 23.4.7.5.3 are satisfied - even though the criteria in clause 23.5.2.4.1 may not be satisfied.

NOTE 2: If the criteria in clause 23.5.2.4.1 are satisfied before the criteria in clause 23.4.7.5.2 or 23.4.7.5.3 are satisfied, the MS-MAC may initiate the random access procedure in the usual way.

The procedure in clause 23.4.7.5.2 gives criteria based on an increase in the MS's data priority requirements. This procedure may allow the MS-MAC to initiate the random access procedure earlier than in clause 23.5.2.4.1 in order to indicate its increased data priority requirements (for example, when the BS has sent the instruction to "Wait for another slot grant" because it is granting slots to other MS(s) with higher data priority than the MS indicated in its last L2-DATA-PRIORITY message).

The procedure in clause 23.4.7.5.3 gives criteria if the next message that the MS expects to send does not contain packet data, for example, if the next message is an acknowledged basic link message or link adaptation feedback message. An uplink message that does not contain packet data has undefined data priority (except optionally for PDU priority 7), so it takes the data priority of any packet data behind it in the LLC queue by default. However, the procedure in clause 23.4.7.5.3 may allow the MS-MAC to initiate the random access procedure earlier than in clause 23.5.2.4.1 in order to send the non-packet-data message (for example, when the BS has sent the instruction to "Wait for another slot grant" because it is granting slots to other MS(s) with higher data priority than the MS indicated in its last L2-DATA-PRIORITY message).

#### 23.4.7.5.2 Reverting to random access to send L2-DATA-PRIORITY message

If the following criteria are all satisfied then the MS-MAC may initiate the random access procedure (see clause 23.5.1):

- a) the MS-MAC has received a SYSINFO, SYSINFO-Q or SYSINFO-DA PDU from the BS indicating that the BS supports data priority;
- b) the MS default data priority last provided by the higher layers in the TMC-CONFIGURE request primitive was set to a defined value (i.e. was not set to "not applicable");
- c) the MS-MAC has sent a PDU (MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU or MAC-END) indicating a reservation requirement for this address on this control channel;
- d) the MS-MAC does not currently have any capacity granted for this address on this control channel;
- e) the MS default data priority currently applies for this address on this channel and the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the MS default data priority; or

information sent in the last L2-DATA-PRIORITY message for this address on this channel still applies and either:

- i) the last L2-DATA-PRIORITY message contained only a "residual data priority" and the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the "residual data priority"; or

- ii) the last L2-DATA-PRIORITY message contained data priority block(s) and:
- the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the highest "temporary data priority" in the data priority block(s) in the last L2-DATA-PRIORITY message and is greater than the current "derived data priority"; or
  - the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is a defined value and is greater than the current "derived data priority";
- f) a time T has elapsed since the MS-MAC last sent a PDU on this control channel for this address (i.e. either a MAC-ACCESS, MAC-DATA or MAC-U-BLCK PDU with this address or a MAC-FRAG, MAC-END or MAC-END-HU PDU relating to this address), where T is defined as follows:
- if  $DF = 0$  then  $T = T.206$ ;
  - if  $DF > 0$  then  $T = (8 - MDP) \times DF \times T.206$ ,

where:

- MDP is the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel;
- DF is the current value of the data priority random access delay factor (received from the SwMI at SMDCP level and provided to the MS-MAC using the TMC-CONFIGURE request primitive);
- T.206 is the value of the reserved access waiting time-out (see annex B); and
- T is measured in terms of downlink signalling frames for this control channel (as for timer T.206).

NOTE 1: When appropriate, this procedure allows the MS to revert to random access after time T has elapsed even if the MS-MAC has received a "basic slot granting" element for this address on this control channel containing the instruction to "Wait for another slot grant". Therefore, in the cases listed in criterion e), this procedure may permit the MS to revert to random access in order to send an L2-DATA-PRIORITY message even though the criteria in clause 23.5.2.4.1 may not be satisfied.

NOTE 2: The MS is permitted to revert to random access to send the L2-DATA-PRIORITY message after time T has elapsed if any of the criteria in e) are satisfied. However the MS designer should note that excessive sending of the L2-DATA-PRIORITY message by random access (in an attempt to track fluctuating data priority requirements too closely) may reduce the performance of the random access channel.

If the MS-MAC decides to initiate the random access procedure and wishes to send an L2-DATA-PRIORITY message, it should issue the L2-DATA-PRIORITY message to the LLC in a TLE-UNITDATA request primitive and then issue the MAC-READY signal.

NOTE 3: In an implementation, the MAC should not issue the MAC-READY signal until the LLC has had time to process the TLE-UNITDATA request primitive.

If the MS-MAC decides to initiate the random access procedure based on the above criteria being satisfied, but it does not wish to send an L2-DATA-PRIORITY message, it should issue the MAC-READY signal to the LLC since there may be a PDU in the LLC queue that can be sent within the MAC-ACCESS PDU. For example, this may apply if the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is the MS default data priority - since the action of sending a random access request implicitly sets the MS's current data priority for this address and channel to the MS default data priority (see clause 23.4.7.3). Or the MS-MAC may decide not to send the L2-DATA-PRIORITY message at this time if the amount of data indicated in the DATA-IN-BUFFER signal for the maximum data priority for this address and channel could be sent within the random access request.

The random access request shall be sent on SCH/HU (for a  $\pi/4$ -DQPSK or D8PSK channel) or on SCH-Q/RA (for a QAM channel) using the MAC-ACCESS PDU, containing a TM-SDU if appropriate. If the MS has any further signalling ready to send for this address on this control channel, the MS-MAC shall include a request for reserved capacity ("reservation requirement" element) in the MAC-ACCESS PDU.

NOTE 4: If the MS was in the process of sending a fragmented message at the time when it decides to initiate the random access procedure, it should discard the partially sent TM-SDU. (Alternatively the MS may choose not to initiate the random access procedure in this case.)

### 23.4.7.5.3 Reverting to random access to send non-packet-data message

If the following criteria are all satisfied then the MS-MAC may initiate the random access procedure (see clause 23.5.1):

- a) the MS-MAC has received a SYSINFO, SYSINFO-Q or SYSINFO-DA PDU from the BS indicating that the BS supports data priority;
- b) the MS default data priority last provided by the higher layers in the TMC-CONFIGURE request primitive was set to a defined value (i.e. was not set to "not applicable");
- c) the MS-MAC has sent a PDU (MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU or MAC-END) indicating a reservation requirement for this address on this control channel;
- d) the MS-MAC does not currently have any capacity granted for this address on this control channel;
- e) the DATA-IN-BUFFER signal indicates that the next PDU that the LLC expects to send for this address on this control channel does not contain packet data;
- f) a time T has elapsed since the MS-MAC last sent a PDU on this control channel for this address (i.e. either a MAC-ACCESS, MAC-DATA or MAC-U-BLCK PDU with this address or a MAC-FRAG, MAC-END or MAC-END-HU PDU relating to this address), where T is defined as follows:
  - if  $DF = 0$  then  $T = T.206$ ;
  - if  $DF > 0$  then  $T = 2 \times DF \times T.206$ ,

where:

- DF is the current value of the data priority random access delay factor (received from the SwMI at SNDCP level and provided to the MS-MAC using the TMC-CONFIGURE request primitive);
- T.206 is the value of the reserved access waiting time-out (see annex B); and
- T is measured in terms of downlink signalling frames for this control channel (as for timer T.206).

If the MS-MAC decides to initiate the random access procedure based on the above criteria being satisfied, it should not send an L2-DATA-PRIORITY message at this time (unless the maximum data priority indicated in the DATA-IN-BUFFER signal for this address and channel is data priority 7 and the amount of data indicated in the DATA-IN-BUFFER signal for data priority 7 would not fit within the random access request).

NOTE 1: If the MS-MAC has issued an L2-LINK-FEEDBACK-INFO message to the LLC, and the MS supports the combined L2-LINK-FEEDBACK-INFO-AND-RESIDUAL-DATA-PRIORITY PDU (see clause 22.3.1.7.3), the MS-MAC may send an L2-DATA-PRIORITY message containing only a "residual data priority".

The random access request shall be sent on SCH/HU (for a  $\pi/4$ -DQPSK or D8PSK channel) or on SCH-Q/RA (for a QAM channel) using the MAC-ACCESS PDU, containing a TM-SDU if appropriate. If the MS has any further signalling ready to send for this address on this control channel, the MS-MAC shall include a request for reserved capacity ("reservation requirement" element) in the MAC-ACCESS PDU.

NOTE 2: If the MS was in the process of sending a fragmented message at the time when it decides to initiate the random access procedure, it should discard the partially sent TM-SDU. (Alternatively the MS may choose not to initiate the random access procedure in this case.)

## 23.4.7.6 BS procedures for data priority

### 23.4.7.6.1 Packet data on uplink

If the BS supports data priority, it should use any:

- information about the default data priority; and
- short-term data priority information received in L2-DATA-PRIORITY messages,

for the MSs on a shared channel used for packet data in deciding when to grant slots to those MSs. The BS may also use uplink fragmentation as a criterion in deciding when to grant slots to MSs (see note). The methods used by the BS for scheduling of the uplink channel are outside the scope of the present document.

**NOTE:** If an MS on a packet data channel has a message to send that does not contain packet data (for example, an acknowledged basic link message), it may be permitted to use random access to send the message; see clauses 23.4.7.5.3 and 23.5.1.4.3. An uplink message that does not contain packet data has undefined data priority (except optionally for PDU priority 7) and may require fragmentation. The BS may choose to give high priority to fragmented messages when granting slots.

The BS should assume that the default data priority applies for an MS unless it has received an L2-DATA-PRIORITY message from that MS.

After receiving an L2-DATA-PRIORITY message from an MS, the BS should assume that the information sent in the L2-DATA-PRIORITY message applies while that MS is sending packet data on that channel, until one of the following occurs:

- a) a time corresponding to the layer 2 data priority lifetime timer for that MS has elapsed since receipt of the L2-DATA-PRIORITY message; or
- b) the BS receives a MAC-ACCESS PDU from that MS, sent by random access on that channel; or
- c) the BS receives another L2-DATA-PRIORITY message from that MS on that channel.

In case a), the BS should assume that the default data priority applies for that MS until it receives another L2-DATA-PRIORITY message from that MS.

In case b), if the MAC-ACCESS PDU contained an L2-DATA-PRIORITY message, the BS should assume that the information sent in the L2-DATA-PRIORITY message applies as in case c); otherwise the BS should assume that the default data priority applies for that MS until it receives another L2-DATA-PRIORITY message from that MS.

In case c), the BS should assume that the information sent in the new L2-DATA-PRIORITY message applies until one of cases a), b) or c) occurs as above.

The "data priority details" element sent by the BS's SNDCP entity in some SNDCP PDUs contains the values of the layer 2 data priority lifetime (timer T.222) and the layer 2 data priority signalling delay (timer T.223) to be used by the addressed MS(s). The "data priority details" element also allows control of how soon the MS(s) may revert to random access to send the L2-DATA-PRIORITY message or a message that does not contain packet data, by using the data priority random access delay factor (see clause 23.4.7.5). The methods used by the BS to choose the values of these parameters are outside the scope of the present document.

### 23.4.7.6.2 Packet data on downlink

The methods used by the BS for scheduling of data packets on the downlink channel are outside the scope of the present document.

## 23.4.8 Napping

### 23.4.8.1 General

As described in clause 23.7.6, the MS may use energy economy mode when on its common control channel (i.e. the MCCH or MCCH-Q, or the appropriate  $\pi/4$ -DQPSK or QAM common SCCH) if it has negotiated an energy economy group by an MM message exchange. Or, as described in clause 23.7.8, a DA MS may use the part-time reception procedure (if permitted by the BS) when on a multi-slot MCCH-Q.

The napping procedure is an independent procedure which may apply when the MS is on an assigned channel. It may provide the MS with some opportunities for neighbour cell monitoring, irregular channel monitoring, main carrier monitoring and/or background scanning, even when the MS is on a multi-slot assigned channel; also it may allow some battery economy in the MS. However it generally requires more reception than when the MS is using energy economy mode.

NOTE 1: The napping procedure does not apply when the MS is in common mode on its common control channel.

NOTE 2: The napping procedure applies for MSs that are in assigned mode, having accepted a channel allocation for an assigned channel. In some cases other MSs may be in common mode on the same physical channel(s), in which case energy economy mode (or dual watch mode or part-time reception mode) may apply for those other MSs. For example, for DA, this may occur if the BS assigns the physical channel(s) used for the MCCH-Q as a QAM assigned SCCH while still maintaining the MCCH-Q for MSs in common control mode.

When the BS sends an augmented channel allocation for an assigned channel, it indicates whether use of the napping procedure is permitted on the assigned channel. If use of the napping procedure is permitted, the BS normally includes the appropriate napping information for use on the assigned channel. The napping information comprises:

- the "napping reception timeslots" i.e. a timeslot bit map indicating the downlink slot or slots that the MS is required to receive in the napping reception frames when the MS is in napping mode (but limited to the slots appropriate to the downlink assigned channel);
- the "napping reception frames" when in napping mode, specified as either:
  - all downlink TDMA frames; or
  - every two TDMA frames (so that the MS is only required to receive in either odd-numbered or even-numbered TDMA frames); or
  - every three TDMA frames (so that the MS is only required to receive in every third TDMA frame);
- the value of the napping timer T.226; and
- a flag indicating whether the MS may use reduced reception in frame 18 when not in napping mode.

Alternatively, the BS may indicate that any napping information for the current channel (i.e. the channel on which the channel allocation was received) may be used on the assigned channel. For example, this may apply in the case of a channel replacement on a group address.

The napping method allows the MS to use napping mode when it has not sent or received a message recently i.e. during long gaps between transmissions (based on inactivity timer T.226).

Also the BS may instruct the MS dynamically that the MS may return to napping mode immediately (see note 3). This dynamic instruction may be used to allow the MS to use napping mode temporarily during short gaps in transmission. It may also be used to allow a fast return to napping mode at the end of the current data. The BS informs the MS that it may return to napping mode immediately by setting the "immediate napping permission flag" element to 1 (see note 3). This element is included in:

- MAC-RESOURCE and MAC-END PDUs sent using  $\pi/8$ -D8PSK or QAM modulation; and
- MAC-D-BLCK PDUs.

When the MS receives a MAC-RESOURCE or MAC-END PDU sent using  $\pi/4$ -DQPSK modulation, it regards the PDU as not giving immediate napping permission.

NOTE 3: The MS does not return to napping mode on receipt of a PDU with the "immediate napping permission flag" set to 1 if it has received a PDU on a different address not giving immediate napping permission.

### 23.4.8.2 MS criteria for napping

If the MS supports napping, and is on an assigned channel on which use of the napping procedure is permitted (i.e. if the channel was allocated with an augmented channel allocation with "napping status" element set to 01<sub>2</sub> or 10<sub>2</sub>), the MS-MAC shall maintain a record of whether it is currently either:

- required to be in full reception mode; or
- permitted to be in napping mode;

on that assigned channel. This is specified in terms of whether each of its valid addresses (individual and group addresses) are currently "eligible for napping" or "ineligible for napping" on the assigned channel. As defined below, the MS-MAC is not permitted to use napping mode unless all its valid addresses are currently "eligible for napping" on this channel (plus some additional criteria).

EXAMPLE: On receipt of a PDU for any of the MS's valid addresses, and that does not give immediate napping permission (i.e. that either does not contain the "immediate napping permission flag" or contains the "immediate napping permission flag" set to 0), the MS is required to use full reception mode. A PDU giving immediate napping permission overrides a previous instruction not to nap received on the same address; however it does not override a previous instruction not to nap received on a different address.

NOTE 1: The ISSI and its associated ASSI are regarded as equivalent for the purposes of this procedure. Similarly, an event label and its corresponding address are regarded as equivalent for the purposes of this procedure.

The MS-MAC shall regard all its addresses as "ineligible for napping" on the assigned channel when it first moves to the assigned channel. The MS-MAC shall then maintain a record of whether an address is currently "eligible for napping" or "ineligible for napping" on the assigned channel as follows:

- a) If the MS-MAC receives a MAC-RESOURCE PDU on this channel and containing that address then:
  - if the MAC-RESOURCE PDU either does not contain the "immediate napping permission flag" or contains the "immediate napping permission flag" set to 0, the MS-MAC shall regard that address as currently "ineligible for napping";
  - if the MAC-RESOURCE PDU contains the "immediate napping permission flag" set to 1, the MS-MAC may regard that address as currently "eligible for napping".
- b) If the MS-MAC receives a MAC-END PDU on this channel and relating to that address then:
  - if the MAC-END PDU either does not contain the "immediate napping permission flag" or contains the "immediate napping permission flag" set to 0, the MS-MAC shall regard that address as currently "ineligible for napping";
  - if the MAC-END PDU contains the "immediate napping permission flag" set to 1, the MS-MAC may regard that address as currently "eligible for napping".
- c) If the MS-MAC receives a MAC-D-BLCK PDU on this channel and containing that address then:
  - if the MAC-D-BLCK PDU contains the "immediate napping permission flag" set to 0, the MS-MAC shall regard that address as currently "ineligible for napping";
  - if the MAC-D-BLCK PDU contains the "immediate napping permission flag" set to 1, the MS-MAC may regard that address as currently "eligible for napping".
- d) If a time T.226 has elapsed since the MS moved to the channel and the MS-MAC has not sent or received a PDU on this channel using that address, and the MS does not have any reserved capacity on this channel granted for that address, then the MS-MAC may regard that address as currently "eligible for napping".
- e) If a time T.226 has elapsed since the MS-MAC last sent or received a PDU on this channel using that address or relating to that address, and the MS does not have any reserved capacity on this channel granted for that address, then the MS-MAC may regard that address as currently "eligible for napping".

NOTE 2: In cases a), b) and c), if the "immediate napping permission flag" is set to 1, the MS-MAC may regard the address as "eligible for napping" irrespective of whether the MS has been granted reserved capacity for that address.

The MS-MAC shall enter full reception mode when it first moves to the assigned channel.

The MS-MAC shall enter (or remain in) full reception mode on the assigned channel when any of the following events occurs:

- any of its valid addresses become "ineligible for napping" on this channel; or
- it initiates the random access procedure on this channel; or
- it receives a MAC-RESOURCE PDU on this channel containing one of its addresses or event labels, and containing "Length indication" set to 111111<sub>2</sub> (indicating the start of fragmentation); or
- it enters traffic mode on this channel for transmission and/or reception (see clause 23.8).

When the MS-MAC is in full reception mode on the assigned channel, it may enter napping mode on the assigned channel if:

- all its valid addresses are currently "eligible for napping" on this channel; and
- it is not currently making a random access attempt on this channel (see note 3); and
- it is not currently performing reconstruction on this channel of a downlink TM-SDU for any of its addresses or event labels (see note 4); and
- it is not in traffic mode for transmission or reception on this channel (see note 5).

NOTE 3: At the end of a random access attempt (i.e. when the MS receives a response from the BS or abandons the random access attempt), the MS may check whether it may enter napping mode based on the other criteria. For example, if the BS response message gives immediate napping permission, the response message makes that address currently eligible for napping; if the BS response message does not give immediate napping permission, that address is currently ineligible for napping.

NOTE 4: At the end of a reconstruction (i.e. when the MS receives the MAC-END PDU or the reconstruction procedure fails), the MS may check whether it may enter napping mode based on the other criteria.

NOTE 5: The MS may check whether it may enter napping mode based on the other criteria when it goes out of traffic mode.

NOTE 6: If the MS is in napping mode on a channel assigned for a circuit mode call, and it receives an ACCESS-ASSIGN PDU in frames 1 to 17 in a slot appropriate to the downlink assigned channel, containing Header  $\neq 00_2$  and containing the correct downlink traffic usage marker for this MS, the MS may choose to revert to full reception mode temporarily if it wishes to use "N.213 permission method" criterion for entering traffic mode for reception of traffic (see clause 23.8.2.3.2).

### 23.4.8.3 MS reception requirements

#### 23.4.8.3.1 Generation of napping reception pattern

The "napping reception timeslots" element is a four-bit bit map, even when the allocated channel is a one-slot, two-slot or three-slot channel. In order to allow the BS flexibility to instruct the MS that the current napping information may be used on another allocated channel (for example, in the case of a channel replacement), the "napping reception timeslots" bit map may contain a bit set to 1 for timeslot(s) that are not appropriate to the downlink assigned channel as defined by element "timeslot assigned". This does not indicate that the MS is required to receive those slots.

Therefore, when the MS moves to a assigned channel on which use of the napping procedure is permitted (i.e. when it obeys an augmented channel allocation with "napping status" element set to  $01_2$  or  $10_2$ ), the MS-MAC shall derive a "napping reception pattern" for that channel i.e. a four-bit timeslot bit map indicating the downlink slot or slots that the MS-MAC is required to receive in the napping reception frames when it is in napping mode. The MS-MAC shall derive the "napping reception pattern" from the "timeslot assigned" element for the assigned channel and from the appropriate "napping reception timeslots" element; the latter is:

- for "napping status" =  $01_2$ , the "napping reception timeslots" element in the "napping information" element in the channel allocation; or
- for "napping status" =  $10_2$ , the "napping reception timeslots" element appropriate on the channel on which the channel allocation was received.

For each of the four bits in the "timeslot assigned" and "napping reception timeslots" bit maps:

- if that bit is set to 1 in both the "timeslot assigned" and "napping reception timeslots" bit maps, then the MS-MAC shall set the corresponding bit in the "napping reception pattern" bit map to 1;
- otherwise the MS-MAC shall set the corresponding bit in the "napping reception pattern" bit map to 0.

If the resulting "napping reception pattern" is  $0000_2$  (i.e. no match between the "timeslot assigned" and "napping reception timeslots" bit maps), the MS-MAC shall set the "napping reception pattern" to the value of the "timeslot assigned" element.

#### 23.4.8.3.2 Reception requirements when MS is in napping mode

When the MS-MAC is in napping mode on an assigned channel, it shall attempt to receive and decode at least the downlink slots indicated by the "napping reception pattern" in at least the TDMA frames indicated by the "napping reception frames" element for that assigned channel (within the constraints of the cell reselection procedures, and linearization and transmission requirements). If the MS is not able to attempt to receive and decode at least one of the downlink slots indicated by the "napping reception pattern" in a TDMA frame indicated by the "napping reception frames" element because of linearization or transmission requirements then, in that TDMA frame, the MS shall attempt to receive and decode any downlink slots of the assigned channel that it is capable of receiving.

Additionally, when the MS-MAC is in napping mode on an assigned channel and:

- MAC timer T.202 is running on this channel; and/or
- MAC timer T.206 is running on this channel; and/or
- the LLC has indicated (using the "LLC timer status" parameter in the TMC-CONFIGURE request primitive) that any of its timers measured in downlink signalling frames are currently running on this channel;

the MS shall attempt to receive and decode at least the downlink slots indicated by the "napping reception pattern" in all TDMA frames (within the constraints of the cell reselection procedures, and linearization and transmission requirements). If the MS is not able to attempt to receive and decode at least one of the downlink slots indicated by the "napping reception pattern" in a TDMA frame because of linearization or transmission requirements then, in that TDMA frame, the MS shall attempt to receive and decode any downlink slots of the assigned channel that it is capable of receiving.

NOTE 1: The LLC timers that are measured in downlink signalling frames are timers T.251, T.252, T.261, T.263 and T.265; see annex A.

NOTE 2: The procedure requiring reception in all TDMA frames (not just in the napping reception frames) when T.202 or T.206 or one of these LLC timers is running is defined so that the MS and BS should count the downlink signalling frames in the same way, even if the BS perceives that the MS may be napping when the MS is actually in full reception mode (for example, because another address is ineligible for napping or because the MS was not able to decode a PDU giving immediate napping permission).

NOTE 3: In an implementation, the MS may choose to regard the "napping reception frames" as always requiring reception in all TDMA frames. This reduces the napping opportunities when the BS has permitted reception every two or three TDMA frames in napping mode, but would mean that the same procedure applies in napping mode irrespective of whether T.202 or T.206 or the LLC timers are running.

NOTE 4: The setting of the "reduced reception in frame 18 flag" for the assigned channel affects the reception requirements when the MS is in full reception mode. It does not affect the reception requirements when the MS is in napping mode.

### 23.4.8.3.3 Reception requirements when MS is in full reception mode

When the MS-MAC is in full reception mode on an assigned channel on which use of the napping procedure is permitted, the MS reception requirements may vary depending on the value of the "reduced reception in frame 18 flag" for that assigned channel. If the "reduced reception in frame 18 flag" was set to 1, the MS is usually permitted to use the "napping reception pattern" in frame 18 instead of receiving all downlink slots of the assigned channel (as indicated by the "timeslot assigned" element in the channel allocation).

If the MS is in full reception mode on an assigned channel and is not in traffic mode for transmission or reception on this channel then:

- the MS shall attempt to receive and decode all downlink slots of the assigned channel in frames 1 to 17 (within the constraints of the cell reselection procedures, and linearization and transmission requirements);
- if the "reduced reception in frame 18 flag" was set to 0 indicating that reduced reception in frame 18 is not permitted, or the MS-MAC is currently performing reconstruction on this channel of a downlink TM-SDU for any of its addresses or event labels, then the MS shall attempt to receive and decode all downlink slots of the assigned channel in frame 18 (within the constraints of the cell reselection procedures, and linearization and transmission requirements);
- if the "reduced reception in frame 18 flag" was set to 1 indicating that reduced reception in frame 18 is permitted, and the MS-MAC is not currently performing reconstruction on this channel of a downlink TM-SDU for any of its addresses or event labels, then the MS shall attempt to receive and decode at least the downlink slots indicated by the "napping reception pattern" in frame 18 (within the constraints of the cell reselection procedures, and linearization and transmission requirements); if the MS is not able to attempt to receive and decode at least one of the downlink slots indicated by the "napping reception pattern" in a frame 18 because of linearization or transmission requirements then, in that frame 18, the MS shall attempt to receive and decode any downlink slots of the assigned channel that it is capable of receiving.

If the MS is in traffic mode for transmission or reception on this channel, the requirements for reception of the downlink channel shall be as specified in clauses 23.3.1.3 and 23.3.1.4.

### 23.4.8.4 MS use of napping status element

When the MS moves to an assigned channel allocated with an augmented channel allocation, the "napping status" element indicates whether use of the napping procedure is permitted on the allocated channel. If "napping status" = 00<sub>2</sub> (or for a non-augmented channel allocation), the MS shall assume that use of the napping procedure is not permitted on the allocated channel. If "napping status" = 01<sub>2</sub> or 10<sub>2</sub>, the MS may assume that use of the napping procedure is permitted on the allocated channel.

If "napping status" = 01<sub>2</sub>, the appropriate napping information for use on the allocated channel is included in the channel allocation.

Alternatively, the "napping status" element may be set to 10<sub>2</sub>, indicating that the MS may regard any napping information appropriate on the current channel (i.e. the channel on which the channel allocation was received) as being appropriate also on the allocated channel. Thus:

- the MS may regard the "napping reception frames", "napping timer T.226" and "reduced reception in frame 18 flag" from the current napping information as being appropriate on the allocated channel;
- the MS may also regard the "napping reception timeslots" from the current napping information as being appropriate on the allocated channel, in which case it shall use that information, together with the "timeslot assigned" element for the allocated channel, in order to derive the "napping reception pattern" for the allocated channel (see clause 23.4.8.3.1).

### 23.4.8.5 Independent allocation of uplink and downlink

When a channel is allocated, if the "up/downlink assigned" or "up/downlink assigned for augmented channel allocation" element in the channel allocation indicates that the MS has only been allocated either the uplink or the downlink then (as specified in clause 23.3.4), for the application of the general procedures for transmission and reception of signalling messages, the control channel shall be assumed to occupy any control slots on both the uplink and downlink directions, as indicated by the "timeslot assigned" element in the channel allocation. This applies also to the napping procedure if the MS has been assigned only one direction, so the normal napping procedure applies.

It is possible that the MS may receive concurrent independent channel allocations for the uplink and downlink of the same channel (e.g. both on the MS's individual address, or one on the MS's individual address and the other on one of the MS's group addresses):

- If the napping information is the same for both directions, the MS may assume that the normal napping procedure applies.
- If the napping information is different for the two directions, the MS shall regard the two sets of napping procedures as applying independently. Then:
  - The MS shall attempt to receive and decode downlink slots of the assigned channel if required by either set of napping procedures (within the constraints of the cell reselection procedures, and linearization and transmission requirements).
  - If the BS sends a "replace" or "replace + CSS channel" channel allocation on that channel, it should include a higher layer message, thus enabling the MS to deduce which of the current channel allocations is being replaced (see clause 23.5.4.2.3) - and thereby also enabling the MS to deduce which set of napping information applies on the allocated channel if "napping status" = 10<sub>2</sub>; this applies also for a "quit command". If the MS is unable to deduce which set of napping information applies on the allocated channel then it shall regard both sets of napping information as still applying on the current channel and shall regard napping as not being permitted on the allocated channel.
  - If the BS sends an "add" channel allocation on that channel with "napping status" = 10<sub>2</sub>, the MS shall regard both sets of napping information as applying on the allocated channel.

Alternatively the MS may regard napping as not being applicable.

### 23.4.8.6 BS procedures for supporting MS napping

If the BS supports the use of the napping procedure by MSs, it may include napping information in channel allocations sent to MSs that support the augmented channel allocation (as indicated in the "class of MS" element in the U-LOCATION UPDATE DEMAND PDU).

NOTE 1: MSs that support D8PSK and/or QAM operation need to support the augmented channel allocation in order to be allocated to a D8PSK or QAM channel. It is optional whether an MS that only supports  $\pi/4$ -DQPSK operation supports the augmented channel allocation. The BS designer should note that an MS that does not support the augmented channel allocation will discard augmented channel allocations addressed to itself.

The napping procedure is intended principally for multi-slot channels. However it may be used to enable some battery economy on a single-slot channel if the "napping reception frames" element specifies reception in every two or three TDMA frames.

The methods used by the BS for choosing the napping information are outside the scope of the present document. The choice may be based on a compromise between allowing flexibility of scheduling of the downlink channel and giving opportunities for MS neighbour cell monitoring, irregular channel monitoring, main carrier monitoring, background scanning and/or battery economy. The choice may also depend on whether the BS makes use of the immediate napping permission facility, since the same napping information applies during short gaps in transmission (using the immediate napping permission facility) and during longer gaps (e.g. based on inactivity timer T.226).

NOTE 2: The "immediate napping permission flag" is included in MAC-RESOURCE, MAC-END and MAC-D-BLCK PDUs sent using  $\pi/8$ -D8PSK or QAM modulation, and in MAC-D-BLCK PDUs sent using  $\pi/4$ -DQPSK modulation; however, it is not included in MAC-RESOURCE and MAC-END PDUs sent using  $\pi/4$ -DQPSK modulation. Therefore use of the immediate napping permission facility is restricted on  $\pi/4$ -DQPSK channels and when using  $\pi/4$ -DQPSK modulation on D8PSK channels.

If the BS makes use of the immediate napping permission facility, the methods used by the BS for choosing when to give immediate napping permission are outside the scope of the present document. The methods of use may depend on the type of data being sent by the BS or the MS. For example:

- When the BS is sending background class data to an MS, the BS may choose usually to set the "immediate napping permission flag" to 0 until the end of the data - except when there are intervals when the BS knows that it will be transmitting to other MSs for the next few slots or frames. Thus the MS may be required to receive most of the downlink assigned slots during the data transfer. The MS returns to napping mode at the end of the data, either immediately or after time  $T.226$ , depending on the setting of the "immediate napping permission flag".
- When the MS is sending background class data to the BS, the BS may choose whether to set the "immediate napping permission flag" to 0 or 1 - depending on whether it needs to have flexibility to send acknowledgements and slot grants in any slot of the downlink assigned channel.
- When the BS is sending data involving periodic transmissions of short packets (such as real-time class data or telemetry class data), the BS may choose to set the "immediate napping permission flag" to 1 in most or all downlink MAC PDUs sent to the MS. (For packets that require more than one slot, the flag would be set to 1 only in the last of the slots sent to this MS.)
- When the MS is sending data involving periodic transmissions of short packets, the BS may choose to set the "immediate napping permission flag" to 1 in most or all downlink MAC PDUs sent to the MS e.g. the downlink MAC PDUs containing the slot grants and/or link adaptation feedback messages.

If the BS sends a channel allocation on an assigned channel, allocating another assigned channel, it may set the "napping status" element to  $00_2$  to indicate that use of the napping procedure is not permitted on the allocated channel, or it may set the "napping status" element to  $01_2$  and provide napping information for use on the allocated channel. Alternatively it may set the "napping status" element to  $10_2$  to indicate that current napping information may be used on the allocated channel; for example, this may be used if the BS wishes MSs to retain their current individual napping information after a channel replacement on a group address - particularly if performing the channel replacement using the predefined broadcast group address. (The BS should choose an appropriate method if it wishes to send a channel replacement on a  $\pi/4$ -DQPSK channel using a group address if some MSs in the group support the augmented channel allocation and other MSs do not - for example, sending the augmented channel allocation first.)

## 23.4.9 Link adaptation on D8PSK or QAM channel

### 23.4.9.1 General

On a D8PSK channel, signalling and data messages may generally be sent using either  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK bursts:

- for downlink transmissions in the assigned slots in frames 1 to 17, and in the assigned slots in frame 18 for which  $(MN + TN) \bmod 4 = 2$  or 4, the BS shall choose whether to use a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK burst on a slot-by-slot basis;

NOTE 1: The BS always uses  $\pi/4$ -DQPSK modulation on a D8PSK channel in downlink slots in frame 18 for which  $(MN + TN) \bmod 4 = 1$  or 3.

- for reserved slots and subslots on the uplink, the transmitting MS shall choose whether to use a  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK burst in each slot or subslot.

On a QAM channel, signalling and data messages may generally be sent using any valid combination of modulation and coding rate:

- for downlink transmissions on a DA main carrier in frames 1 to 17, and in the slots in frame 18 for which  $(MN + TN) \bmod 4 = 1, 2$  or 4, the BS shall choose which modulation level and coding rate to use for the SCH-Q/D on a slot-by-slot basis;

NOTE 2: The BS sends the QAM Frequency Correction Burst (FCB) on the DA main carrier in downlink slots in frame 18 for which  $(MN + TN) \bmod 4 = 3$ . The FCB always uses 4-QAM, coding rate =  $1/2$ .

- for downlink transmissions on other QAM carriers, the BS shall choose which modulation level and coding rate to use for the SCH-Q/D on a slot-by-slot basis;
- for reserved uplink slots and subslots on the uplink, the transmitting MS shall choose which modulation level and coding rate to use for the SCH-Q/U in each slot or SCH-Q/HU in each subslot - subject to the maximum uplink modulation level permitted by the BS.

In the link adaptation algorithm, the MAC may evaluate the current state of the link; then, when sending a TM-SDU, the MAC adaptively selects the appropriate modulation level (and coding rate for QAM) to use, based on:

- a) the link conditions; and
- b) the data category parameter in the TMA-UNITDATA request primitive.

NOTE 3: It is not expected that the MS or BS would attempt to follow changes in the link conditions over a period shorter than about half a second.

Alternatively, the MAC may use a predefined choice of modulation levels (and coding rates for QAM) for each of the data categories (or for some of the data categories). Then, when sending a TM-SDU, the MAC selects the appropriate modulation level (and coding rate for QAM) based solely on the data category parameter in the TMA-UNITDATA request primitive.

The data category parameter provides information about the type of data in the TM-SDU and the required reliability level for the transmission. The MS designer should choose an appropriate definition of the data category parameter for the chosen link adaptation algorithm. For example, the data category parameter may indicate whether the data is:

- background class data - reliability level 1; or
- background class data - reliability level 2; or
- background class data - reliability level 3; or
- telemetry class data - reliability level 1; or
- telemetry class data - reliability level 2; or
- telemetry class data - reliability level 3; or
- real-time class data; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 1; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 2; or
- non-classified data (i.e. TM-SDU does not contain packet data) - reliability level 3.

NOTE 4: In this example of possible data categories, it is intended that reliability level 3 refers to better (i.e. higher) reliability than reliability level 2, and reliability level 2 refers to better (i.e. higher) reliability than reliability level 1. See also clause 22.3.1.10.

NOTE 5: In this example of possible data categories, three reliability levels are used for background class data, telemetry class data and non-classified data. In an implementation, fewer than three reliability levels could be used if preferred. For instance, if preferred, two reliability levels could be used for background class data and/or telemetry class data and/or non-classified data.

NOTE 6: The MAC uses both the data class and the reliability level when it selects the appropriate modulation level (and coding rate for QAM). For example, the appropriate modulation level (and/or coding rate for QAM) for "telemetry class data - reliability level 1" may be different from that for "background class data - reliability level 1".

The data category parameter is also used in the buffering process between the LLC and the MAC. It is used in the DATA-IN-BUFFER signal, so that the MS-MAC can estimate the reservation requirement from the amount of data in the LLC buffer per data category; see clause 23.5.2.1. It is also used in the MAC-READY signal; see clause 23.1.2.1.2.

Two layer 2 signalling messages may be used in the link adaptation process:

- the L2-LINK-FEEDBACK-CONTROL message may be used by the BS either:
  - to request link adaptation feedback from the MS on a D8PSK or QAM channel; or
  - to terminate link adaptation feedback from the MS;
- the L2-LINK-FEEDBACK-INFO message may be used by the BS or MS to send link adaptation feedback information on a D8PSK or QAM channel.

The MAC sends and receives layer 2 signalling messages using the data transfer service provided by the LLC at the TLE-SAP; see clause 23.1.4.

## 23.4.9.2 MS choice of bit rate

### 23.4.9.2.1 General on MS choice of bit rate

When on a D8PSK or QAM channel, the MS-MAC shall maintain assessments of the current appropriate bit rate for use for reserved access transmission for each of the data categories i.e.:

- on a D8PSK channel, the appropriate modulation ( $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK) for each data category; or
- on a QAM channel, the appropriate modulation level and coding rate for each data category.

These assessments are used when the MS-MAC has a reserved slot (or subslot) individually granted to it by the BS, as described in clause 23.1.2.1.3. As indicated below, the assessments of the appropriate bit rate for each of the data categories may be adaptive estimates, varying with the current channel conditions, or may be predefined choices.

The MS designer should choose suitable criteria for the MS-MAC to decide on the current appropriate bit rate for each of the data categories. The criteria may be based on various types of information, including the following:

- a) Any L2-LINK-FEEDBACK-INFO messages received from the BS.

The feedback information may indicate the preferred bit rate for a specified data class; alternatively it may provide the BS's estimate of the  $E_s/N_0$  received on the uplink and (optionally) the BS's estimate of the channel model and speed; see clause 21. If the feedback information indicates a preferred bit rate for background class data or telemetry class data, the MS should regard this as applying to the lowest reliability level for that class of data (and the MS should regard lower (or equal) bit rates as applying to the other reliability levels for that class of data).

- b) Link performance information in the TMC-CONFIGURE request primitive.

This parameter may be provided by the LLC, indicating information about the current advanced link performance. For example, the LLC may provide information derived from the acknowledgement bit maps in received AL-ACK, AL-RNR, AL-X-ACK and AL-X-RNR PDUs.

NOTE 1: The method for derivation of this link performance information is outside the scope of the present document. However the following points may be noted:

- If multiple advanced link segments are sent in a single slot, then those segments will all either be successfully received or fail together. This may need to be taken into account if the MS is using a link adaptation algorithm based on estimating slot error rates.
- If the MS has used a mixture of different bit rates to send the segments, it may need to keep a record of the bit rate used to send those segments, for comparison with the information derived from the acknowledgement bit maps - if the MS is using a link adaptation algorithm based on estimating slot error rates at particular bit rate(s).
- If the MS's link adaptation algorithm gives more weighting to the success or failure of segments that were sent recently, the MS may need to keep a record of when segments were sent, for comparison with the information derived from the acknowledgement bit maps.

- c) Measurements of the downlink channel, such as:
- 1) measurements of slot error rates on the downlink channel for different bit rates; and/or
  - 2) other measurements of the downlink channel e.g.  $E_s/N_0$  or RSSI or symbol quality measurements.

Use of this information, together with knowledge of the BS link imbalance and an MS correction factor (see clause 21.5.2a), may enable the MS to make an approximate estimate of the uplink slot error rates.

NOTE 2: When making measurements of the downlink channel, the MS may use information from any downlink slots on the channel, not only those slots containing information addressed to itself. In case c1):

- on a D8PSK channel, the MS determines whether a downlink slot contains a  $\pi/4$ -DQPSK normal downlink burst or a  $\pi/8$ -D8PSK normal downlink burst by inspecting the training sequence;
- on a QAM channel, the MS first attempts to decode the QAM-SLOTINFO PDU in the SICH-Q/D in order to determine the bit rate used in the remainder of the slot; it may record the decode failure rate for any slots on the downlink channel for which it can decode the QAM-SLOTINFO PDU. (It may not be appropriate for the MS to use the decode failure rate for slots for which the QAM-SLOTINFO PDU indicates that the burst is an FCB.)

- d) Choice of predefined bit rates for each of the data categories.

This choice of predefined bit rates may be made by the MS designer.

Predefined bit rates may be used in different ways; for example:

- 1) predefined bit rates may be used temporarily as a default in the absence of preferred information;
- 2) alternatively, the MS designer may choose to use suitable predefined bit rates for each of the data categories in general (or for some of the data categories), in order to provide a simple link adaptation algorithm; see also clause 23.4.9.2.2.

The information used may depend on the data category; for example, use of method b) is not appropriate when the MS is sending real-time class data. Also, use of method b) may not be appropriate for infrequent telemetry class data.

The information used may also depend on whether the MS is starting to send data (or a significant time has elapsed since the MS last transmitted data) or whether the MS has been transmitting data for some time. For example:

- use of method b) is not appropriate when the MS is starting to send advanced link data or if a significant time has elapsed since the MS last transmitted advanced link data;
- when the MS is starting to send advanced link data or if a significant time has elapsed since the MS last transmitted advanced link data, the MS could use method c) or use a predefined choice of bit rate;
- when the MS is starting to send real-time data, the MS could use method c) or use a predefined bit rate.

NOTE 3: For a DA MS, the information used may also depend on whether the MS is on its common control channel or on an assigned channel. For example, when a DA MS is idle on its common control channel, the MS might use a simpler method than when it is on an assigned channel.

NOTE 4: If an MS is not frequency full duplex and is operating on a multi-slot channel (e.g. a multi-slot assigned channel), it may not be able to receive the downlink channel during the elapse time corresponding to one granted capacity allocation, depending on the MS's fast switching capability and the timeslots belonging to the channel. (For multiple slot granting, the MS can receive the downlink channel between each instance of capacity allocation for appropriate values of the granting delay.) If the MS cannot receive the downlink channel during the elapse time corresponding to a capacity allocation, it cannot receive L2-FEEDBACK-INFO messages or acknowledgement bit maps from the BS, or make measurements of the downlink channel, during the elapse time corresponding to that capacity allocation. In this case, the BS may choose to limit the size of each instance of the capacity allocation. This may apply particularly when the BS perceives that the quality of the link is currently variable such that the MS may wish to adapt its bit rate more frequently than the maximum length of capacity allocation.

If the MS maintains an adaptive estimate of the appropriate bit rate for each of the data categories (varying with the current channel conditions) then:

- In the absence of feedback information from the BS indicating a preferred bit rate, the MS may use the chosen information in order to choose a bit rate such that the actual uplink slot error rate for each data category is intended to lie within a target range. The target range would generally be different for the different data categories. The choice involves a trade-off between throughput and reliability of a single transmission: if the uplink slot error rate exceeds the maximum acceptable then a lower bit rate may be appropriate in order to achieve more reliability; whereas, if the uplink slot error rate is less than the minimum in the target range then a higher bit rate may be appropriate in order to achieve higher throughput.
- When choosing an algorithm for making an adaptive estimate of the appropriate bit rate:
  - it is expected that the MS designer may choose an algorithm which allows relatively high slot error rates to be used for "background class data - reliability level 1", thereby enabling choice of higher bit rates and therefore higher throughput, and relying on the advanced link retransmission protocol in the case of failed segments; then more moderate slot error rates may apply for "background class data - reliability level 2"; and lower slot error rates should apply for "background class data - reliability level 3" (which may be used when the maximum number of segment retransmissions will soon be exceeded);
  - it is expected that the MS designer would choose an algorithm with relatively low slot error rates for "real-time class data";
  - it is expected that the MS designer would choose an algorithm with relatively low slot error rates for "non-classified data - reliability level 3";
  - it is expected that the MS designer may choose an algorithm which allows intermediate slot error rates to be used for "telemetry class data - reliability level 1" (i.e. lower than for "background class data - reliability level 1"); then reduced slot error rates may apply for "telemetry class data - reliability level 2"; and lower slot error rates should apply for "telemetry class data - reliability level 3" (which may be used when the maximum number of segment retransmissions will soon be exceeded).

NOTE 5: Use of a predefined choice of bit rates may be more appropriate for infrequent telemetry class data.

NOTE 6: If fewer than three reliability levels are used then appropriate target ranges for slot error rates may still apply. For example, if using two reliability levels for background class data, the MS designer may choose an algorithm which allows relatively high slot error rates to be used for "background class data - reliability level 1"; then lower slot error rates should apply for "background class data - reliability level 2" (which is used when the maximum number of segment retransmissions will soon be exceeded).

The following additional points may be noted relating to transmission on a QAM channel:

- when the MS transmits in a slot or subslot, it shall not exceed the maximum uplink QAM modulation level permitted by the BS;
- if the MS is capable of using 64-QAM, and the BS permits use of 64-QAM on the uplink, the MS should use 64-QAM in preference to using 16-QAM with coding rate  $r = 1$ .

## 23.4.9.2.2 Suggested predefined bit rates for background class and telemetry class data

### 23.4.9.2.2.1 General

Clause 23.4.9.2.1 gives general information on MS choice of bit rate. The MS designer should choose suitable criteria for the MS to decide on the current appropriate bit rate for each of the data categories. The assessments of the appropriate bit rate for each of the data categories may be adaptive estimates, varying with the current channel conditions, or may be predefined choices.

Clauses 23.4.9.2.2.2 and 23.4.9.2.2.3 suggest possible choices of predefined bit rates for background class data and telemetry class data. The MS should use appropriate bit rates for each of the data categories for background class data and telemetry class data to provide performance equal to or better than use of these suggested predefined bit rates.

NOTE: The suggested predefined bit rates in clauses 23.4.9.2.2.2 and 23.4.9.2.2.3 provide a simple link adaptation algorithm for background class data and telemetry class data. It is expected that a simple link adaptation algorithm using a predefined choice of bit rates may be the most appropriate for telemetry class data because link performance information may be out-of-date. However, it is expected that, at least for background class data, MS designers may prefer to use adaptive estimates of the appropriate bit rates in such a way as to provide better performance.

#### 23.4.9.2.2.2 Suggested predefined bit rates on D8PSK channel

For background class data and telemetry class data, if the maximum number of segment retransmissions (LLC parameter N.274) is at least three, the MS should use appropriate bit rates for each of the data categories to provide performance equal to or better than use of the following predefined choices:

- one transmission of each segment at reliability level 1, using  $\pi/8$ -D8PSK modulation;
- if retransmission of a segment is needed:
  - one transmission of that segment at reliability level 2, using  $\pi/8$ -D8PSK modulation;
- then, if retransmission of the segment is still needed:
  - further transmission(s) of that segment at reliability level 3, using  $\pi/4$ -DQPSK modulation.

As indicated in clause 22.3.1.10, the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may depend on the maximum number of segment retransmissions N.274 for that advanced link.

Also, in an implementation, there may be some variations according to the current channel conditions (without necessarily using full adaptive estimates); for example:

- a) the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may vary according to the current channel conditions, based on information provided by the MAC to the LLC;
- b) when appropriate, the MS may revert to using fewer than three reliability levels;
- c) when the channel conditions are perceived as poor, the MS could decide adaptively not to attempt any segment transmissions using  $\pi/8$ -D8PSK modulation until the channel conditions are perceived to have improved.

NOTE: On a D8PSK channel, fragmentation is generally needed when a segment first sent using  $\pi/8$ -D8PSK modulation is retransmitted using  $\pi/4$ -DQPSK modulation (because the segment is cut to match the size of a  $\pi/8$ -D8PSK MAC block). This impairs the performance of the  $\pi/4$ -DQPSK retransmission compared with the performance if the segment had been first sent using  $\pi/4$ -DQPSK modulation (in which case the segment would have been cut to match the size of a  $\pi/4$ -DQPSK MAC block). Therefore, as indicated in point c), the MS may choose not to attempt any segment transmissions using  $\pi/8$ -D8PSK modulation when the MS perceives that a  $\pi/8$ -D8PSK transmission would be unlikely to be successfully received.

#### 23.4.9.2.2.3 Suggested predefined bit rates on QAM channel

For background class data and telemetry class data, if the maximum number of segment retransmissions (LLC parameter N.274) is at least three, the MS should use appropriate bit rates for each of the data categories to provide performance equal to or better than use of the following predefined choices:

- one transmission of each segment at reliability level 1:
  - using 64-QAM rate = 2/3 if the BS permits use of 64-QAM on the uplink; else
  - using 16-QAM rate = 1/2;
- if retransmission of a segment is needed:
  - one transmission of that segment at reliability level 2, using 16-QAM rate = 1/2;
- then, if retransmission of the segment is still needed:
  - further transmission(s) of that segment at reliability level 3, using 4-QAM rate = 1/2.

As indicated in clause 22.3.1.10, the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may depend on the maximum number of segment retransmissions  $N_{274}$  for that advanced link.

Also, in an implementation, there may be some variations according to the current channel conditions (without necessarily using full adaptive estimates); for example:

- a) the maximum number of segment transmissions using reliability level 1 (and/or reliability level 2) may vary according to the current channel conditions, based on information provided by the MAC to the LLC;
- b) when appropriate, the MS may revert to using fewer than three reliability levels;
- c) when the channel conditions are perceived as poor, the MS could decide adaptively not to attempt any segment transmissions using 64-QAM until the channel conditions are perceived to have improved.

NOTE: Fragmentation is not generally needed when a segment first sent using 64-QAM is retransmitted using 16-QAM or 4-QAM, or when a segment first sent using 16-QAM is retransmitted using 4-QAM.

### 23.4.9.3 BS choice of bit rate

The BS designer should choose suitable criteria for the MAC in the BS to decide on the appropriate bit rate in each downlink slot. The criteria for the BS to decide on an appropriate bit rate to use when sending data of a particular category to an MS may be based on various types of information, including the following:

- a) any L2-LINK-FEEDBACK-INFO messages received from that MS; and/or
- b) link performance information relating to current advanced link performance (such as information derived from the acknowledgement bit maps in received AL-ACK, AL-RNR, AL-X-ACK and AL-X-RNR PDUs); and/or
- c) measurements of the uplink slots and subslots used by that MS; and/or
- d) choice of predefined bit rates for each of the data categories (or for some of the data categories), for example:
  - for temporary use as a default in the absence of preferred information; or
  - for use in general, in order to provide a simple link adaptation algorithm.

The information used may depend on whether the BS is starting to send data to the MS (or a significant time has elapsed since the BS last transmitted data to the MS) or whether the BS has been transmitting data to the MS for some time.

The BS may include signalling or data messages for more than one MS within one downlink slot. The BS should take account of the appropriate bit rate for transmission to each MS when deciding which messages to associate within a slot and when choosing the bit rate to use in the slot.

NOTE: It is recommended that PDUs containing slot grants are sent using a high reliability.

The following additional points may be noted relating to transmission on a QAM channel:

- the BS should not exceed the maximum QAM modulation level supported by that MS for reception;
- if the BS and MS are both capable of using 64-QAM, the BS should use 64-QAM in preference to using 16-QAM with coding rate  $r = 1$ .

### 23.4.9.4 Link adaptation feedback control by BS

The BS may send the L2-LINK-FEEDBACK-CONTROL message either:

- to request link adaptation feedback from the MS on a D8PSK or QAM channel; or
- to terminate link adaptation feedback from the MS.

The request for link adaptation feedback may solicit a single feedback message from the MS, or it may also invite feedback from the MS, following a change in channel conditions, for a specified feedback duration. When the BS sends a request for link adaptation feedback, it may include a slot grant (e.g. granting a subslot) for the solicited feedback message from the MS.

The request for link adaptation feedback indicates a preferred channel metric type (and the appropriate data class in the case of a request for bit rate feedback). However the BS should note that the MS may send feedback with a different channel metric type if it does not support the preferred channel metric type.

It is recommended that the BS requests link adaptation feedback during transmission of real-time class data to an individual MS if the BS wishes to use link adaptation for that data.

The BS may request link adaptation feedback during transmission of telemetry class data and/or background class data.

The termination of link adaptation feedback message indicates the channel metric type (and the data class in the case of bit rate feedback) to which the termination applies.

### 23.4.9.5 Link adaptation feedback by MS

#### 23.4.9.5.1 Sending link adaptation feedback

On receipt of an L2-LINK-FEEDBACK-CONTROL message (delivered by the LLC in a TLE-UNITDATA indication primitive), the MS-MAC shall inspect the "link feedback control type" element.

If the "link feedback control type" element is set to 000<sub>2</sub>, indicating a request for feedback, the MS-MAC shall send an L2-LINK-FEEDBACK-INFO message. The L2-LINK-FEEDBACK-CONTROL message indicates the preferred channel metric type for the feedback (and the appropriate data class in the case of a request for bit rate feedback). If the MS supports the preferred channel metric type, it shall send the information corresponding to that channel metric type (and that data class in the case of bit rate feedback) in the L2-LINK-FEEDBACK-INFO message; otherwise it shall send information corresponding to a channel metric type that it supports.

If the L2-LINK-FEEDBACK-CONTROL feedback request message contains "feedback duration T.230" element set to 000000<sub>2</sub>, the MS-MAC shall not send any further L2-LINK-FEEDBACK-INFO messages relating to this feedback request.

If the L2-LINK-FEEDBACK-CONTROL feedback request message contains "feedback duration T.230" element not equal to 000000<sub>2</sub>, the MS-MAC may send further L2-LINK-FEEDBACK-INFO messages relating to this feedback request (designated "unsolicited" feedback messages) - when there has been a significant change in the perceived channel conditions and within the T.231 constraints defined below - until either:

- a) the MS-MAC receives a further L2-LINK-FEEDBACK-CONTROL feedback request message containing the same channel metric type (and data class in the case of a request for bit rate feedback); or
- b) the MS-MAC receives an L2-LINK-FEEDBACK-CONTROL feedback termination message containing the same channel metric type (and data class in the case of bit rate feedback) as in the L2-LINK-FEEDBACK-CONTROL feedback request message; or
- c) a time T.230 has elapsed since receipt of the L2-LINK-FEEDBACK-CONTROL feedback request message; or
- d) the MS leaves the current channel (or changes from assigned mode to common mode), unless the MS is leaving the channel as a result of obeying an augmented channel allocation within the current cell and with:
  - i) "allocation type" element set to 00<sub>2</sub> (Replace) or 11<sub>2</sub> (Replace + CSS channel); and
  - ii) "modulation mode of allocated channel" element indicating that the allocated channel is a D8PSK or QAM channel; and
  - iii) "timeslot assigned" element not set to 0000<sub>2</sub>.

NOTE 1: For the purposes of criterion d), the MS should regard changing from assigned mode to common mode on the same physical channel(s) as leaving the current channel.

NOTE 2: If the MS leaves the current channel as a result of obeying an augmented channel allocation within the current cell and satisfying criteria i), ii) and iii), it may send further L2-LINK-FEEDBACK-INFO messages on the allocated channel (when there has been a significant change in the perceived channel conditions and within the T.231 constraints defined below) until one of criteria a), b), c) or d) applies.

In case a), the MS shall process the L2-LINK-FEEDBACK-CONTROL feedback request message as described above (responding with an L2-LINK-FEEDBACK-INFO message and then, if the "feedback duration T.230" element is not 000000<sub>2</sub>, optionally sending further L2-LINK-FEEDBACK-INFO messages - subject to the constraints below).

During the time when unsolicited feedback is permitted:

- 1) the MS-MAC shall not send an L2-LINK-FEEDBACK-INFO message relating to this feedback request unless the minimum time interval T.231 has elapsed since the MS-MAC last sent an L2-LINK-FEEDBACK-INFO message relating to this feedback request;
- 2) the MS-MAC should send an L2-LINK-FEEDBACK-INFO message if:
  - there has been a significant change in the perceived channel conditions since the last feedback relating to this feedback request, such as a change in the preferred bit rate for this data class or a significant change in the  $E_s/N_0$  feedback information; and
  - the minimum time interval T.231 has elapsed since the MS-MAC last sent an L2-LINK-FEEDBACK-INFO message relating to this feedback request;
- 3) the MS-MAC may send an L2-LINK-FEEDBACK-INFO message if:
  - there has been a significant change in the perceived channel conditions since the last feedback relating to this feedback request sent either as the immediate response to the L2-LINK-FEEDBACK-CONTROL feedback request message or by successful random access; and
  - the minimum time interval T.231 has elapsed since the MS-MAC last sent an L2-LINK-FEEDBACK-INFO message relating to this feedback request;

however, the MS-MAC shall not send the same or similar information more than a total of N.231 times.

NOTE 3: If a feedback message was sent as the immediate response to a feedback request message, it is the BS's responsibility to send the feedback request message again if the response was not received.

NOTE 4: If a feedback message was successfully sent by random access, the MS-MAC can deduce that the message was received by the BS.

NOTE 5: If a feedback message indicating a significant change in the perceived channel conditions was sent by reserved access, and not as the immediate response to a feedback request message, or if the transfer failed, the MS-MAC may send another feedback message after expiry of timer T.231 (and possibly again after the next expiry of timer T.231 if the feedback message was again sent by reserved access) - within the limit defined by N.231; see point 3) above. This may apply particularly if the number of repetitions of the layer 2 signalling message was 0. However, the MS-MAC should not continually send the same information after each expiry of timer T.231 unless there is another significant change in the perceived channel conditions. Also, if the number of repetitions of the layer 2 signalling message was not 0, the MS-MAC should reduce the value of N.231 accordingly

The MS may receive L2-LINK-FEEDBACK-CONTROL feedback request messages from the BS inviting unsolicited feedback messages relating to different channel metric types or different data class linkage. Then the above procedures for unsolicited feedback messages generally apply independently to each of the feedback request messages. However, if the MS is unable to support the preferred channel metric type and so sends information corresponding to the same channel metric type (and data class) in response to more than one feedback request then, when there is a significant change in the perceived channel conditions, the MS should only send the L2-LINK-FEEDBACK-INFO message according to the procedures for one of those feedback requests (e.g. when first permitted by one of the T.231 timers).

When the MS-MAC sends an L2-LINK-FEEDBACK-INFO message, it shall issue the message to the LLC in a TLE-UNITDATA request primitive. The MS-MAC should set PDU priority level = 6 in the request primitive. When the message is sent as the immediate response to an L2-LINK-FEEDBACK-CONTROL feedback request, the number of repetitions of the layer 2 signalling message shall be set to 0. For an unsolicited feedback message, it is recommended that the number of repetitions of the layer 2 signalling message is normally set to 0.

If the MS-MAC sends an L2-LINK-FEEDBACK-INFO message, and there is a significant change in the perceived channel conditions before the MS-MAC receives a TLE-REPORT indication primitive reporting completion of the transfer (either successful or failed transfer), the MS-MAC may cancel the ongoing transfer using the TLE-CANCEL request primitive and then send a revised L2-LINK-FEEDBACK-INFO message.

### 23.4.9.5.2 MS feedback information

When the MS-MAC sends an L2-LINK-FEEDBACK-INFO message, as defined in clause 23.4.9.5.1, it may indicate:

- the preferred bit rate for reception of data for a specified data class; or
- the MS's estimate of the  $E_s/N_0$  received on the downlink and (optionally) the MS's estimate of the channel model and speed.

If the feedback information indicates a preferred bit rate for background class data or telemetry class data, this refers to the preferred bit rate for the lowest reliability level for that class of data.

The MS designer should choose suitable methods for the MS to derive the preferred bit rate or to estimate the  $E_s/N_0$  received on the downlink and the channel model and speed.

In order to derive or estimate this information, the MS needs to make measurements of the downlink channel, such as:

- 1) measurements of slot error rates on the downlink channel for different bit rates; and/or
- 2) other measurements of the downlink channel e.g.  $E_s/N_0$  or RSSI or symbol quality measurements.

NOTE: When making measurements of the downlink channel, the MS may use information from any downlink slots on the channel, not only those slots containing information addressed to itself.

If the MS indicates the preferred bit rate for reception of data for a specified data class, it may use the measurements in order to choose that preferred bit rate such that the actual downlink slot error rate for the data is intended to lie within a target range. The target range may be different for the different data classes, since it involves a trade-off between throughput and reliability of a single transmission; for example, when choosing the preferred bit rate:

- for background class data, the MS may select a preferred bit rate corresponding to a relatively high slot error rate, thereby enabling a higher bit rate and therefore higher throughput (relying on the advanced link retransmission protocol in the case of failed segments);
- for real-time class data, the MS may select a preferred bit rate corresponding to a relatively low slot error rate;
- for telemetry class data, an intermediate choice may be appropriate.

On a QAM channel, if the MS indicates the preferred bit rate, the MS shall not indicate a QAM modulation level exceeding the maximum uplink QAM modulation level permitted by the BS. If the BS does not support transmission at the indicated QAM modulation level, it may use a lower modulation level that it supports (with an appropriate coding rate). Similarly, if the indicated coding rate is coding rate  $r = 1$ , and the BS does not support transmission using coding rate  $r = 1$ , the BS should use a coding rate that it supports.

### 23.4.9.6 Link adaptation feedback by BS

The BS may send the L2-LINK-FEEDBACK-INFO message to an MS at any time in order to provide link adaptation information. When the BS sends a link adaptation feedback message, it may include a slot grant for the MS's data.

It is recommended that the BS sends link adaptation feedback when the MS is transmitting real-time class data if it wishes to enable the MS to use link adaptation for that data.

The BS may send link adaptation feedback when the MS is transmitting background class data and/or telemetry class data. (This may not be useful for infrequent uplink telemetry class data.)

The feedback information may indicate the preferred bit rate for a specified data class; alternatively it may provide the BS's estimate of the  $E_s/N_0$  received on the uplink and (optionally) the BS's estimate of the channel model and speed.

The BS designer should choose suitable methods for the BS to derive the preferred bit rate or to estimate the  $E_s/N_0$  received on the uplink and the channel model and speed.

On a QAM channel, if the BS indicates the preferred bit rate, the BS shall not indicate a QAM modulation level exceeding the maximum QAM modulation level supported by that MS for reception. If the MS does not support transmission at the indicated QAM modulation level, it should use a lower modulation level that it supports (with an appropriate coding rate). Similarly, if the indicated coding rate is coding rate  $r = 1$ , and the MS does not support transmission using coding rate  $r = 1$ , the MS should use a coding rate that it supports.

EXAMPLE: If the MS supports reception but not transmission using 64-QAM then:

- if the BS indicates 64-QAM rate = 1/2 as the preferred bit rate, the MS should use 16-QAM rate = 1/2;
- if the BS indicates 64-QAM rate = 2/3 as the preferred bit rate, the MS may choose to use either 16-QAM rate = 1/2 or 16-QAM rate = 1;
- if the BS indicates 64-QAM rate = 1 as the preferred bit rate, the MS should use 16-QAM rate = 1 if supported for transmission or else should use 16-QAM rate = 1/2.

## 23.4.10 MAC aspects of assigned channel replacement on serving cell

### 23.4.10.1 MS-MAC advice to MLE on assigned channel replacement

The MLE in the MS may request the SwMI to replace an assigned channel on the serving cell; see clause 18. The criteria used by the MLE to decide whether to request assigned channel replacement may include use of information provided by the MS-MAC about whether the MS-MAC considers that:

- a) channel replacement is advisable (for example, if an RF bandwidth reduction or a change of sector or eccentric channel may be advisable because reliability performance on the current channel may not be acceptable); or
- b) channel replacement may be beneficial (for example, because performance on the current channel is good and a bandwidth increase might have a beneficial effect on data throughput); or
- c) performance on the current channel is acceptable.

When the MS-MAC provides this information to the MLE, it shall use a TMC-REPORT indication primitive.

NOTE 1: The MLE also uses path loss parameters (C1, C2, C4 and C5) provided by the MS-MAC in its criteria for requesting assigned channel replacement. See clause 23.7 for the definition of the path loss parameters.

The MS designer should choose suitable criteria for the MS-MAC to issue the TMC-REPORT indication primitive to provide information relating to assigned channel replacement. The criteria may be similar in principle to those used in link adaptation if the MS maintains an adaptive estimate of the appropriate bit rate for each of the data categories, varying with the current channel conditions (see clause 23.4.9.2), or when the MS sends a preferred bit rate for reception of data (see clause 23.4.9.5.2). However, in the case of assigned channel replacement, the criteria may be based on the most demanding data class for currently active PDP context(s) using the current channel; the information about the most demanding data class is provided to the MS-MAC using the TMC-CONFIGURE request primitive ("data class activity information" parameter).

NOTE 2: The real-time data class is more demanding than the telemetry data class, and the telemetry data class is more demanding than the background data class. The term "more demanding" here refers to reliability of transmission at the MAC layer.

For link adaptation, if the MS maintains an adaptive estimate of the appropriate bit rate for each of the data categories (varying with the current channel conditions), the MS may attempt to choose a bit rate such that the actual slot error rate for each data category or data class is intended to lie within a target range, where the target range may be different for the different data categories or data classes since it involves a trade-off between throughput and reliability of a single transmission; see clauses 23.4.9.2 and 23.4.9.5.2. Then, for example, for assigned channel replacement, the MS-MAC criteria for issuing the TMC-REPORT indication primitive might include the following or similar criteria:

- i) the MS-MAC might choose to indicate that channel replacement is advisable if the measured or estimated downlink slot error rate for the lowest modulation level, or the estimated uplink slot error rate (if available) for the lowest modulation level, exceeds either:
  - the maximum acceptable slot error rate for the most demanding data class (see note 3); or
  - the maximum acceptable slot error rate for non-classified data i.e. messages not containing packet data (see note 4);
- ii) the MS-MAC might choose to indicate that channel replacement may be beneficial if:
  - the MS is capable of using a higher bandwidth channel; and
  - the measured or estimated downlink slot error rate for the highest bit rate on the current channel and the estimated uplink slot error rate (if available) for the highest bit rate on the current channel are both less than the minimum slot error rate in the target range for the most demanding data class (see note 5 and note 6).

NOTE 3: In case i), if the most demanding data class is the background data class or the telemetry data class, it may be preferable for the MS-MAC to advise channel replacement based on the maximum acceptable slot error rate for reliability level 3 rather than reliability level 1 or reliability level 2 (if using three reliability levels). If the most demanding data class is the real-time data class, it may be appropriate for the MS-MAC to advise channel replacement if the lost N-PDU probability for real-time class data is greater than (or equal to) 2,5 %; see also clause 28.

NOTE 4: In case i), it may be preferable for the MS-MAC to advise channel replacement based on the maximum acceptable slot error rate for non-classified data with reliability level 3 rather than reliability level 1 or reliability level 2 (if using three reliability levels).

NOTE 5: In case ii), when the MS-MAC is checking whether downlink and uplink slot error rates for the highest bit rate on the current channel are less than the minimum slot error rate in the target range for the most demanding data class, it may be preferable for the MS-MAC to exclude coding rate  $r = 1$  (even if it supports transmission at coding rate  $r = 1$ ). Then, for the purposes of the procedure in case ii), the MS-MAC would treat the highest bit rate on the current channel as being either 16-QAM rate = 1/2 or 64-QAM rate = 2/3 as appropriate.

NOTE 6: The MS-MAC's criteria for indicating that channel replacement may be beneficial may be affected by whether the MS is currently limiting its power as a result of the MS open loop power control procedure (see clause 23.4.4.2.2).

### 23.4.10.2 Assigned channel replacement by BS

When an MS is on an assigned channel, the BS may choose to move the MS to a different channel at any time (for example, from one QAM channel to another QAM channel with a different bandwidth) - based on its observations of the performance of the current channel and the MS's capabilities. It may also move the MS to a different channel as a result of any assigned channel replacement requests received from the MS at MLE level.

NOTE: If the BS accepts an assigned channel replacement request from the MS, the channel allocation need not be to an irregular channel or channel class requested by the MS. For example, in some cases, it may be appropriate for the BS to allocate a channel whose existence has not been broadcast to MSs because the channel fully covers the area covered by the main carrier.

The BS shall not send a channel allocation to an MS that is using an eccentric channel allocating the MS to another eccentric channel on the same cell where the separation between the transmitter sites of the two eccentric channels is more than 4 km; see clause 7.

## 23.5 PDU transfer for signalling messages (TMA-SAP)

### 23.5.1 Random access protocol

#### 23.5.1.1 Introduction

The MS-MAC layer uses the random access protocol to initiate information transfer to the BS. The random access protocol is generally used for unsolicited MS messages, whereas messages solicited by the BS are sent using reserved access.

The random access protocol is based on slotted ALOHA procedures, with a superimposed access framing structure. By a suitable choice of access parameters, it is possible for the BS to:

- control the collision of access requests from different MSs;
- minimize access delay and traffic loss for a particular traffic loading;
- maintain peak throughput for a particular traffic loading;
- avoid protocol instability;
- dynamically restrict random access to different access priorities, and to selected groups and subscriber classes;
- provide simultaneously, independent access grades of service for different groups and subscriber classes.

The random access procedures defined in clauses 23.5.1.2, 23.5.1.3 and 23.5.1.4 are suitable for use on all types of control channel.

#### 23.5.1.2 Overview

##### 23.5.1.2.1 General

This clause provides a general overview of the random access protocol. The precise protocol definition is contained in clauses 23.5.1.3 and 23.5.1.4.

The BS may offer random access opportunities to different sets of MSs in turn by using "Access Codes". There is a maximum of four possible access codes (denoted A, B, C and D), and the BS marks each access opportunity with the appropriate access code. Alternatively, the BS may use a single access code.

The binding of MSs to access codes is dynamic. The binding defines the minimum valid PDU priority for an access code. It may also restrict use of the access code to a set of subscriber classes, or to a group of MSs. An MS may use a subslot designated for a particular access code only if the PDU priority (as supplied by layer 3), and the subscriber class parameter or MS identity, conform to the current binding.

For a particular access code, requests from MSs are invited within "access frames" consisting of a number of access opportunities (uplink subslots).

The random access procedures are based on two types of PDU broadcast by the BS. The PDUs are:

i) The ACCESS-DEFINE PDU

This PDU is transmitted at intervals, how often being an operator option. It contains fairly slowly changing information about the random access parameters for an access code:

- the PDU priority and MS binding to the access code;
- a parameter (IMM) defining when immediate access is permitted for the first transmission;
- the waiting time (WT) before deciding to re-try;
- the permitted number of random access retries;

- a frame-length multiplying factor;
- the uplink random access channel configuration.

ii) The ACCESS-ASSIGN PDU

This PDU:

- is transmitted in every downlink slot of a  $\pi/4$ -DQPSK or D8PSK channel, on the AACH;
- may be transmitted in downlink slots of a QAM channel (except slots containing BLCH-Q), on the AACH-Q.

NOTE 1: The BS always includes the ACCESS-ASSIGN PDU within the AACH. In the present document, the BS should include the ACCESS-ASSIGN PDU within the AACH-Q. However, in future editions of the present document, the BS may choose not to include the ACCESS-ASSIGN PDU in the AACH-Q in some downlink slots on a QAM channel (see clause 21.4.7.1). Therefore the MS should expect that the ACCESS-ASSIGN PDU may not be present in the AACH-Q.

The ACCESS-ASSIGN PDU conveys information about the usage of the downlink slot in which it appears, and also access rights for the corresponding (same-numbered) uplink timeslot of that TDMA frame.

When the uplink is in use for control signalling, the ACCESS-ASSIGN PDU may contain two "Access Fields" which convey independent access rights for each of the two uplink subslots in the uplink slot.

The access field defines the allowed access code for the uplink subslot. It also may include a frame-length parameter. Otherwise, it may indicate that the uplink subslot is reserved for use by one MS and is therefore not available for random access; or it may assign the subslot for common linearization.

In other cases (for example, in frames 1 to 17 on an assigned SCCH), the ACCESS-ASSIGN PDU contains only one access field, which conveys access rights for both uplink subslots in the uplink slot.

When the uplink is in use for traffic, the ACCESS-ASSIGN PDU contains no access field, in which case the uplink slot is not available for random access or common linearization.

NOTE 2: If the AACH or AACH-Q is not decodeable or, on a QAM channel, if the ACCESS-ASSIGN PDU is not present within the AACH-Q, the MS regards the corresponding uplink slot as not available for random access or common linearization.

Also, the SYSINFO PDU, SYSINFO-Q PDU and SYSINFO-DA PDU may include some default parameters to be assumed, for access code A, by MSs that have acquired the main carrier (until receipt of ACCESS-DEFINE PDUs). For BSs that do not need multiple access codes, the facilities provided by the SYSINFO, SYSINFO-Q and SYSINFO-DA PDU may be adequate, so that the ACCESS-DEFINE PDU is not used.

The BS may optimize the system performance by varying the access code bindings, the frame-length and the other access parameters. The choice of parameters will depend on the type of system and the traffic mix.

### 23.5.1.2.2 Overview of random access channel on a 25 kHz channel

The basic format of the random access channel is illustrated in figures 23.9 to 23.12 inclusive.

NOTE: In these representations, the detailed TDMA frame structure (e.g. with a control timeslot and three traffic timeslots per TDMA frame) is not shown. The uplink control subslots (half timeslots) for this control channel are shown as if they were contiguous.

Figure 23.9 illustrates an example of designation of uplink subslots on a common control channel, showing multiple access codes and reserved subslots. The designation is performed using the ACCESS-ASSIGN PDU, with two access fields in the ACCESS-ASSIGN PDU defining the use of the two corresponding uplink subslots.

**Figure 23.12: Example of random access procedure (BS using discrete access frames)**

In either case, the BS may assess activity on the uplink channel in the subslots assigned to the access code, and may vary the frame-length to prevent excessive collision and to minimize access delays. Under normal conditions, the frame-length can be short. Then, when collision is detected, the BS may increase the frame-length dynamically according to its estimate of the backlogged traffic. This allows rapid smoothing of traffic transients.

### 23.5.1.2.3 Overview of random access channel on a 50 kHz, 100 kHz or 150 kHz QAM channel

There is an additional step in the procedure for random access on 50 kHz, 100 kHz and 150 kHz QAM channels as follows.

Access requests are sent within a 25 kHz bandwidth for all QAM channels. Each subslot (i.e. half timeslot) that is available for random access is divided into 25 kHz frequency blocks - called random access uplink RF channel subslots - so that each subslot provides:

- 2 random access uplink RF channel subslots on a 50 kHz channel;
- 4 random access uplink RF channel subslots on a 100 kHz channel; or
- 6 random access uplink RF channel subslots on a 150 kHz channel.

The MS uses the normal procedures for choosing a subslot randomly from an access frame and then counting the subslots to its chosen subslot. Thus, for the purposes of counting subslots in an access frame, the parallel random access uplink RF channel subslots are regarded as a single subslot. However, when the MS reaches its chosen subslot, there is then an additional procedure whereby the MS makes a random choice of one of the 2, 4 or 6 random access uplink RF channel subslots corresponding to its chosen subslot. The MS then transmits its access request in the selected random access uplink RF channel subslot.

## 23.5.1.3 Access control facilities for BS

### 23.5.1.3.0 General

See also the MS random access protocol (clause 23.5.1.4).

#### 23.5.1.3.1 Transmission of ACCESS-DEFINE and ACCESS-ASSIGN PDU

The BS may transmit ACCESS-DEFINE PDUs at intervals decided by the operator. The BS shall transmit the ACCESS-ASSIGN PDU in every downlink timeslot on a  $\pi/4$ -DQPSK or D8PSK channel, and should transmit the ACCESS-ASSIGN PDU in every downlink timeslot on a QAM channel (except slots containing BLCH-Q). The formats of the ACCESS-DEFINE and ACCESS-ASSIGN PDUs are defined in clause 21. Between them, these PDUs shall indicate:

- the configuration of the random access channel for this control channel;
- the valid priorities and the MSs eligible for each uplink subslot;
- the frame-lengths to be used; and

- other ALOHA re-try parameters.

Also:

- the BS may include in the SYSINFO PDU some default random access parameters to be assumed by MSs on phase modulation channels, for access code A, until receipt of ACCESS-DEFINE PDUs;
- the BS may include in the SYSINFO-Q PDU some default random access parameters to be assumed by CA MSs on QAM channels, for access code A, until receipt of ACCESS-DEFINE PDUs;
- the BS may include in the SYSINFO-DA PDU some default random access parameters to be assumed by DA MSs on QAM channels, for access code A, until receipt of ACCESS-DEFINE PDUs.

The following points may be noted:

- MSs that have missed ACCESS-DEFINE PDU broadcasts will be unaware of some of the current access restrictions and will be applying the limitations of the last received ACCESS-DEFINE PDU (or SYSINFO, SYSINFO-Q or SYSINFO-DA information).
- MSs count subslots in access frames using only the ACCESS-ASSIGN PDUs that they receive. Therefore, in case of un-decodeable ACCESS-ASSIGN PDUs, not all MSs will count the subslots in exactly the same way.
- Use of the ACCESS-DEFINE PDU is not required if the facilities provided within the SYSINFO, SYSINFO-Q and SYSINFO-DA PDU are adequate for a particular BS.
- The "Timeslot Pointer" element in the ACCESS-DEFINE PDU (and in the SYSINFO, SYSINFO-Q and SYSINFO-DA PDU) allows the BS to define those timeslots per TDMA frame that can be used for random access by MSs on this control channel, independently of the downlink channel configuration. For example, the BS may define an extended random access channel, allowing additional random access opportunities. The BS may define an extended random access channel for a common control channel (i.e. MCCH or MCCH-Q or common SCCH) or for an assigned channel.

The ACCESS-ASSIGN PDU then indicates (on a slot-by-slot basis) whether each uplink random access slot is available for common use or only for MSs on an assigned channel. This allows flexible use of the uplink e.g. in the case of an extended random access channel or in the case of minimum mode or if a QAM channel is shared by MSs in common mode and MSs in assigned mode.

- The BS designer should note the default assumptions for an MS when it acquires the main carrier or changes channel within the cell.

### 23.5.1.3.2 BS response to access request

After receiving an MS random access request, the BS should respond with a MAC-RESOURCE PDU indicating successful random access. The response may be sent in the corresponding downlink timeslot in the next TDMA frame (if that slot is appropriate to the downlink control channel). Alternatively the response may be delayed. The WT parameter in the ACCESS-DEFINE PDU defines the time the MS-MAC will wait before deciding to retransmit; see clause 23.5.1.4.

The BS should return the response in a timeslot on the MS's downlink control channel. In the case of a multi-slot downlink control channel, the BS may return the response in any slot of that downlink control channel.

If there is any possible ambiguity about the requesting MS's downlink configuration, the BS may return the response in more than one downlink slot.

If the BS is ready to return an LLC response or a layer 3 message (e.g. D-CALL PROCEEDING or D-CONNECT ACKNOWLEDGE) to the requesting MS at the time when it sends the MAC-RESOURCE response PDU, then it may include a TM-SDU in the MAC-RESOURCE PDU. Otherwise it should send a dedicated MAC response PDU.

### 23.5.1.3.3 Reserving subslots on uplink

During an access frame, the BS may transmit PDUs that demand a response from a specific MS (e.g. the D-SETUP PDU). To allow the MS to respond without making a random access, the BS may reserve a subslot or slot(s) for the response. The ACCESS-ASSIGN PDU indicates which subslots are reserved and therefore not available for random access. The MS for which a subslot or slot(s) are reserved shall be informed in the downlink signalling channel (see clause 23.5.2).

The ACCESS-ASSIGN PDU also indicates subslots that are available for common use for linearization (and therefore not available for random access).

## 23.5.1.4 MS-MAC random access protocol

### 23.5.1.4.0 General

The general random access procedure is described in clauses 23.5.1.4.1 to 23.5.1.4.9; this procedure covers normal operation on one  $\pi/4$ -DQPSK control channel (common, assigned or multi-slot). Then any variations in operation for different channel configurations are described in clauses 23.5.1.4.10 to 23.5.1.4.18. For example, random access operation on a QAM control channel is described in clause 23.5.1.4.18.

### 23.5.1.4.1 Reception of ACCESS-DEFINE PDU

The MS-MAC shall continuously receive the downlink control channel, looking for ACCESS-DEFINE PDUs (within the constraints of the energy economy or dual watch regime or the napping procedures, and the cell reselection procedures, and linearization and transmission requirements). The downlink slot(s) appropriate to this control channel are known from the SYSINFO PDU (BNCH) or from the "Timeslot Assigned" element in the MAC-RESOURCE or MAC-END PDU that sent the MS to the channel. An ACCESS-DEFINE PDU defines access restrictions and access parameters for one access code.

On receipt of an ACCESS-DEFINE PDU, the MS-MAC shall note the minimum valid PDU priority for the access code; also, if included, the MS-MAC shall note the eligible subscriber classes or group address. If the ACCESS-DEFINE PDU does not include a "subscriber class bit map" element, the MS-MAC shall assume that there is no subscriber class restriction. If the ACCESS-DEFINE PDU does not include a "GSSI" element, the MS-MAC shall assume that there is no address restriction.

The MS-MAC shall note the ALOHA parameters (IMM, WT, Nu, frame-length factor). It shall also note from element "Timeslot Pointer" which uplink slots are potentially available for random access on this control channel i.e. the valid pattern for attempting to receive and decode the AACH for access invitations. If Nu is set to 0 in the ACCESS-DEFINE PDU, this indicates that the access code is not available for use.

The MS-MAC shall comply with the received ACCESS-DEFINE parameters for random access attempts on this access code and control channel. Each parameter set shall remain valid until updated by a subsequent ACCESS-DEFINE PDU for this access code and with the same setting of the "Common or assigned control channel flag", received on this downlink control channel.

NOTE 1: A subsequent ACCESS-DEFINE PDU for this access code overwrites the previous definition even if the addressing mechanism (i.e. subscriber class bit map, GSSI or neither) is not the same.

An MS on its common control channel shall ignore any received ACCESS-DEFINE PDUs containing "Common or assigned control channel flag" = 1 (i.e. assigned). Similarly, an MS on a channel assigned for SCCH or for a circuit mode call shall ignore any received ACCESS-DEFINE PDUs containing "Common or assigned control channel flag" = 0 (i.e. common).

NOTE 2: A  $\pi/4$ -DQPSK common control channel is the MCCH or a  $\pi/4$ -DQPSK common SCCH.

NOTE 3: The "Timeslot Pointer" element may give a bit map of the appropriate timeslots for the random access channel for this control channel, or it may be set to 0000<sub>2</sub> (i.e. same as downlink slot assignment). The latter means:

- slot 1 if the MS is on the MCCH;
- the appropriate slot for this MS when common SCCHs are in use; or

- the same timeslot number(s) as for the "Timeslot Assigned" element from the MAC-RESOURCE or MAC-END PDU in the case of an assigned channel.

#### 23.5.1.4.2 Reception of ACCESS-ASSIGN PDU

If the MS-MAC wishes to send a random access message, and knows a valid access code for the message, it shall attempt to decode the appropriate downlink AACH which contains the ACCESS-ASSIGN PDU. The MS should look for the AACH in all the slots defined by element "Timeslot Pointer" from the ACCESS-DEFINE PDU (or the default value from the SYSINFO PDU), in all frames 1 to 18.

If an ACCESS-ASSIGN PDU contains two access field elements then "Access field 1" conveys access rights to subslot 1 in the corresponding uplink slot, i.e. the same-numbered uplink timeslot of that TDMA frame. "Access field 2" conveys independent access rights to subslot 2 in the uplink slot.

If an ACCESS-ASSIGN PDU contains only one access field, this conveys access rights to both subslots of the corresponding uplink slot as follows:

- a) the same access code shall be assumed for both subslots;
- b) when the access field indicates "Reserved subslot", it shall be assumed that both subslots are reserved;
- c) when the access field indicates "CLCH(-Q) subslot", it shall be assumed that subslot 1 may be used for linearization, and that subslot 2 is reserved;
- d) when the access field indicates "Ongoing frame", it shall be assumed that ongoing frame applies to both subslots;
- e) when the access field indicates a frame marker base frame-length of  $\geq 1$  subslots, it shall be assumed that the frame marker base frame-length applies to subslot 1, and that "Ongoing frame" applies to subslot 2.

If an ACCESS-ASSIGN PDU contains no access field (i.e. traffic on uplink) then both the corresponding uplink subslots shall be regarded as reserved.

If an MS on its common control channel receives an ACCESS-ASSIGN PDU indicating that the uplink slot is designated as "Assigned only", then both the corresponding uplink subslots shall be regarded as reserved.

If an MS on an assigned channel (assigned for SCCH or for a circuit mode call) receives an ACCESS-ASSIGN PDU indicating that the uplink slot is designated as "Common only", then both the corresponding uplink subslots shall be regarded as reserved.

If the AACH is un-decodeable then both the corresponding uplink subslots shall be regarded as reserved.

NOTE: As defined in clause 9, the start of the TDMA frame (and multiframe and hyperframe) on the uplink is delayed by a fixed period of two timeslots from the start of the TDMA frame (or multiframe or hyperframe) on the downlink. So the ACCESS-ASSIGN PDU in a downlink slot conveys access rights to the corresponding uplink slot, which is two slots later.

#### 23.5.1.4.3 Initiating a random access

The MS shall only make one random access attempt at a time, per control channel. A random access attempt refers to the period from initiation of the random access procedure until a response is received or the procedure is abandoned.

When the MS has individually addressed unscheduled signalling messages to send, as indicated by the DATA-IN-BUFFER signal from the LLC, the MS-MAC may initiate the random access procedure if it:

- a) does not have a reserved subslot or slot(s) already granted for this address on this control channel; and
- b) has not already indicated to the BS that it has a signalling requirement for this address on this control channel (by asking for a reserved subslot or slot(s)).

NOTE 1: The ISSI and its associated ASSI are equivalent for the purposes of the slot granting procedure (so the MS should use any subslot or slot(s) granted on its ISSI for messages sent with its ASSI, or vice versa). Similarly, an event label and its corresponding address are equivalent for the purposes of the slot granting procedure. Also, a newly assigned ASSI is equivalent to the replaced ASSI or USSI for the purposes of the slot granting procedure.

NOTE 2: As defined above, the MS is permitted to initiate the random access procedure if the MS has individually addressed unscheduled signalling messages to send and criteria a) and b) are satisfied. This applies either if the MS has only unscheduled signalling messages to send or if it has both unscheduled and fully scheduled signalling messages to send. However, in the latter case, the MS may choose to delay initiation of the random access procedure in some cases. For example, it could decide to delay initiation of the random access procedure if the lowest value of the maximum schedule interval for the fully scheduled data (as indicated by the DATA-IN-BUFFER signal from the LLC) is small.

NOTE 3: If the MS has only fully scheduled signalling messages to send, it is not permitted to initiate the random access procedure unless the criteria in clause 23.5.2.4.2 are satisfied.

Also, the MS-MAC may initiate the random access procedure if it does not have a reserved subslot or slot(s) already granted for this address on this control channel, and the LLC indicates that a new emergency unscheduled message has just been received from layer 3, as indicated by the PDU priority parameter set to 7 in the DATA-IN-BUFFER signal.

NOTE 4: This exception allows the MS-MAC to cut short the reserved access waiting time-out T.206 in case of emergency; see clause 23.5.2.4.1. The MS may then send the emergency message by random access.

If the MS-MAC was in the process of sending a fragmented message at the time when it decides to cut short the reserved access waiting time-out T.206, it should discard the partially sent TM-SDU.

When the MS has individually addressed unscheduled signalling messages to send, and has indicated a signalling requirement for this address on this control channel, and does not have a reserved subslot or slot(s) granted for this address on this control channel, the MS-MAC may initiate the random access procedure if the criteria in clause 23.5.2.4.1 are satisfied.

Also, if the MS supports data priority, and has individually addressed signalling messages to send, and has indicated a signalling requirement for this address on this control channel, and does not have a reserved subslot or slot(s) granted for this address on this control channel, the MS-MAC may initiate the random access procedure if the criteria in clause 23.4.7.5.2 or clause 23.4.7.5.3 are satisfied.

When the MS has fully scheduled signalling messages to send, the MS-MAC may initiate the random access procedure if the criteria in clause 23.5.2.4.2 are satisfied.

The random access request shall be sent using the MAC-ACCESS PDU, fitting within a single subslot on the uplink (SCH/HU) and containing a TM-SDU or first fragment if appropriate. Any TM-SDU to be sent, or TM-SDUs if using association, are received from the LLC in the TMA-UNITDATA request primitive.

If the MS has any further signalling to send for this address on this control channel, the MS-MAC shall include a request for reserved capacity in the MAC-ACCESS PDU.

When the MS-MAC is required to initiate a random access, it shall comply with the access parameters. If the access request is not valid for any of the current access codes (as specified in clauses 23.5.1.4.1 and 23.5.1.4.4), the MS-MAC may immediately abandon the random access attempt, reporting the failure to the LLC using the TMA-REPORT indication primitive.

#### 23.5.1.4.4 Checking for appropriate access code

When the MS-MAC wishes to send a non-emergency message, it shall not use a subslot designated for a particular access code unless the following criteria are all satisfied:

- a) the PDU priority, as supplied in the TMA-UNITDATA request primitive, is equal to or higher than the minimum PDU priority for this access code;
- b) if subscriber class is restricted for this access code: the subscriber class information, as supplied in the TMA-UNITDATA request primitive, is eligible for this access code;
- c) if address is restricted for this access code: the designated GSSI is one of the MS's valid group addresses.

For an emergency message, the same criteria shall apply for access codes B, C and D. However, the MS may use access code A for an emergency message without checking the above criteria.

For a message sent when the MS does not have subscriber class information for this network, criterion b) need not be checked.

NOTE 1: In criterion b), the eligibility for subscriber class requires that, for at least one class, the class is invited by the ACCESS-DEFINE PDU (i.e. there is a "1" in the appropriate position) and the MS belongs to that class.

NOTE 2: The message is an "emergency message" if the PDU priority parameter in the TMA-UNITDATA request primitive indicated the highest priority, i.e. 7.

NOTE 3: The exemption from checking criterion b) when the MS does not have subscriber class information for this network applies during migration. It applies also on the MS's home network if the MS does not have subscriber class information on this network and did not receive subscriber class information at subscription.

#### 23.5.1.4.5 First try procedure

There is a special procedure for the first random access transmission.

The MS-MAC shall transmit its random access request in the first uplink slot in which one or both subslots are valid access opportunities (i.e. slot corresponds to element "Timeslot Pointer" and has an appropriate common/assigned designation, and subslot has an appropriate access code and is not reserved nor assigned for linearization) if:

- a) it is an emergency message; or
- b) parameter IMM = 15; or
- c)  $1 \leq IMM \leq 14$ , and the valid access opportunity occurs within the IMM TDMA frames following the initiation of the random access procedure.

If both the subslots in the uplink slot are valid access opportunities, the MS-MAC shall choose one of the two subslots randomly. This rule applies only to this first try procedure.

If the above conditions are not met, then the MS-MAC shall choose a subslot from a new access frame (see clause 23.5.1.4.6).

If a complete TM-SDU is contained within the MAC-ACCESS PDU, then the MS-MAC shall report to the LLC when the first random access transmission has been sent using the TMA-REPORT indication primitive.

#### 23.5.1.4.6 Choosing from a new access frame

An MS-MAC that requires to select a subslot from a new access frame shall wait for a suitable access frame marker i.e. an ACCESS-ASSIGN PDU in a slot corresponding to element "Timeslot Pointer" with an access field that contains:

- a frame marker ("Base Frame-length" of  $\geq 1$  subslots); and
- an appropriate uplink slot designation (common/assigned); and
- an appropriate access code (as defined in clause 23.5.1.4.4),

with the most recently received access code parameters enforced at this time.

The MS-MAC shall then select a subslot randomly from the specified access frame. That is, it shall choose a subslot randomly between 1 and "Frame-length" using a uniform distribution, where:

```
if the "frame-length factor" for this access code = 0
then Frame-length = 1 × Base Frame-length
else Frame-length = 4 × Base Frame-length.
```

The MS-MAC shall transmit its access request in the chosen subslot, unless the random access attempt is abandoned (see clause 23.5.1.4.9).

#### 23.5.1.4.7 Counting subslots in an access frame

The uplink subslot corresponding to the frame marker access field is defined as the first subslot in the access frame.

When counting further access subslots to its chosen subslot in the access frame, the MS-MAC shall count a subslot only if:

- a) it was indicated by element "Timeslot Pointer" in the ACCESS-DEFINE PDU (or, for access code A, in the SYSINFO PDU if the default definition is still valid); and
- b) the corresponding ACCESS-ASSIGN PDU is received; and
- c) the uplink slot designation (common/assigned) is appropriate for this control channel; and
- d) the subslot is marked with the appropriate access code, i.e. the access code used when choosing from the access frame; and
- e) the subslot is not designated as reserved or assigned for linearization.

NOTE: Subslots for this code designated as "ongoing frame" are counted, and also subslots starting new access frames; a new access frame marker does not alter a subslot choice already made.

#### 23.5.1.4.8 Re-try procedure

After sending an access request, the MS-MAC shall wait for a response from the BS, i.e. a MAC-RESOURCE PDU on the downlink control channel, containing the same address as in the access request and with the "random access flag" indicating successful random access. If a complete TM-SDU was contained within the MAC-ACCESS PDU, the MS-MAC shall report the success to the LLC using the TMA-REPORT indication primitive. Then, if the received MAC-RESOURCE PDU contains a TM-SDU, the MS-MAC shall deliver that TM-SDU to the LLC using the TMA-UNITDATA indication primitive.

The MS-MAC shall look for the response in all downlink slots appropriate to this downlink control channel, as indicated by the SYSINFO PDU or by the MAC-RESOURCE or MAC-END PDU that sent the MS to the channel. The first potential slot in which the response may be received is the corresponding downlink slot in the next TDMA frame, i.e. the same timeslot number as the request slot, if that slot is appropriate to the downlink control channel. This allows the MS approximately one timeslot duration for switching from transmission to reception.

If a response is not received within the WT downlink signalling opportunities after transmission of its access request, the MS-MAC shall assume that the transmission has failed. Then it shall either:

- a) abandon its random access attempt (see clause 23.5.1.4.9 point a); or
- b) select a further subslot randomly from a new access frame, as in clause 23.5.1.4.6, and using a frame marker ACCESS-ASSIGN PDU received in or after the WT<sup>th</sup> downlink signalling opportunity following the unsuccessful access request. However, if the MS-MAC receives a response before sending a repeat message, it shall accept the response and not retransmit.

When counting slots (i.e. downlink signalling opportunities) for time-out WT, the MS-MAC shall count only one slot per TDMA frame, namely the downlink slot with the same timeslot number as the request slot or, if that slot is not appropriate to the downlink control channel, then the next slot that is appropriate to the downlink control channel.

On an assigned channel, the MS-MAC shall count the downlink slot only if it is available for control. Downlink slots in frames 1 to 17 for which the ACCESS-ASSIGN PDU (or last received ACCESS-ASSIGN PDU in frames 1 to 17) indicates downlink user traffic should not be counted in the time-out WT. However, the BS may choose to send the response by stealing from the downlink TCH.

NOTE 1: Downlink user traffic in frames 1 to 17 is indicated by Header  $\neq 00_2$  and downlink usage marker  $\geq 000100_2$ .

NOTE 2: The above procedure allows for possible cases of independent allocation of uplink and downlink.

NOTE 3: As defined above, the MS looks for a response in all downlink slots appropriate to that channel. However a maximum of one slot per TDMA frame is counted for time-out WT. This is equivalent to the method for timers T.202 and T.206, and some LLC timers. It contrasts with the method for counting uplink opportunities for the granting delay for reserved access, when all slots on a multi-slot channel are counted; and with the method for counting access subslots in an access frame, when all appropriate subslots are counted.

#### 23.5.1.4.9 Abandoning random access attempt

The MS-MAC shall cease attempting random access if it receives a response from the BS, as described in clause 23.5.1.4.8, or if any of the following occurs:

- a) The MS-MAC has sent the current maximum permitted number of random access transmissions without receiving a response; the maximum number of transmissions is  $N_u$  for a message with PDU priority 0 to 6, or  $2 \times N_u$  for a message with PDU priority 7. The failure shall be reported to the LLC using the TMA-REPORT indication primitive.
- b) A time T.205 has elapsed since initiation of the random access procedure. The failure shall be reported to the LLC.
- c) The MS-MAC receives a TMA-CANCEL request primitive from the LLC, cancelling transmission of this message. The MS-MAC shall abandon the random access attempt whether or not it has sent any transmissions, reporting the state of transmission to the LLC.
- d) The MS-MAC receives a MAC-RESOURCE (or MAC-END or MAC-D-BLCK) PDU that does not indicate successful random access but grants a reserved subslot or slot(s) for this address. The MS-MAC shall send a PDU (or PDUs) in the reserved capacity, e.g. its own request and/or the message demanded by the BS. If the MS has any further signalling ready to send for this address on this control channel, the MS-MAC shall include the "reservation requirement" element in its transmission.

If a complete TM-SDU is transmitted, the MS-MAC shall report to the LLC that the message has been sent by reserved access.

Also, if the access request becomes ineligible for the current definition of the access codes, the MS-MAC may abandon the random access attempt, reporting the failure to the LLC.

If the MS-MAC abandons a random access attempt without having received a response from the BS, it shall not initiate any new random access attempt until any ongoing WT timer from the last request has expired.

#### 23.5.1.4.10 Random access operation after acquiring main carrier

The MS-MAC shall make the following assumptions about the random access parameters on first acquiring a CA main carrier or receiving a channel allocation for a CA new cell.

If the MS-MAC has received the "default definition for access code A" element in the SYSINFO PDU then it shall assume the most recently received SYSINFO parameters for access code A, and with no MAC subscriber class restriction or address restriction, until it receives an ACCESS-DEFINE PDU for access code A. Otherwise it shall not use access code A until it receives either the SYSINFO default definition for access code A or an ACCESS-DEFINE PDU for access code A.

The MS-MAC shall not use access code B, C or D until it receives the appropriate ACCESS-DEFINE PDU.

NOTE 1: These parameters apply both to the MCCH and to a  $\pi/4$ -DQPSK common SCCH.

There is no time limit on the validity of use of the SYSINFO parameters, since some BSs may choose never to send the ACCESS-DEFINE PDU, relying solely on the SYSINFO default definition for access code A. Until receipt of a "common" ACCESS-DEFINE PDU for access code A, the MS shall assume the most recently received SYSINFO parameters. After receipt of a "common" ACCESS-DEFINE PDU for access code A, the MS shall ignore any access parameters received in SYSINFO PDUs, reverting to the procedure in clause 23.5.1.4.1.

NOTE 2: The validity of use of the SYSINFO parameters on the MCCH or a  $\pi/4$ -DQPSK common SCCH is not affected by receipt of an ACCESS-DEFINE PDU with "Common or assigned control channel flag" = 1 (i.e. assigned). Receipt of an "assigned" ACCESS-DEFINE PDU for access code A while the MS is on the MCCH or a  $\pi/4$ -DQPSK common SCCH does not affect the validity of the SYSINFO parameters. Receipt of an "assigned" ACCESS-DEFINE PDU for access code A while the MS is on an assigned channel over-rides the SYSINFO definition while the MS is on that assigned channel, but does not affect operation when the MS returns to the MCCH or to a  $\pi/4$ -DQPSK common SCCH.

NOTE 3: If the MS receives a channel allocation for an assigned channel on a CA new cell, it should apply a combination of the procedures for random access operation after acquiring a CA main carrier and then random access operation on a new channel. So, for the purposes of the random access parameters, the MS should treat the channel allocation for the type 1 announced cell reselection (actually received on an assigned channel on the old cell) as if it had been received on the main carrier of the new cell.

EXAMPLE: If the MS receives a channel allocation for a  $\pi/4$ -DQPSK assigned channel on a CA new cell then, when clause 23.5.1.4.11 b) says that the MS-MAC assumes that "the other parameters are equal to those on the old channel except that ..." the MS-MAC should actually assume that "the other parameters are equal to those on the main carrier of the CA new cell except that ...".

#### 23.5.1.4.11 Random access operation on a new channel

When an MS is sent to a new channel within the cell, it shall make the following assumptions about the random access parameters, until updated by ACCESS-DEFINE PDUs or the SYSINFO definition.

- a) When changing channel to the MCCH or to a  $\pi/4$ -DQPSK common SCCH, a CA MS-MAC shall assume that all random access parameters except the "Timeslot Pointer" are equal to those used when the MS-MAC last received either the MCCH or a  $\pi/4$ -DQPSK common SCCH (parameters as received in SYSINFO and/or ACCESS-DEFINE PDUs). This rule applies both when the BS has changed the number of common SCCHs in use and when the MS-MAC returns from an assigned channel.

The MS-MAC shall assume that the random access channel uses the same timeslot as the current downlink assignment.

- b) For an assigned channel (either for SCCH or for a circuit mode call):
- For the "Timeslot Pointer", the MS-MAC shall assume the same timeslot number(s) as for the "Timeslot Assigned" from the MAC-RESOURCE or MAC-END PDU.
  - The MS-MAC shall assume that the other parameters are equal to those on the old channel except that, for access code A, the MS-MAC shall assume "Frame-length Factor" = 0, "Minimum PDU Priority" = 000<sub>2</sub> and no subscriber class restriction or address restriction.

The MS-MAC may continue an ongoing random access attempt on the new channel, but shall choose a subslot from a new access frame using an appropriate frame marker received on the new channel.

The random access parameters shall all be updated on receipt of an appropriate ACCESS-DEFINE PDU on that channel. If the MS is on the MCCH or a  $\pi/4$ -DQPSK common SCCH, and is still using the SYSINFO default definition, then the MS shall update the parameters on receipt of a new SYSINFO definition on that channel. If the MS is on an assigned channel, and is still using the SYSINFO default definition on that channel, then the MS shall update the parameters on receipt of a new SYSINFO definition on that channel, except for parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority" for which it shall retain the values given in b) above.

NOTE: Random access information is not included in the SYSINFO-DA PDU when the PDU is sent on a phase modulation channel. Therefore, if a DA MS on a phase modulation channel receives a SYSINFO-DA PDU on that channel, it does not update its random access parameters. (As described above, if a DA MS (or CA MS) is on a phase modulation assigned channel, and is still using the SYSINFO default definition on that channel, it updates its random access parameters on receipt of a new SYSINFO definition on that channel - except for parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority".)

#### 23.5.1.4.12 Random access operation on ACCH

If the MS-MAC wishes to send a random access message on a channel allocated for a circuit mode call, it shall obey the normal procedures but with the following differences.

If the MS is transmitting traffic in frames 1 to 17 and sends a random access request in frame 18 then, when counting downlink slots for waiting time WT, the MS shall count only those slots that it is required to attempt to receive and decode, according to the assigned monitoring pattern(s), and are available for control (see clause 23.5.1.4.8).

NOTE 1: As in clause 23.5.1.4.8, the MS counts a maximum of one slot per TDMA frame for waiting time WT.

NOTE 2: For a multi-slot channel, if the MS is not frequency full duplex, and if the BS assigns monitoring pattern(s) that the MS is not capable of following, then, when counting for waiting time WT, the MS counts only those downlink TDMA frames containing at least one slot that it is able to attempt to receive and decode and that is available for control.

For a multi-slot channel, if the MS is not frequency full duplex, and if there is currently traffic on the downlink, then the MS is not required to transmit a random access request if it would thereby miss downlink traffic. The MS may regard unsuitable uplink subslots as reserved.

Similarly, for a multi-slot channel, if the MS is not frequency full duplex, and if the MS is currently performing a reconstruction of a downlink TM-SDU, then the MS is not required to transmit a random access request if it would thereby cause the reconstruction to fail. The MS may regard unsuitable uplink subslots as reserved. This applies for any multi-slot assigned channel i.e. assigned either for SCCH or for a circuit mode call.

#### 23.5.1.4.13 Random access operation in minimum mode

During minimum mode, the MS-MAC shall follow the defined minimum mode rules for receiving and decoding the downlink for signalling messages - in slot 1 of frames 1 to 17 and in its designated minimum mode slot in frame 18.

When an MS-MAC enters minimum mode, the most recently received access definitions shall apply. If the MS-MAC then receives ACCESS-DEFINE PDUs in the downlink slots that it is required to receive, it shall obey the ACCESS-DEFINE definition for PDUs containing "Common or assigned control channel flag" = 0 (i.e. common); but shall ignore ACCESS-DEFINE PDUs containing "Common or assigned control channel flag" = 1 (i.e. assigned).

If an MS-MAC in minimum mode wishes to send a random access message, the valid pattern for attempting to receive and decode the AACH for access invitations and for counting subslots in an access frame is:

- in frames 1 to 17: the slot(s) defined by the current setting of "timeslot pointer";
- in frame 18: all four slots.

Only those uplink slots marked in the ACCESS-ASSIGN PDU as available for common access are applicable.

The procedures defined in preceding clauses for choosing a subslot for the first and subsequent random access transmissions shall apply. When counting downlink slots for waiting time WT, the MS shall count only its designated minimum mode frame 18 slot. However, the BS may choose to send the response in slot 1 of the assigned channel during frames 2 to 17, either by stealing or within the assigned channel's FACCH (as described in clause 23.3).

NOTE: The above minimum mode procedure applies only to those MSs that are in common control mode and receiving the MCCH. It does not apply to MSs on an assigned channel.

#### 23.5.1.4.14 Random access operation on time-shared control channel

On a time-shared MCCH, the MS-MAC shall follow the defined rules for receiving and decoding the downlink for signalling messages.

If the MS-MAC wishes to send a random access message, it shall obey the normal procedures but with the following differences:

- The rules for attempting to receive and decode the AACH for access invitations and for counting subslots in an access frame (according to element "Timeslot Pointer") shall apply only to the frames reserved for this BS and the common frames.

- For  $1 \leq \text{IMM} \leq 14$ , IMM shall be replaced by:

$\text{IMM} \times 12 / \text{TS-RES}$ , for TS-RES = 1, 2, 3, 4, 6;

$\text{IMM} \times 36 / \text{TS-RES}$ , for TS-RES = 9, 12, 18;

where TS-RES is the number of reserved frames per two multiframes for this BS.

- When counting downlink slots for waiting time WT, the MS shall count only slot 1 of the frames reserved for this BS. However, the BS may choose to send the response in slot 1 of one of the common frames.

For a time-shared common SCCH, "slot 1" in the above shall be replaced by the appropriate slot number on the main carrier.

#### 23.5.1.4.15 Random access operation on CSS channel

On a CSS channel, the MS-MAC shall generally apply the random access procedures defined in the earlier clauses within clause 23.5.1.4 as if the CSS channel were an independent single-slot  $\pi/4$ -DQPSK assigned channel allocated by a specific MAC-RESOURCE or MAC-END PDU with "Timeslot Assigned" =  $1000_2$  (see clause 23.5.4.2.1 d)). So, for example:

- The ALOHA parameters (e.g. IMM, WT, Nu, frame-length factor) received on the CSS downlink channel apply to the CSS random access channel.
- An uplink slot has an appropriate common/assigned designation only if it is designated as "common and assigned" or "assigned only".

However, the following differences shall apply:

- As defined in clause 23.5.4.2.1 d), the MS is only required to receive the CSS channel within the capabilities of that MS.
- If the MS is not frequency full duplex then it is not required to transmit a random access request on the CSS channel if it would thereby miss downlink traffic on an assigned channel or cause a reconstruction on an assigned channel to fail. The MS may regard unsuitable uplink subslots on the CSS channel as reserved.
- After sending a random access request on the CSS channel and not receiving a response within the waiting time WT, the MS may send a retry either on the CSS channel or alternatively on the appropriate assigned channel. Conversely, after sending a random access request on an assigned channel and not receiving a response within the waiting time WT, the MS may send a retry either on the same assigned channel or alternatively on the CSS channel. When the MS wishes to send a retry on a channel, it shall choose a subslot from a new access frame using an appropriate frame marker received on that channel.

When a CA MS obeys a channel allocation with "allocation type" =  $11_2$  (i.e. Replace + CSS channel) where the specified carrier is the MS's main carrier, the MS may, if capable, use the MCCH or the appropriate common SCCH for that MS in addition to the assigned channel (see clause 23.5.4.2.1 d)). Then the same random access procedures shall apply on the MCCH or common SCCH as defined above for a CSS channel except that the MS shall regard the MCCH or common SCCH as a common control channel and therefore an uplink slot has an appropriate common/assigned designation only if it is designated as "common only" or "common and assigned".

#### 23.5.1.4.16 Random access operation with extended random access channel

When an extended random access channel has been defined by the BS, the MS-MAC shall obey the procedures defined in the earlier clauses within clause 23.5.1.4. So, for example:

- The ALOHA parameters (e.g. IMM, WT, Nu, frame-length factor) received on the downlink control channel apply to the extended random access channel defined by element "Timeslot Pointer".
- A subslot is a valid access opportunity if the slot corresponds to element "Timeslot Pointer" for this control channel and has an appropriate common/assigned designation (as defined in c)), and the subslot has an appropriate access code and is not reserved nor assigned for linearization.
- If the MS is on its common control channel then the slot has an appropriate common/assigned designation only if the uplink slot is designated as "common only" or "common and assigned".

If the MS is on an assigned channel then the slot has an appropriate common/assigned designation only if the uplink slot is designated as "common and assigned" or "assigned only".

NOTE 1: Thus the MS applies the same check on the common/assigned designation to all slots of the random access channel defined by element "Timeslot Pointer", irrespective of whether the same-numbered downlink slot is part of the downlink control channel.

- d) When the MS chooses a subslot from a new access frame, it may use a frame marker from any slot corresponding to element "Timeslot Pointer" for this control channel if the slot has an appropriate common/assigned designation (as defined in c)), and the subslot has an appropriate access code.
- e) When counting access subslots to its chosen slot in an access frame, the MS counts all valid access subslots (as defined in b)) i.e. it counts all subslots corresponding to element "Timeslot Pointer" if they have an appropriate common/assigned designation and access code and are not reserved nor assigned for linearization.

Thus all the access subslots corresponding to element "Timeslot Pointer" are equivalent for the purposes of the random access procedure.

When waiting for a response from the BS, the MS looks for the response in the downlink slots appropriate to the downlink control channel (as indicated by the SYSINFO PDU or by the "Timeslot Assigned" element in the MAC-RESOURCE or MAC-END PDU that sent the MS to the channel).

NOTE 2: As in clause 23.5.1.4.8, the MS counts a maximum of one slot per TDMA frame for waiting time WT. See also clauses 23.5.1.4.12, 23.5.1.4.13 and 23.5.1.4.14.

NOTE 3: In the first sentence of clause 23.5.1.4.3 (i.e. where it is specified that the MS makes only one random access attempt at a time, per control channel), the expression "per control channel" refers to the combination of the downlink control channel and the extended random access channel.

#### 23.5.1.4.17 Random access operation on D8PSK channel

If an MS-MAC on a D8PSK channel wishes to send a random access message, it shall obey the procedures defined in the earlier clauses within clause 23.5.1.4.

The following points may be noted:

- a) The BS sends the ACCESS-ASSIGN PDU using  $\pi/4$ -DQPSK modulation, on the AACH.
- b) The MS shall send the random access request using  $\pi/4$ -DQPSK modulation, on SCH/HU.
- c) The BS may send the response MAC-RESOURCE PDU using either a  $\pi/4$ -DQPSK burst or a  $\pi/8$ -D8PSK burst.
- d) If the MS is attempting random access and receives a MAC-RESOURCE (or MAC-END or MAC-D-BLCK) PDU that does not indicate successful random access but grants a reserved subslot or slot(s) for this address (see clause 23.5.1.4.9d), the MS may use either  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK burst(s) when it transmits in the reserved capacity.
- e) In the present document, the only usage of D8PSK channels is for assigned SCCH. Therefore the MS obeys the procedures for an MS on an assigned channel as defined in the earlier clauses within clause 23.5.1.4.

#### 23.5.1.4.18 Random access operation on QAM channel

If an MS-MAC on a QAM channel wishes to send a random access message, it shall obey the procedures defined in the earlier clauses within clause 23.5.1.4, with the following differences:

- 1) The BS sends the ACCESS-ASSIGN PDU on AACH-Q. Therefore, where clauses 23.5.1.4.1 and 23.5.1.4.2 refer to the MS attempting to decode the AACH, the MS shall attempt to decode the AACH-Q instead.
- 2) On a QAM channel, the ACCESS-ASSIGN PDU may not be present within the AACH-Q in some downlink slots; see clause 21.4.7.1. Therefore, for the procedure for reception of the ACCESS-ASSIGN PDU (clause 23.5.1.4.2), there is an additional procedure for the MS:
  - If the ACCESS-ASSIGN PDU is not present within the AACH-Q then both the corresponding uplink subslots shall be regarded as reserved.

NOTE 1: Thus the MS regards both the corresponding uplink subslots as reserved whenever it does not receive the ACCESS-ASSIGN PDU in a downlink slot - either because the AACH-Q is not decodeable or because the ACCESS-ASSIGN PDU is not present within the AACH-Q.

- 3) The MS shall send the random access request using the MAC-ACCESS PDU on SCH-Q/RA (instead of SCH/HU).
- 4) For the first try procedure (clause 23.5.1.4.5) and when counting subslots in an access frame (clause 23.5.1.4.7), the MS shall use the defined procedures for choosing a transmission slot and subslot in time (i.e. subslot 1 or subslot 2). The MS shall then decide which 25 kHz random access uplink RF channel subslot SSN-Q to use for the access request as follows:
  - for a 25 kHz channel:
    - if the defined procedures indicate transmission in subslot 1, the MS shall select SSN-Q = 11;
    - if the defined procedures indicate transmission in subslot 2, the MS shall select SSN-Q = 21;
  - for a 50 kHz channel:
    - if the defined procedures indicate transmission in subslot 1, the MS shall choose SSN-Q randomly from the range 11 to 12 using a uniform distribution;
    - if the defined procedures indicate transmission in subslot 2, the MS shall choose SSN-Q randomly from the range 21 to 22 using a uniform distribution;
  - for a 100 kHz channel:
    - if the defined procedures indicate transmission in subslot 1, the MS shall choose SSN-Q randomly from the range 11 to 14 using a uniform distribution;
    - if the defined procedures indicate transmission in subslot 2, the MS shall choose SSN-Q randomly from the range 21 to 24 using a uniform distribution;
  - for a 150 kHz channel:
    - if the defined procedures indicate transmission in subslot 1, the MS shall choose SSN-Q randomly from the range 11 to 16 using a uniform distribution;
    - if the defined procedures indicate transmission in subslot 2, the MS shall choose SSN-Q randomly from the range 21 to 26 using a uniform distribution.

The MS shall transmit its access request in the selected random access uplink RF channel subslot SSN-Q, unless the random access attempt is abandoned. (See also clauses 9.3.2b and 9.3.6a.)

- 5) On a QAM channel, the BS sends the SYSINFO-Q PDU and/or the SYSINFO-DA PDU on BNCH-Q (instead of sending the SYSINFO PDU on BNCH). The SYSINFO-Q and SYSINFO-DA PDUs contain the "default definition for access code A" element (with the same element structure as in the SYSINFO PDU), though the element is always present in the SYSINFO-Q and SYSINFO-DA PDUs instead of being conditional.

When on a QAM channel:

- CA MSs shall use the information in the SYSINFO-Q PDU;
- DA MSs shall use the information in the SYSINFO-DA PDU.

NOTE 2: When a channel is shared by CA and DA MSs, the values of the "default definition for access code A" element in the SYSINFO-Q and SYSINFO-DA PDUs do not need to be the same.

NOTE 3: The BS should not send the SYSINFO-DA PDU on an assigned channel that is shared by MSs from different DA cells.

- 6) Where clause 23.5.1.4.11 refers to the MS updating the random access parameters on receipt of a new SYSINFO definition on that channel (if it is still using the SYSINFO default definition on that channel), a CA MS on a QAM assigned channel shall instead update the random access parameters on receipt of a new SYSINFO-Q definition on that channel (if it is still using the SYSINFO-Q default definition on that channel). However, the CA MS shall update all the random access parameters on receipt of the new SYSINFO-Q definition (if it is still using the SYSINFO-Q default definition on that channel) - including parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority".

NOTE 4: This contrasts with the procedure in clause 23.5.1.4.11, in which an MS on a  $\pi/4$ -DQPSK (or D8PSK) assigned channel does not update parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority" on receipt of a new SYSINFO definition on that channel.

- 7) The common control channel for a DA MS is the MCCH-Q or a QAM common SCCH. The downlink slot(s) appropriate to a DA MS's common control channel are known from the SYSINFO-DA PDU.
- 8) A DA MS-MAC shall make the following assumptions about the random access parameters on first acquiring a DA main carrier or receiving a channel allocation for a DA new cell.

The MS-MAC shall assume the parameters for the "default definition for access code A" from the most recently received SYSINFO-DA PDU, and with no MAC subscriber class restriction or address restriction, until it receives an ACCESS-DEFINE PDU for access code A.

The MS-MAC shall not use access code B, C or D until it receives the appropriate ACCESS-DEFINE PDU.

NOTE 5: These parameters apply both to the MCCH-Q and to a QAM common SCCH.

There is no time limit on the validity of use of the SYSINFO-DA parameters, since some BSs may choose never to send the ACCESS-DEFINE PDU, relying solely on the SYSINFO-DA default definition for access code A. Until receipt of a "common" ACCESS-DEFINE PDU for access code A, the MS shall assume the most recently received SYSINFO-DA parameters. After receipt of a "common" ACCESS-DEFINE PDU for access code A, the MS shall ignore any access parameters received in SYSINFO-DA PDUs, reverting to the procedure in clause 23.5.1.4.1.

NOTE 6: The validity of use of the SYSINFO-DA parameters on the MCCH-Q or a QAM common SCCH is not affected by receipt of an ACCESS-DEFINE PDU with "Common or assigned control channel flag" = 1 (i.e. assigned). Receipt of an "assigned" ACCESS-DEFINE PDU for access code A while the MS is on the MCCH-Q or a QAM common SCCH does not affect the validity of the SYSINFO-DA parameters. Receipt of an "assigned" ACCESS-DEFINE PDU for access code A while the MS is on an assigned channel over-rides the SYSINFO-DA definition while the MS is on that assigned channel, but does not affect operation when the MS returns to the MCCH-Q or to a QAM common SCCH.

NOTE 7: If the MS receives a channel allocation for an assigned channel on a DA new cell, it should apply a combination of the procedures for random access operation after acquiring a DA main carrier and then random access operation on a new channel. So, for the purposes of the random access parameters, the MS should treat the channel allocation for the type 1 announced cell reselection (actually received on an assigned channel on the old cell) as if it had been received on the main carrier of the DA new cell.

EXAMPLE: If the MS receives a channel allocation for a  $\pi/4$ -DQPSK assigned channel on a DA new cell then, when clause 23.5.1.4.11 b) says that the MS-MAC assumes that "the other parameters are equal to those on the old channel except that ..." the MS-MAC should actually assume that "the other parameters are equal to those on the main carrier of the DA new cell except that ...".

- 9) When a DA MS is sent to a new QAM channel within the cell, it shall make the following assumptions about the random access parameters, until updated by ACCESS-DEFINE PDUs or the SYSINFO-DA definition.
- a) When changing channel to the MCCH-Q or to a QAM common SCCH, a DA MS-MAC shall assume that all random access parameters except the "Timeslot Pointer" are equal to those used when the MS-MAC last received either the MCCH-Q or a QAM common SCCH (parameters as received in SYSINFO-DA and/or ACCESS-DEFINE PDUs). This rule applies both when the BS has changed the number of QAM common SCCHs in use and when the MS-MAC returns from an assigned channel.

The MS-MAC shall assume that the random access channel uses the same timeslot or timeslots as the current downlink assignment.

b) For an assigned channel:

- For the "Timeslot Pointer", the MS-MAC shall assume the same timeslot number(s) as for the "Timeslot Assigned" from the MAC-RESOURCE or MAC-END PDU.
- The MS-MAC shall assume that the other parameters are equal to those on the old channel except that, for access code A, the MS-MAC shall assume "Frame-length Factor" = 0, "Minimum PDU Priority" = 000<sub>2</sub> and no subscriber class restriction or address restriction.

The MS-MAC may continue an ongoing random access attempt on the new channel, but shall choose a subslot from a new access frame using an appropriate frame marker received on the new channel.

The random access parameters shall all be updated on receipt of an appropriate ACCESS-DEFINE PDU on that channel. If the DA MS is on the MCCH-Q or a QAM common SCCH, and is still using the SYSINFO-DA default definition, then the MS shall update the parameters on receipt of a new SYSINFO-DA definition on that channel. If the DA MS is on a QAM assigned channel, and is still using the SYSINFO-DA default definition on that channel, then the MS shall update the parameters on receipt of a new SYSINFO-DA definition on that channel (including parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority").

NOTE 8: This contrasts with the procedure in clause 23.5.1.4.11, in which an MS on a  $\pi/4$ -DQPSK (or D8PSK) assigned channel does not update parameters "Timeslot Pointer", "Frame-length Factor" and "Minimum PDU Priority" on receipt of a new SYSINFO definition on that channel.

10) For DA, when the "Timeslot Pointer" element is set to 0000<sub>2</sub> (i.e. same as downlink slot assignment) on a QAM common control channel, this means:

- slot 1 if the MS is on a one-slot MCCH-Q;
- slots 1 and 2 if the MS is on a two-slot MCCH-Q;
- slots 1, 2 and 3 if the MS is on a three-slot MCCH-Q;
- all four slots if the MS is on a four-slot MCCH-Q;
- the appropriate slot for this MS when QAM common SCCHs are in use.

NOTE 9: When the "Timeslot Pointer" element is set to 0000<sub>2</sub> on a QAM assigned channel, this has the usual meaning i.e. it means the same timeslot number(s) as for the "Timeslot Assigned" element from the MAC-RESOURCE or MAC-END PDU that sent the MS to the channel.

11) For a multi-slot MCCH-Q, if a DA MS is not frequency full duplex, and if the MS is currently performing a reconstruction of a downlink TM-SDU, then the MS is not required to transmit a random access request if it would thereby cause the reconstruction to fail. The MS may regard unsuitable uplink subslots as reserved.

The following points may be noted:

- i) The BS may send the response MAC-RESOURCE PDU using any valid combination of modulation level and coding rate.
- ii) If the MS is attempting random access and receives a MAC-RESOURCE (or MAC-END or MAC-D-BLCK) PDU that does not indicate successful random access but grants a reserved subslot or slot(s) for this address (see clause 23.5.1.4.9d):
  - in the case of a reserved subslot, the MS may use any SCH-Q/HU logical channel appropriate to the bandwidth of the channel when it transmits in a reserved capacity; the MS shall not use SCH-Q/RA in the reserved subslot;
  - in the case of reserved slot(s), the MS may use any SCH-Q/U logical channel appropriate to the bandwidth of the channel when it transmits in the reserved capacity.
- iii) In the present document, the only usage of QAM channels for CA MSs is for assigned SCCH. Therefore a CA MS obeys the procedures for an MS on an assigned channel as defined in the earlier clauses within clause 23.5.1.4, subject to the differences given above.

A DA MS uses QAM channels for assigned SCCH and also for common control. When a DA MS is in assigned mode (having accepted a channel allocation for an assigned channel), it obeys the procedures for an MS on an assigned channel as defined in the earlier clauses within clause 23.5.1.4, subject to the differences given above. When a DA MS is in common mode on its common control channel, it obeys the procedures for an MS on a common control channel as defined in the earlier clauses within clause 23.5.1.4, subject to the differences given above.

## 23.5.2 Reserved access

### 23.5.2.0 General

The random access protocol is generally needed when the MS-MAC wishes to initiate a transaction. However, when an MS-MAC is required to send a solicited message or when it has further signalling to send after the initial access, the BS may reserve slots for that particular MS. Also the MS at SMDCP level may negotiate that the BS will grant reserved capacity with a specified repetition period (and specified accuracy), in order to support an application which requires regular transmissions of bursts of data; this is called scheduled access. When the schedule becomes active, the BS may reserve slots for that MS without the MS needing to use random access (see clauses 23.5.2.6 and 28).

The ACCESS-ASSIGN PDU (on the AACH or AACH-Q) indicates which subslots are reserved and therefore not available for random access by other MSs. The MS-MAC for which a subslot or slot(s) are reserved is informed on the downlink signalling channel, using the MAC-RESOURCE or MAC-END or MAC-D-BLCK PDU.

This clause describes the MS procedures for requesting reserved slots, and the procedures for granting and using reserved slots.

### 23.5.2.1 Reservation requirement

The MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU and MAC-END PDUs on the uplink all allow the MS-MAC to indicate its reservation requirement on this control channel:

- The "reservation requirement" element is an optional element in the MAC-ACCESS, MAC-DATA, MAC-END-HU and MAC-END PDUs, and shall not be included unless the MS has further signalling ready to send.
- The "reservation requirement" element is always included in the MAC-U-BLCK PDU. A specific value is used in the MAC-U-BLCK PDU when the MS has no further signalling to send.

If the MS has further signalling to send for this address on this control channel, the MS-MAC shall include the "reservation requirement" element whenever it transmits an SCH MAC block (i.e. SCH/HU, SCH-P8/HU, SCH-Q/HU, SCH-Q/RA, SCH/F, SCH-P8/F or SCH-Q/U) containing a MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU or MAC-END PDU. If PDU association is used within the MAC block then the "reservation requirement" element shall be included in the last (non-null) PDU in the MAC block.

All MAC-U-BLCK PDUs contain the "reservation requirement" element, irrespective of whether the PDU is sent as the last PDU in the MAC block. (The "reservation requirement" element in a MAC-U-BLCK PDU may indicate "no reservation requirement".) On a QAM channel, the MAC-U-BLCK PDU is shorter than the MAC block in many cases i.e. when using modulation levels higher than 4-QAM or for bandwidths of 100 kHz or more; therefore the "reservation requirement" element may be sent more than once in a MAC block. If the "reservation requirement" element is sent more than once in a MAC block, each instance of the element shall contain the same information.

The "reservation requirement" element shall indicate the MS's estimate of the total capacity required for any further signalling messages (basic link or advanced link, fully scheduled or unscheduled) that it currently has ready to send for this individual address on this control channel:

- The method for the MS-MAC to calculate the required capacity for a fragmented message is described in clause 23.4.2.1.2. The required number of slots depends on the modulation, and the bandwidth and coding rate for QAM, to be used for sending the fragmented message.
- The required capacity for other signalling ready to send on a  $\pi/4$ -DQPSK channel is known from the "amount of data in LLC buffer" parameter in the DATA-IN-BUFFER signal received from the LLC.

- The required capacity for other signalling ready to send on a D8PSK or QAM channel shall be estimated from the information about the amount of data in the LLC buffer per data category, provided in the DATA-IN-BUFFER signal received from the LLC. The required number of slots to send the data depends on both the amount of data and the modulation level (and coding rate for QAM) with which the MS-MAC currently expects to send the data. If there is data for more than one data category, the expected modulation level (and coding rate for QAM) may be different for the different data categories; in this case, the MS-MAC shall estimate the number of slots required at each modulation level (and coding rate for QAM) and shall indicate the total in the "reservation requirement"; see also clause 23.4.9.

NOTE 1: The reservation requirement indicates the total amount of C-plane signalling that the MS wishes to send for this address, irrespective of whether or not the MS has already been granted some future slots.

NOTE 2: The reservation requirement procedure applies only to signalling messages to be sent with an individual address, i.e. the MS's ISSI/ASSI, USSI, SMI or corresponding event label. The BS grants a subslot or slot(s) for the group address when it invokes a low level group presence indication, so the reservation requirement procedure does not apply to group addresses.

NOTE 3: When the MS indicates its reservation requirement, it indicates only the required capacity for the address with which the reservation requirement is sent. The ISSI and its associated ASSI are regarded as equivalent for the purposes of this procedure. Similarly, an event label and its corresponding address are regarded as equivalent for the purposes of this procedure. However, an MS is not permitted to combine any reservation requirements for its SMI with requirements for an SSI (or vice versa), and it is not permitted to combine the reservation requirements for multiple TSI families.

The MS-MAC may indicate a reservation requirement of one subslot, or one or more full slots (as shown in clause 21). The required number of slots is coded in a non-linear format. If the MS's requirement cannot be represented exactly within the defined format, the MS-MAC shall round down to the next lower valid number of slots, except possibly in the case of a MAC-ACCESS or MAC-DATA PDU containing the start of fragmentation. In the case of the start of fragmentation, the reservation requirement shall cover at least the capacity needed for the remainder of the fragmented message.

NOTE 4: The above exception is needed for fragmented messages because the MAC-FRAG PDU cannot include a "reservation requirement" element. Therefore:

- a) if the MS needs 7 slots to send the rest of the TM-SDU, it asks for 8 slots (or more if it has other signalling to send); or
- b) if it needs 9 slots to send the rest of the TM-SDU, it asks for 10 slots (or more); or
- c) if it needs 11 or 12 slots to send the rest of the TM-SDU, it asks for 13 slots (or more); or
- d) if it needs 14 or 15 slots to send the rest of the TM-SDU, it asks for 17 slots (or more).

In all other cases, the "rounding down" rule applies.

Case a) may apply when using  $\pi/4$ -DQPSK or  $\pi/8$ -D8PSK modulation, or 4-QAM rate=1/2 on a 25 or 50 kHz channel, or 16-QAM rate=1/2 on a 25 kHz channel; case b) may apply when using  $\pi/4$ -DQPSK, or 4-QAM rate=1/2 on a 25 kHz channel; cases c) and d) may apply when using 4-QAM rate=1/2 on a 25 kHz channel; see clause 23.4.2.1.2.

## 23.5.2.2 Slot granting

### 23.5.2.2.1 General

The BS may allocate reserved slots to an MS either:

- a) after receiving a request for reserved capacity from the MS; or
- b) when the BS sends the MS a message that requires a response; or
- c) as a result of an active schedule negotiated by the SNDPCP (see clause 23.5.2.6 and clause 28).

The BS shall perform the allocation by including either the "basic slot granting" element or the "multiple slot granting" element in a MAC-RESOURCE or MAC-END PDU sent to the MS, or by including the "basic slot granting" element in a MAC-D-BLCK PDU sent to the MS. The "basic slot granting" and "multiple slot granting" elements are optional elements, included only when required.

In case b), the "basic slot granting" or "multiple slot granting" element will generally be included in the same downlink PDU as the invoking message. For a fragmented downlink TM-SDU, the grant may be included in either the MAC-RESOURCE or the MAC-END PDU.

For the MAC-RESOURCE or MAC-D-BLCK PDU, the slot grant shall refer to the MS addressed in the MAC header. For the MAC-END PDU, the slot grant shall refer to the MS receiving the fragmented message (addressed in the MAC-RESOURCE PDU that contained the first fragment).

There are two forms of the slot granting mechanism: basic slot granting and multiple slot granting:

- Basic slot granting may be used on a  $\pi/4$ -DQPSK, D8PSK or QAM channel. It allows the BS to grant a single subslot, or a single slot, or several slots occupying successive slots on this uplink control channel (except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities).
- Multiple slot granting is available only on a QAM channel. It allows the BS to grant disjoint resources with one slot grant by including multiple explicit instances of the "basic slot granting" element and/or by implicit repetition of the "basic slot granting" element.

#### 23.5.2.2.2 Basic slot granting

The "basic slot granting" element shall be sent by the BS, and understood by the receiving MS-MAC, in the format shown in clause 21. It shall consist of two sub-elements:

##### 1) Capacity allocation:

This element shall indicate the amount of reserved capacity that is granted on the uplink channel. It may indicate either a single subslot or one or more full slots. For a subslot grant, the "capacity allocation" element shall indicate whether the MS shall use the first or second subslot.

##### 2) Granting delay:

This element shall indicate the time of the start of the reservation. It shall have one of the following forms:

- Start in the next uplink slot on this channel (granting delay = 0000<sub>2</sub>). For both single-slot and multi-slot channels, this shall refer to the same-numbered uplink timeslot as the slot containing the slot grant, in the same TDMA frame.
- Delay for the specified number of delay opportunities on this uplink channel (granting delay = 0001<sub>2</sub> to 1101<sub>2</sub>). When counting delay opportunities, the MS shall count successive slots on this uplink channel (including those slots in frame 18 that contain predefined common linearization opportunities). So, for a single-slot channel, the granting delay indicates the delay in TDMA frames; whereas, for a multi-slot channel, there are two or more delay opportunities per TDMA frame (as indicated by the "Timeslot Assigned" element from the MAC-RESOURCE or MAC-END PDU that allocated the channel for a multi-slot assigned channel or as indicated by the SYSINFO-DA PDU for a multi-slot MCCH-Q).
- Start in the first uplink opportunity in the next frame 18 (granting delay = 1110<sub>2</sub>). For a slot grant sent in frame 18, this shall refer to the following frame 18 (after this one).
- Wait for another slot grant (granting delay = 1111<sub>2</sub>). This form does not actually grant slots at this time, but shall serve to restart the MS's timer T.206, thereby preventing the MS-MAC from reverting to random access.

After any granting delay, a grant for one subslot or slot shall apply to the next slot on this uplink channel. For a subslot grant, the "capacity allocation" element shall indicate whether the MS shall use the first or second subslot.

**NOTE:** For a grant of a first subslot or a full slot, it is the responsibility of the BS not to send a granting delay which indicates that the granted capacity is in an uplink slot in frame 18 corresponding to one of the predefined common linearization opportunities. This applies also to the first slot of a grant of more than one slot. If an MS receives a slot granting PDU that does not conform to this limitation then it should ignore the slot grant.

However, the BS may grant the second subslot for reserved access in an uplink slot in frame 18 corresponding to one of the predefined common linearization opportunities.

When several slots are granted, these shall occupy successive slots on this uplink channel (after any granting delay) except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities. As defined in clause 9 and clause 23.4.5, predefined common linearization opportunities in frame 18 occur:

- on a  $\pi/4$ -DQPSK or D8PSK channel: when  $(MN + TN) \bmod 4 = 3$ ;
- on a QAM assigned channel: when  $(MN + TN) \bmod 4 = 3$  and TN is the lowest numbered timeslot of the allocated channel;
- on a one-slot QAM common control channel: when  $(MN + TN) \bmod 4 = 3$  and TN is the common control timeslot;
- on a multi-slot MCCH-Q: when  $(MN + 1) \bmod 4 = 3$  and  $TN = 1$ .

If the MS-MAC receives more than one slot grant for an individual address or valid event label, it shall assume that its current allocation is the combination (i.e. union) of slot grants on this control channel.

Capacity that has been granted cannot be withdrawn by the BS. However, if the MS indicates that it has no further signalling to send then, in some cases, the BS may re-use any remaining granted capacity for another MS (see clause 23.5.2.3.1 for details of when the MS does not use the remainder of the allocation).

### 23.5.2.2.3 Multiple slot granting

Multiple slot granting is available only on a QAM channel. It allows the BS to grant disjoint resources with one slot grant by including multiple explicit instances of the "basic slot granting" element and/or by implicit repetition of the "basic slot granting" element:

- it allows multiple instances of the "basic slot granting" element to be included in one slot grant;
- it also provides an implicit repeat mechanism for each instance of the "basic slot granting" element, to allow a patterned repetition of resources to be granted with one "basic slot granting" element.

The "multiple slot granting" element shall be sent by the BS, and understood by the receiving MS-MAC, in the format shown in clause 21. The "multiple slot granting" element contains a number (1 to 7) of slot granting sets where each set comprises:

- an 8-bit "basic slot granting" element; and
- a 4-bit implicit repeat count (IRC) for this "basic slot granting" element.

The receiving MS-MAC shall regard each slot granting set as if it had received  $(IRC + 1)$  instances of the 8-bit "basic slot granting" element.

**EXAMPLE:** For a multiple slot grant comprising two slot granting sets, where the first slot granting set included an implicit repeat count of 3 and the second slot granting set included an implicit repeat count of 2, the MS regards the multiple slot grant as if it had received 7 basic slot granting elements in the following order:

- first basic slot granting element;
- implicit repetition of first basic slot granting element;
- implicit repetition of first basic slot granting element;
- implicit repetition of first basic slot granting element;
- first basic slot granting element;
- implicit repetition of first basic slot granting element;
- implicit repetition of first basic slot granting element;

- second basic slot granting element;
- implicit repetition of second basic slot granting element;
- implicit repetition of second basic slot granting element.

The MS-MAC shall process each of the basic slot granting elements (either included explicitly or implied by the implicit repeat count). As in clause 23.5.2.2.2, the basic slot granting element shall consist of two sub-elements:

1) Capacity allocation:

This element shall indicate the amount of reserved capacity that is granted on the uplink channel. It may indicate either a single subslot or one or more full slots. For a subslot grant, the "capacity allocation" element shall indicate whether the MS shall use the first or second subslot.

2) Granting delay:

This element shall indicate the time of the start of the reservation.

Use of granting delay = 1111<sub>2</sub> is not valid in a multiple slot grant.

The granting delay in the first basic slot granting element shall be counted from the downlink slot containing the slot grant, as defined in clause 23.5.2.2.2.

The granting delay in the second and subsequent implicit or explicit basic slot granting elements (including implicit repetitions of the first basic slot granting element) shall be counted from the end of the grant defined by the previous implicit or explicit basic slot granting element. The granting delay shall have one of the following forms:

- a) Start in the next uplink slot on this channel (granting delay = 0000<sub>2</sub>). For both single-slot and multi-slot channels, this shall refer to the next uplink timeslot on this uplink channel following the end of the previous slot grant.
- b) Delay for the specified number of delay opportunities on this uplink channel (granting delay = 0001<sub>2</sub> to 1101<sub>2</sub>). When counting delay opportunities, the MS shall count successive slots on this uplink channel (including those slots in frame 18 that contain predefined common linearization opportunities).
- c) Start in the first uplink opportunity in the next frame 18 (granting delay = 1110<sub>2</sub>). If last slot or subslot of the previous slot grant was in frame 18, this shall refer to the following frame 18 (after this one).

After any granting delay, the start of the grant shall apply to the defined slot on this uplink channel with the following exceptions in cases a), b) and c). For a grant of a first subslot or a full slot, if the granting delay nominally indicates that the granted capacity is in an uplink slot in frame 18 corresponding to one of the predefined common linearization opportunities, the MS shall regard the slot grant as being in the following slot on this uplink channel. Similarly, for a grant of more than one slot, if the granting delay nominally indicates that the granted capacity starts in an uplink slot in frame 18 corresponding to one of the predefined common linearization opportunities, the MS shall regard the slot grant as starting in the following slot on this uplink channel.

NOTE 1: This exception does not apply for a grant of the second subslot in a slot for reserved access.

NOTE 2: This exception applies only for second and subsequent implicit or explicit basic slot granting elements (including implicit repetitions of the first slot granting element). For the granting delay in the first basic slot granting element, if granting a first subslot or a full slot, it is the responsibility of the BS not to send a granting delay which indicates that the granted capacity is in an uplink slot in frame 18 corresponding to one of the predefined common linearization opportunities. This applies also to the first slot of a grant of more than one slot. If an MS receives a slot granting PDU that does not conform to this limitation then it should ignore the entire multiple slot grant.

When several slots are granted, these shall occupy successive slots on this uplink channel (after any granting delay) except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities.

If the MS-MAC receives more than one slot grant for an individual address or valid event label, it shall assume that its current allocation is the combination (i.e. union) of slot grants - either basic slot grants or multiple slot grants - on this control channel.

Capacity that has been granted cannot be withdrawn by the BS. However, if the MS indicates that it has no further signalling to send then, in some cases, the BS may re-use any remaining granted capacity for another MS (see clause 23.5.2.3.1 for details of when the MS does not use the remainder of the allocation).

#### 23.5.2.2.4 Slot granting in normal mode

On the MCCH or on a single-slot MCCH-Q, the uplink for reserved access shall occupy only slot 1 of the main carrier. For a capacity allocation of more than one slot, this refers to the use of successive slot 1's except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities.

**EXAMPLE 1:** A three-slot granted allocation on the MCCH or on a single-slot MCCH-Q starting in slot 1 of frame 8 occupies also slot 1 of frames 9 and 10; a four-slot granted allocation starting in slot 1 of frame 16 of multiframe 2 occupies also slot 1 of frames 17, 1 and 2.

For a common SCCH (either a  $\pi/4$ -DQPSK common SCCH or a QAM common SCCH), the same rule shall apply, except with the appropriate slot number on the main carrier.

For a multi-slot MCCH-Q, the uplink for reserved access shall occupy the number of timeslots per TDMA frame indicated by the SYSINFO-DA PDU except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities.

**EXAMPLE 2:** An eight-slot granted allocation on a four-slot MCCH-Q starting in slot 2 of frame 17 of multiframe 5 occupies also slots 3 and 4 of frame 17, slots 1, 2, 3 and 4 of frame 18 and slot 1 of frame 1. An eight-slot granted allocation on a four-slot MCCH-Q starting in slot 2 of frame 17 of multiframe 6 occupies also slots 3 and 4 of frame 17, slots 2, 3 and 4 of frame 18 and slots 1 and 2 of frame 1.

For an assigned SCCH or for an ACCH, the uplink for reserved access shall occupy the timeslot(s) per TDMA frame indicated in the "Timeslot Assigned" element from the MAC-RESOURCE or MAC-END PDU that allocated the channel except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities.

**EXAMPLE 3:** For an assigned SCCH using timeslots 3 and 4:

- a four-slot granted allocation starting in slot 4 of frame 10 occupies also slots 3 and 4 of frame 11 and slot 3 of frame 12;
- on a  $\pi/4$ -DQPSK or D8PSK channel, a six-slot granted allocation starting in slot 3 of frame 17 of multiframe 3 occupies also slot 4 of frame 17, slot 3 of frame 18, slots 3 and 4 of frame 1 and slot 3 of frame 2;
- on a QAM channel, a six-slot granted allocation starting in slot 3 of frame 17 of multiframe 3 occupies also slot 4 of frame 17, slots 3 and 4 of frame 18 and slots 3 and 4 of frame 1;
- on a QAM channel, a six-slot granted allocation starting in slot 3 of frame 17 of multiframe 4 occupies also slot 4 of frame 17, slot 4 of frame 18, slots 3 and 4 of frame 1 and slot 3 of frame 2.

The granting delay is given in terms of the number of opportunities for reserved access on this channel except that, when counting slots for the granting delay, the MS shall include those slots in frame 18 that contain predefined common linearization opportunities. So, for a single-slot channel, the granting delay indicates the delay in TDMA frames; whereas, for a multi-slot channel, there are two or more opportunities per TDMA frame.

**EXAMPLE 4:** On the MCCH or on a single-slot MCCH-Q, for a slot grant sent in frame 15 with a granting delay of  $0100_2$  (i.e. 4 opportunities delay), the granted capacity starts in slot 1 of frame 1 irrespective of the multiframe number. On an assigned SCCH using timeslots 1 and 2, for a slot grant sent in slot 2 of frame 4 with a granting delay of  $0101_2$  (i.e. 5 opportunities delay), the granted capacity starts in slot 1 of frame 7.

**NOTE 1:** The width of the uplink channel for reserved access is the same as the width of the downlink channel. It is defined independently of any extension of the uplink channel for random access.

NOTE 2: The counting of slots for the granting delay is defined in absolute terms given the known number of timeslots per TDMA frame for this channel (and the predefined mapping of common linearization opportunities in frame 18 for a multiple slot grant after the first granting delay). The use of granted slots by the MS is defined in absolute terms given the known number of timeslots per TDMA frame for this channel and the predefined mapping of common linearization opportunities in frame 18. The MS transmits in the granted slots without needing to check the ACCESS-ASSIGN PDU.

For example, on a channel assigned for traffic, the MS should follow the normal methods for counting slots for the granting delay and for using reserved slots. It is the responsibility of the BS to avoid granting slots where another MS may be transmitting traffic. Therefore, when the uplink is in SACCH so that only frame 18 is available for reserved access, the BS should grant only one reserved subslot or slot at a time. (The BS should use either granting delay =  $0000_2$  or  $1110_2$  when sending the slot grant in downlink frame 18 since, for example, if it were to use granting delay =  $0001_2$ , the MS would regard this as an instruction to transmit in frame 1.)

For a basic slot grant or the first basic slot grant in a multiple slot grant, the BS should not grant the first subslot or a first full slot in a frame 18 slot that corresponds to one of the predefined common linearization opportunities. It is also the responsibility of the BS to avoid assigning common linearization subslots in frames 1 to 17 in positions that coincide with granted slots.

Multiple slot granting may be used on a QAM channel (as described in clause 23.5.2.2.3).

EXAMPLE 5: On a QAM assigned channel using timeslots 2, 3 and 4: for a multiple slot grant sent in slot 4 of frame 11 of multiframe 9 and comprising two slot granting sets, where:

- the first slot granting set granted a capacity allocation of two slots with a granting delay of  $0001_2$  (i.e. 1 opportunity delay) and an implicit repeat count of 3; and
- the second slot granting set granted a capacity allocation of five slots with a granting delay of  $0100_2$  (i.e. 4 opportunities delay) and an implicit repeat count of 0;

the granted allocation comprises slots 2 and 3 of frames 12, 13, 14 and 15, slots 2, 3 and 4 of frame 17 and slots 3 and 4 of frame 18 of the current multiframe.

EXAMPLE 6: On a 4-slot QAM channel: for a multiple slot grant sent in slot 2 of frame 3 of any multiframe and comprising three slot granting sets, where:

- the first slot granting set granted a capacity allocation of one slot with a granting delay of  $0000_2$  and an implicit repeat count of 0; and
- the second and third slot granting sets each granted a capacity allocation of one slot with a granting delay of  $0011_2$  (i.e. 3 opportunities delay) and an implicit repeat count of 10;

the granted allocation comprises slot 2 of frames 3 to 18 of the current multiframe and slot 2 of frames 1 to 7 of the next multiframe.

EXAMPLE 7: On a 4-slot QAM channel: for a multiple slot grant sent in slot 2 of frame 11 of multiframe 6 and comprising one slot granting set granting a capacity allocation of one slot with a granting delay of  $0011_2$  (i.e. 3 opportunities delay) and an implicit repeat count of 9, the granted allocation comprises slot 1 of frames 12 to 17 of multiframe 6, slot 2 of frame 18 of multiframe 6 and slot 2 of frames 1 to 3 of multiframe 7. (If the BS wishes the MS to revert back to use of slot 1 after the predefined linearization opportunity, it would need to use more slot granting sets.)

#### 23.5.2.2.5 Slot granting in minimum mode

During minimum mode, if the BS sends a slot granting PDU in an MS's designated minimum mode frame 18 slot, and if that slot is slot 2, 3 or 4, then the BS shall grant only one reserved subslot or slot in that PDU. The reserved subslot or slot shall be granted either in the corresponding uplink slot of that frame 18 (Granting delay =  $0000_2$ ) or in the corresponding uplink slot of the following frame 18 (Granting delay =  $1110_2$ ).

If an MS in minimum mode receives a slot granting PDU in slot 2, 3 or 4 of frame 18 that does not conform to the above limitations, then it shall ignore the slot grant.

NOTE 1: The above limitations apply only to those MSs that are in common control mode, having been receiving the MCCH. They do not apply to MSs on an assigned channel that are using slot 2, 3 or 4 of frame 18 within their ACCH.

NOTE 2: The BS should not grant the first subslot or a full slot in a frame 18 slot that corresponds to one of the predefined common linearization opportunities.

For a slot grant sent in slot 1 of frames 1 to 17, or in slot 1 of frame 18, the BS may make a capacity allocation of more than one slot; this shall then refer to the use of successive uplink slot 1's except that the MS shall jump over those slots in frame 18 that contain predefined common linearization opportunities (i.e. the normal method).

NOTE 3: Multiple slot granting does not apply on a  $\pi/4$ -DQPSK channel. Therefore only basic slot granting is appropriate in minimum mode.

#### 23.5.2.2.6 Slot granting on time-shared control channel

On a time-shared MCCH, the BS may send a slot granting PDU either in one of its own reserved frames or in a common frame. It may grant single subslots, or one or more full slots.

The delay opportunities for counting the granting delay comprise the combination of:

- a) slot 1 of the reserved frames for this BS; and
- b) slot 1 of the common frames.

So the MS shall count successive slot 1's, except that it shall jump over frames that are neither reserved for this BS nor common.

The opportunities for reserved access for using a grant of more than one slot comprise the combination of:

- a) slot 1 of the reserved frames for this BS; and
- b) slot 1 of the common frames,

except that the MS shall jump over those slots in frame 18 for which  $(MN + TN) \bmod 4 = 3$ . So the MS shall use successive slot 1's, except that it shall jump over frames that are neither reserved for this BS nor common and shall jump over those slots in frame 18 for which  $(MN + TN) \bmod 4 = 3$ .

For a time-shared common SCCH, "slot 1" in the above procedure shall be replaced by the appropriate slot number on the main carrier.

NOTE 1: The network is responsible for co-ordinating the use of the uplink on time-sharing cells, to avoid collisions in granted slots.

NOTE 2: Multiple slot granting does not apply on a  $\pi/4$ -DQPSK channel. Therefore only basic slot granting is appropriate on a time-shared control channel.

#### 23.5.2.2.7 BS slot granting operation

The BS may use the facilities for slot granting defined above.

After granting a subslot or slots, the BS should mark the equivalent uplink subslots as "reserved" in the ACCESS-ASSIGN PDU, thereby preventing other MS from sending random accesses. For example, after granting one slot, the BS should mark the two equivalent uplink subslots as "reserved".

If the BS does not receive a message in an individually granted subslot or slot, this may be either because the MS did not receive the downlink message or because the uplink message was corrupted during propagation. The BS may decide to send another slot granting PDU to the MS. In particular, if the BS does not receive a message in the first slot of a grant of several slots, or for a multiple slot grant, it is recommended that the BS sends another slot granting PDU re-granting the remainder of the slots to the same MS (and further slots if appropriate).

For slot granting PDUs, as for all downlink PDUs, the BS should take account of any energy economy or napping or dual watch or part-time reception operation in the MS, sending the PDU in a slot where the MS should be listening.

If the BS wishes to send data to a group, with a low level presence indication from recipient MSs, the BS shall include the group address and a basic slot grant in the MAC PDU that contains the invoking BL-DATA message. The slot grant may be for one subslot, or optionally for one or more full slots, though each MS in the group will use only one subslot; see clause 23.5.2.3.2. The methods whereby the BS detects transmission in the granted subslot (or slots) are left open for choice by system designers, e.g. measurement of received signal strength.

NOTE: Multiple slot granting is not appropriate for the low level presence indication.

The BS may use basic slot granting on a  $\pi/4$ -DQPSK, D8PSK or QAM channel. This allows the BS to grant a single subslot, or a single slot, or several slots occupying successive slots on this uplink control channel (except that the MS jumps over those slots in frame 18 that contain predefined common linearization opportunities).

The BS may use multiple slot granting on a QAM channel. As described in clause 23.5.2.2.3, this allows the BS to grant disjoint resources with one slot grant by including multiple explicit instances of the "basic slot granting" element and/or by using an implicit repeat mechanism for each instance of the "basic slot granting" element.

The implicit repeat mechanism allows a patterned repetition of resources to be granted with one "basic slot granting" element. For example, this may be useful for allocating resources to an MS using scheduled access with a fairly short schedule repetition period (i.e. within the range of the "granting delay" element), or for allocating resources to other MSs sharing the channel with an MS that is using scheduled access.

Use of multiple explicit instances of the "basic slot granting" element may be useful for providing disjoint slot grants that are not based on a patterned repetition of resources.

Use of multiple explicit instances of the "basic slot granting" element in combination with the implicit repeat mechanism may be useful in some cases, for example: at the beginning of a patterned repetition of resources in order to be able to specify a different granting delay for the first capacity allocation, or to extend the effective length of the patterned repetition. It may also be useful if the BS wishes to regain the exact synchronization of a patterned repetition of resources after a predefined common linearization opportunity.

If the MS is not frequency full duplex and does not have fast switching capability, and is operating on a multi-slot channel, it cannot receive the downlink of that multi-slot channel during the elapse time corresponding to one capacity allocation. Similarly, if the MS is not frequency full duplex but does have fast switching capability, and is operating on a four-slot channel or a two-slot channel with alternating timeslots (i.e. slots 1 and 3 or slots 2 and 4), it cannot receive the downlink of the channel during the elapse time corresponding to one capacity allocation. (For multiple slot granting, the MS can receive the downlink of the channel between each instance of capacity allocation for appropriate values of the granting delay.) If the MS cannot receive the downlink of the channel during the elapse time corresponding to a capacity allocation, it cannot receive L2-LINK-FEEDBACK-INFO messages or acknowledgement bit maps from the BS, or make measurements of the downlink channel, during the elapse time corresponding to that capacity allocation; this may affect the MS's link adaptation procedures on a D8PSK or QAM channel (see clause 23.4.9.2). When appropriate, the BS may choose to limit the size of each instance of the capacity allocation on a multi-slot D8PSK or QAM channel. This may apply particularly when the BS perceives that the quality of the link is currently variable such that the MS may wish to adapt its bit rate more frequently than the maximum length of capacity allocation.

### 23.5.2.3 Use of reserved slots

#### 23.5.2.3.1 Individual address or event label

If an MS receives a MAC-RESOURCE PDU or MAC-END PDU containing a "basic slot granting" or "multiple slot granting" element for one of its individual addresses (i.e. its ISSI, ASSI, USSI or SMI) or for a valid individual event label for this control channel, the MS-MAC shall perform the following actions relating to the "basic slot granting" or "multiple slot granting" element; if an MS receives a MAC-D-BLCK PDU containing a "basic slot granting" element for one of its individual addresses or for a valid individual event label for this control channel, the MS-MAC shall perform the following actions relating to the "basic slot granting" element. Other actions may be performed relating to other elements in the MAC header.

For a basic slot grant, the MS-MAC shall inspect the "capacity allocation" and "granting delay" elements and shall record which subslot or slot(s) are allocated to it, as described in clause 23.5.2.2. For a multiple slot grant, the MS-MAC shall inspect the "number of slot granting sets" element, the "capacity allocation" and "granting delay" elements in each "basic slot granting" element and the "implicit repeat count" element(s) and shall record which subslots and/or slots are allocated to it, as described in clause 23.5.2.2.

If the MS has signalling messages to send for this address on this control channel, as known from the DATA-IN-BUFFER signal, then the following procedure applies for each allocated subslot or slot:

- For an allocated subslot, the MS-MAC shall use the appropriate logical channel (SCH/HU on a  $\pi/4$ -DQPSK channel, SCH/HU or SCH-P8/HU on a D8PSK channel, SCH-Q/HU on a QAM channel); it shall send the final fragment of a fragmented TM-SDU, or otherwise a message from the LLC (or messages by association), except in the following case. If the MS has signalling to send but cannot use a subslot, e.g. if it has only full-slot advanced link messages to send, then the MS-MAC shall send a MAC-ACCESS PDU containing the "reservation requirement" element and no TM-SDU.
- For an allocated slot, the MS-MAC shall use the appropriate logical channel (SCH/F on a  $\pi/4$ -DQPSK channel, SCH/F or SCH-P8/F on a D8PSK channel, SCH-Q/U on a QAM channel); it shall send the next fragment of a fragmented TM-SDU, or otherwise a message from the LLC (or messages by association).

After transmitting a complete TM-SDU, or a final fragment, the MS-MAC shall report to the LLC that the message has been sent by reserved access (using the TMA-REPORT indication primitive).

If the MS has no signalling message to send for this address on this control channel then:

- if the MS is on a  $\pi/4$ -DQPSK or D8PSK channel, the MS-MAC should send the Null PDU in the allocated subslot or slot;
- if the MS is on a QAM channel, the MS-MAC shall send either:
  - a) the Null PDU in the allocated subslot or slot; or
  - b) a dummy MAC-ACCESS or MAC-DATA PDU in the allocated subslot or slot i.e. a PDU containing no TM-SDU; the dummy PDU shall be followed by a Null PDU sent by association (except in the case of logical channel SCH-Q/HU25-4H).

On a  $\pi/4$ -DQPSK or D8PSK channel, after sending:

- the Null PDU in an SCH/HU, SCH-P8/HU, SCH/F or SCH-P8/F MAC block; or
- any SCH/HU or SCH-P8/HU MAC block that does not include a "reservation requirement" element; or
- any SCH/F or SCH-P8/F MAC block that contains:
  - a MAC-DATA or MAC-END PDU, and does not include a "reservation requirement" element; or
  - a MAC-U-BLCK PDU indicating no reservation requirement,

the MS shall not use any other capacity that has already been granted for this address on this control channel (whether in one slot granting PDU, or more than one). If the MS receives a further slot granting PDU, and if it still has no signalling messages to send for this address, then it shall send the Null PDU in the first allocated slot or in the allocated subslot, and shall not use the remainder of the allocation.

On a QAM channel, after sending the Null PDU as the only PDU in an SCH-Q/HU or SCH-Q/F MAC block, the MS shall not use any other capacity that has already been granted for this address on this control channel (whether in one slot granting PDU, or more than one, and by either basic slot granting or multiple slot granting). If the MS receives a further slot granting PDU, and if it still has no signalling messages to send for this address, then it may send the Null PDU as the only PDU in the first allocated slot or subslot; if it transmits the Null PDU as the only PDU in the MAC block then it shall not use the remainder of the allocation.

NOTE 1: Therefore, in case a) above, the MS is not permitted to use any other capacity that has already been granted for this address on this control channel. In case b), the MS may use any other capacity that has already been granted for this address on this control channel.

NOTE 2: The ISSI and its associated ASSI are equivalent for the purposes of use of reserved slots (so the MS may use any subslot or slot(s) granted on its ISSI for messages sent with its ASSI, or vice versa). Similarly, an event label and its corresponding address are equivalent for the purposes of use of reserved slots.

Also, a newly assigned ASSI is equivalent to the replaced ASSI or USSI for the purposes of use of reserved slots. Thus, if an MS receives a slot grant on its ASSI then it may use the subslot or slot(s) for messages sent using a new ASSI which replaces that ASSI; and, if a migrating MS receives a slot grant on its USSI while that USSI is still valid then it may use the subslot or slot(s) for messages sent with its ASSI.

However, an MS is not permitted to use a subslot or slot(s) granted on an SSI for messages to be sent with its SMI, or vice versa; also, it is not permitted to use a subslot or slot(s) granted on one SSI for an SSI from another TSI family. These restrictions may possibly be relaxed in future editions of the present document in the case of the final slot of an MS's requested reserved capacity.

NOTE 3: As defined above, a migrating MS that receives a slot grant on its USSI while that USSI is still valid may use the subslot or slot(s) for messages sent with its ASSI. However, there is possible contention on capacity granted on the USSI if multiple migrating MSs with the same USSI are trying to register at the same time. Therefore, when assigning the ASSI, the BS may prefer not to allocate more than one reserved slot on the USSI. This is because any continuation or final fragments of an uplink message sent with the ASSI do not contain addressing information.

### 23.5.2.3.2 Group address

If an MS receives a MAC-RESOURCE PDU or MAC-END PDU or MAC-D-BLCK PDU containing a "basic slot granting" element for one of its valid group addresses, the MS-MAC shall perform the following actions relating to the "basic slot granting" element. Other actions may be performed relating to other elements in the MAC header.

The MS-MAC shall inspect the "capacity allocation" and "granting delay" elements and shall note which subslot or slot(s) are allocated, as described in clause 23.5.2.2. If the MS has a signalling message with this group address to send on this control channel then it shall transmit the message in an uplink subslot using the MAC-ACCESS PDU:

- a) for a subslot grant, it shall use the allocated subslot;
- b) for a grant of one or more slots (G slots), it shall choose one subslot randomly from the grant, i.e. random choice between 1 and  $2 \times G$  using a uniform distribution.

Otherwise, the MS shall not transmit.

NOTE: This procedure is used only for the low level group presence indication (see clauses 22.2.1.3 and 22.3.1.2).

### 23.5.2.4 Reverting to random access

#### 23.5.2.4.1 Reverting to random access for unscheduled signalling messages

If the following criteria are all satisfied then the MS-MAC may initiate the random access procedure (see clause 23.5.1):

- a) the MS-MAC has sent a PDU (MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU or MAC-END) indicating a reservation requirement for this address on this control channel; and
- b) the MS-MAC does not currently have any capacity granted for this address on this control channel; and
- c) a time T.206 has elapsed since:
  - the MS-MAC last sent a PDU on this control channel for this address (i.e. either a MAC-ACCESS, MAC-DATA or MAC-U-BLCK PDU with this address or a MAC-FRAG, MAC-END or MAC-END-HU PDU relating to this address); or
  - the MS-MAC last received a basic slot granting element for this address on this control channel containing the instruction to "Wait for another Slot Grant";

whichever is the later; and

- d) the MS still has unscheduled signalling messages to send for this address on this control channel (as indicated by the DATA-IN-BUFFER signal).

The random access request shall be sent on SCH/HU (for a  $\pi/4$ -DQPSK or D8PSK channel) or on SCH-Q/RA (for a QAM channel) using the MAC-ACCESS PDU, containing a TM-SDU if appropriate. If the MS has any further signalling ready to send for this address on this control channel, the MS-MAC shall include a request for reserved capacity ("reservation requirement" element) in the MAC-ACCESS PDU.

NOTE 1: T.206 is greater than, or equal to, the fragmentation time-out constant T.202. Then, at the time of reverting to random access, the MS-MAC will not be in the process of an uplink fragmentation.

NOTE 2: Time T.206 is counted in downlink signalling opportunities (as defined in annex B). So, for example, in minimum mode the absolute time is 18 times its normal value.

#### 23.5.2.4.2 Reverting to random access for fully scheduled signalling messages

When the MS has fully scheduled signalling messages to send, as indicated by the DATA-IN-BUFFER signal from the LLC, the MS-MAC may initiate the random access procedure if it:

- a) does not currently have any capacity granted for this address on this control channel; and
- b) a time T has elapsed since the MS-MAC last sent a PDU on this control channel for this address (i.e. either a MAC-ACCESS, MAC-DATA or MAC-U-BLCK PDU with this address or a MAC-FRAG, MAC-END or MAC-END-HU PDU relating to this address), where T is defined by:

$$T = \text{Max} ( \text{LMSI}, T.227 )$$

where:

- LMSI is the lowest value of the maximum schedule interval for the fully scheduled data to be sent for this address on this channel (as indicated by the DATA-IN-BUFFER signal from the LLC); and
- T.227 is the value of the minimum scheduled access waiting time-out (see annex B).

The random access request shall be sent on SCH/HU (for a  $\pi/4$ -DQPSK or D8PSK channel) or on SCH-Q/RA (for a QAM channel) using the MAC-ACCESS PDU, containing a TM-SDU if appropriate. If the MS has any further signalling ready to send for this address on this control channel, the MS-MAC shall include a request for reserved capacity ("reservation requirement" element) in the MAC-ACCESS PDU.

NOTE 1: If the MS has both fully scheduled and unscheduled signalling messages to send, it may initiate the random access procedure if the criteria in either this clause or clause 23.5.2.4.1 are satisfied.

NOTE 2: If the MS was in the process of sending a fragmented message at the time when it decides to initiate the random access procedure, it should discard the partially sent TM-SDU. (Alternatively the MS may choose not to initiate the random access procedure in this case.)

#### 23.5.2.5 Example of reservation process

This clause gives an example of the reservation process on a  $\pi/4$ -DQPSK channel.

The MS-MAC has received a TMA-UNITDATA request primitive from the LLC, containing a long TM-SDU (length 512 bits). It uses a MAC-ACCESS PDU for the random access, including the first 56 bits of the TM-SDU and indicating a "reservation requirement" of two slots. The BS sends a MAC-RESOURCE PDU to acknowledge the random access request. The MAC-RESOURCE PDU also includes a "basic slot granting" element, granting the two required slots. The MS-MAC then sends the remainder of the TM-SDU in one MAC-FRAG PDU (264 bits of TM-SDU) and the MAC-END PDU (final 192 bits). The MS has no further signalling to send for this address, so the MAC-END PDU does not contain the "reservation requirement" element, and the MAC block is completed with the Null PDU and fill bits.

## 23.5.2.6 Scheduled access

### 23.5.2.6.1 General

The scheduled access mechanism is provided to support applications which require regular transmissions of bursts of data, such as some types of real-time class and telemetry class data.

The MS at SNDCP level negotiates that the BS will grant a number of reserved slots with the specified schedule repetition period (with the specified accuracy). The number of slots is the BS's estimate of the number of slots needed to send the specified quantity of data.

NOTE: On a D8PSK or QAM channel, the BS's estimate will not always be correct because of the MS's link adaptation procedures. It is the MS's responsibility to request any additional slots needed.

The scheduled access mechanism avoids the need for the MS to make frequent random access attempts in order to request reserved slot(s) for each TL-SDU.

The MAC is responsible for the schedule timing. On request from the SNDCP (via the MLE-CONFIGURE, TL-CONFIGURE and TMC-CONFIGURE request primitives), the MAC in the MS provides a schedule timing service to the higher layers, issuing schedule timing prompts (using the TMC-REPORT indication primitive) at intervals equal to the schedule repetition period. The synchronization of these prompts is initially based on the timing of the TMC-CONFIGURE request primitive. However, the BS may send the L2-SCHEDULE-SYNC message to define the schedule synchronization, in which case the MS-MAC bases the timing of further prompts on that synchronization.

### 23.5.2.6.2 MS operation for sending scheduled messages

When the SNDCP in the MS issues packet data to the lower layers, the "scheduled data status" parameter in the request primitive indicates whether the data should be treated as "not scheduled data", "initial scheduled data" or "scheduled data". When the SNDCP starts sending data using a context for which a schedule has been arranged, and after a substantial gap in the arrival of scheduled data from the service user, the SNDCP instructs the lower layers to treat the first TL-SDU as "initial scheduled data" (see clause 28); further TL-SDUs are then labelled as "scheduled data".

In the DATA-IN-BUFFER signal, the LLC in the MS indicates whether the data in its sending buffer is "fully scheduled" or "unscheduled" or a mixture (see clause 22.3.1.9). For this purpose:

- initial scheduled data is treated as "unscheduled" so that, for example, the MS-MAC may immediately use random access in order to send the data (if it does not have reserved capacity granted for this address on this control channel and has not already indicated a signalling requirement for this address on this control channel);
- scheduled data is treated as "fully scheduled" (except for segment retransmissions), so that the MS-MAC generally waits for a slot grant instead of attempting random access;
- all other types of data and signalling are treated as "unscheduled".

The LLC also indicates the lowest value of the "maximum schedule interval" for all fully scheduled data in the buffer.

NOTE 1: The maximum schedule interval is the sum of the agreed schedule repetition period plus the schedule timing error. It therefore indicates the longest expected time between the granted slots for a particular schedule.

The MS-MAC procedures for fully scheduled messages are similar to the procedures for unscheduled messages except that, if the DATA-IN-BUFFER signal indicates that all the data in the buffer is fully scheduled, the MS-MAC does not attempt random access unless it considers that the schedule agreement has not been honoured (see clauses 23.5.1.4.3 and 23.5.2.4.2).

Otherwise the procedures are similar to the procedures for unscheduled messages; therefore, for example:

- When the MS-MAC transmits a MAC block containing a MAC-ACCESS, MAC-DATA, MAC-U-BLCK, MAC-END-HU or MAC-END PDU, the "reservation requirement" shall include the MS's estimate of the total capacity required for any further signalling messages that it has ready to send for this individual address on this control channel, including fully scheduled messages; see clause 23.5.2.1.

The "reservation requirement" therefore includes the capacity required for the remainder of the agreed quantity of data - including any additional slots needed because the MS may use a lower bit rate on a D8PSK or QAM channel than the BS's estimate assumed. It also covers additional slots needed, for example, if some scheduled SDUs are larger than the size agreed in the schedule, or if the MS has failed to receive slot grant(s) so that it has a backlog of scheduled messages to send, or if the MS also has unscheduled messages ready to send.

- When the MS has been granted a slot or subslot for one of its individual addresses, the MS may use the slot or subslot for any signalling messages (basic link or advanced link, fully scheduled or unscheduled) to be sent for this address on this control channel; see clause 23.5.2.3.1.

When the MS is on a QAM channel, and may have a schedule or schedules in operation (e.g. if the MS has sent scheduled data recently), it should not send the Null PDU as the only PDU in an SCH-Q/HU or SCH-Q/F MAC block if it has already been granted further capacity for this address on this control channel (whether in one slot granting PDU, or more than one, and by either basic slot granting or multiple slot granting).

NOTE 2: This is because the further capacity may be intended for the schedule(s), for data not yet issued by the SNDPCP. If the MS sends the Null PDU as the only PDU in the SCH-Q/HU or SCH-Q/F MAC block, it is not permitted to use that further capacity; see clause 23.5.2.3.1.

### 23.5.2.6.3 Schedule timing in MS

The higher layers may issue a TMC-CONFIGURE request primitive containing the "schedule repetition information" parameter. The "schedule repetition information" parameter contains the following subparameters:

- NSAPI;
- start-stop flag (start or stop);
- schedule repetition period (as a number of timeslot durations).

If the MS-MAC receives a TMC-CONFIGURE request primitive containing the "schedule repetition information" parameter with the "start-stop" flag indicating "start" then it shall start to issue schedule timing prompts at intervals corresponding to the specified schedule repetition period. According to the protocol model, the schedule timing prompt is performed by issuing the TMC-REPORT indication primitive with the "Report" parameter set to "schedule timing prompt". The TMC-REPORT indication primitive shall indicate the NSAPI to which the schedule timing prompt applies.

The MS-MAC shall continue issuing schedule timing prompts for that NSAPI at intervals corresponding to the specified schedule repetition period until:

- it receives a TMC-CONFIGURE request primitive containing schedule repetition information for that NSAPI, with the "start-stop" flag indicating "start" and containing a different value of the schedule repetition period; or
- it receives a TMC-CONFIGURE request primitive containing schedule repetition information for that NSAPI, with the "start-stop" flag indicating "stop".

In the first case, the MS-MAC shall stop issuing schedule timing prompts at intervals corresponding to the old schedule repetition period and shall start issuing schedule timing prompts for that NSAPI at intervals corresponding to the new schedule repetition period. In the second case, the MS-MAC shall stop issuing schedule timing prompts for that NSAPI.

The BS may send the L2-SCHEDULE-SYNC message to define the schedule synchronization. The L2-SCHEDULE-SYNC message contains the NSAPI to which the message applies and a "schedule synchronization point" expressed as a timeslot number, frame number and multiframe number. The MS-MAC shall regard the specified schedule synchronization point as being the uplink slot corresponding to the next occurring instance of that timeslot number, frame number and multiframe number.

If the MS-MAC receives an L2-SCHEDULE-SYNC message while it is issuing schedule timing prompts for that NSAPI then:

- a) if appropriate, the MS-MAC shall continue to issue schedule timing prompts for that NSAPI using its current schedule synchronization until just before the schedule synchronization point specified in the L2-SCHEDULE-SYNC message;

- b) the MS-MAC shall then set its "schedule timing point" for that NSAPI to the schedule synchronization point specified in the L2-SCHEDULE-SYNC message;
- c) the MS-MAC shall then issue a schedule timing prompt for that NSAPI using a timing such that the following criteria 1 and 2 are both satisfied:
  - 1) scheduled data appropriate to this schedule timing prompt shall not be included in the "reservation requirement" or any "data priority blocks" in slots more than one slot before the uplink slot corresponding to the schedule timing point, if the MS transmits in those slots (see note 2); and
  - 2) the MS shall be capable of sending scheduled data appropriate to this schedule timing prompt in the uplink slot corresponding to the schedule timing point, if granted capacity is available at that time for that address on that control channel;
- d) the MS-MAC shall then increment the schedule timing point by the schedule repetition period for that NSAPI.

The MS-MAC shall then continue to perform actions c) and d) (i.e. issuing a schedule timing prompt for that NSAPI, using a timing such that criteria 1 and 2 are both satisfied for the schedule timing point, and then incrementing the schedule timing point by the current schedule repetition period for that NSAPI), until:

- it receives a TMC-CONFIGURE request primitive from the higher layers instructing it to stop issuing schedule timing prompts for that NSAPI; or
- it receives another L2-SCHEDULE-SYNC message for that NSAPI, in which case it shall obey the procedure above for the new schedule synchronization.

NOTE 1: The implementation methods in the MS for achieving the requirements in criteria 1 and 2 are outside the scope of the present document. For example, in an implementation, the MS could choose to hold the scheduled data appropriate to the schedule timing point in a separate buffer in the LLC until just before the schedule timing point instead of holding the scheduled data in the SNDPCP.

NOTE 2: In criterion 1, it is preferable that the MS does not include the scheduled data appropriate to this schedule timing prompt in the "reservation requirement" or "data priority blocks" in any slots before the uplink slot corresponding to the schedule timing point. However, for flexibility of implementation on a multi-slot channel, the MS is not precluded from including the scheduled data in the "reservation requirement" or any "data priority blocks" in the slot immediately preceding the uplink slot corresponding to the schedule timing point (if that slot is appropriate to this uplink control channel and the MS transmits in that slot).

NOTE 3: After receiving an L2-SCHEDULE-SYNC message then, as specified above, the MS-MAC should base the timing of further prompts on that synchronization until it receives a TMC-CONFIGURE request primitive instructing it to stop issuing prompts or it receives another L2-SCHEDULE-SYNC message for that NSAPI. This continues to apply if the MS changes channel and even if it changes cell.

NOTE 4: The procedures in this clause apply to a single address. If the MS has schedules on more than one address then the procedures in this clause apply independently for each address and the L2-SCHEDULE-SYNC message applies only to the schedule for the address on which the message was received.

#### 23.5.2.6.4 BS operation for granting slots for schedule

The BS should start granting scheduled capacity to the MS when its SNDPCP entity receives an SN-DATA or SN-UNITDATA PDU with NSAPI corresponding to an agreed schedule. The BS should then proceed to send slot grants appropriate to the schedule.

The BS designer should choose criteria for when the BS stops sending slot grants appropriate to the schedule, for example, if the PDP context containing the schedule is deactivated, or if the SwMI suspends or cancels the schedule, or if the MS indicates that it is pausing use of the schedule or context, or if the BS repeatedly perceives that the slot grants are not used. In the last two cases, the BS should re-start the slot grants if its SNDPCP entity receives an SN-DATA or SN-UNITDATA PDU with NSAPI corresponding to an agreed schedule.

When the schedule is negotiated at the SNDCP level, the agreement is that the BS will grant a number of slots with the specified schedule repetition period (and with the specified accuracy). The number of slots is the BS's estimate of the number of slots needed to send the specified quantity of data. On a D8PSK or QAM channel, the BS does not know which bit rate the MS will use to send the data. Therefore the BS should estimate the bit rate that the MS will use and then estimate the number of slots for that bit rate. (When the MS uses the slot(s), it will include any reservation requirement for the remainder of the scheduled data and for any other data.)

The "granting delay" element allows a basic slot grant to be delayed by up to 13 delay opportunities:

- On a  $\pi/4$ -DQPSK or D8PSK channel, the BS should not attempt to use the granting delay facility to grant multiple disjoint resources in advance to an MS with a schedule whose period corresponds to less than 13 delay opportunities. This is because, when the MS sends any SCH/HU or SCH-P8/HU MAC block that does not include a "reservation requirement" element or any SCH/F or SCH-P8/F MAC block that contains a MAC-DATA or MAC-END PDU and does not include a "reservation requirement" element or a MAC-U-BLCK PDU indicating no reservation requirement, the MS is not permitted to use any other capacity that has already been granted for this address on this control channel. If the MS used one of the disjoint resources for a scheduled message, it would usually have no further reservation requirement at that time and therefore would not be able to use the other disjoint resources.
- The BS may use multiple slot granting on a QAM channel. As described in clause 23.5.2.2.3, this allows the BS to grant disjoint resources with one slot grant by including multiple explicit instances of the "basic slot granting" element and/or by using an implicit repeat mechanism for each instance of the "basic slot granting" element. Multiple slot granting may be useful for allocating resources to an MS using scheduled access with a fairly short schedule repetition period (i.e. within the range of the "granting delay" element), or for allocating resources to other MSs sharing the channel with an MS that is using scheduled access; see clause 23.5.2.2.7.

#### 23.5.2.6.5 Schedule synchronization by BS

The BS may send the L2-SCHEDULE-SYNC message to an MS in order to synchronize the times at which the SNDCP in the MS issues the scheduled data to the lower layers with the earliest times that the BS intends for the scheduled reserved slots.

NOTE 1: If the BS does not use the L2-SCHEDULE-SYNC message then, for some schedule repetition periods, if the MS also has other data to send while the schedule is running, there are cases when the MS may send its scheduled data with the other data before the reserved slots intended for the scheduled data. If this occurs, the MS may then have no data to send in the reserved slots intended for the scheduled data.

NOTE 2: If the BS uses the L2-SCHEDULE-SYNC message, the BS designer should note that, for flexibility of MS implementation on a multi-slot channel, the MS may include the scheduled data in the "reservation requirement" (and any "data priority blocks") if it transmits in the slot immediately preceding the uplink slot corresponding to the schedule timing point; see clause 23.5.2.6.3.

The BS may send a slot grant with the L2-SCHEDULE-SYNC message, in order to obtain an implicit acknowledgement that the message was received by the MS.

The BS includes a timeslot number, frame number and multiframe number in the L2-SCHEDULE-SYNC message, defining a schedule synchronization point for that NSAPI in the addressed MS. This refers to the next occurring instance of the uplink slot corresponding to that timeslot number, frame number and multiframe number. The BS should send the L2-SCHEDULE-SYNC message at least two TDMA frames before the time corresponding to the intended schedule synchronization point in order to allow for processing delays in the MS (thereby avoiding a possible difference of perception about which hyperframe is intended).

The BS may update the schedule synchronization information for an NSAPI at any time by sending a further L2-SCHEDULE-SYNC message for that NSAPI to the same MS address.

It should be noted that the MS may discard the information received in an L2-SCHEDULE-SYNC message when:

- the PDP context containing the schedule is deactivated; or
- the SwMI suspends or cancels the schedule; or
- the SNDCP in the MS goes into the STANDBY state (see clause 28).

Therefore, in these cases, the BS should send a new L2-SCHEDULE-SYNC message if use of the schedule re-starts and the BS wishes to synchronize the schedule.

### 23.5.3 Cancel request

The LLC may use the TMA-CANCEL request primitive to stop the MAC activities relating to a particular TMA-UNITDATA request primitive. The "handle to the request" references the service request that is to be aborted.

On reception of a TMA-CANCEL request primitive from the LLC, the MS-MAC shall cease all activities related to the service request as identified by its handle. The MS-MAC shall report to the LLC that MAC transmission activities have been aborted, indicating whether:

- a) the TM-SDU has not been completely sent; or
- b) the complete TM-SDU has been sent at least once,

using the TMA-REPORT indication primitive.

NOTE 1: This procedure can be used by the LLC to abort transmission of a message until:

- the complete TM-SDU, or final fragment of a fragmented TM-SDU, has been sent by reserved access or by stealing; or
- the complete TM-SDU has been sent and acknowledged by random access.

After a first transmission of a random access message, the TMA-CANCEL request primitive stops the MS-MAC from sending further random access retries. However, it should be noted that the BS may have received the message.

NOTE 2: The primitive TMA-CANCEL request is used for modelling purposes only.

### 23.5.4 Channel allocation

#### 23.5.4.1 Transmission of channel allocation

The BS may send a channel allocation command either:

- a) to instruct an addressed MS (or MSs) to move from the current channel to another channel; or
- b) to allocate an additional channel for the addressed MS (or MSs). If the MS does not support concurrent MAC services (i.e. if it is not capable of operating on multiple channels) then it may either remain on the current channel and reject the new service or move from the current channel to the new channel and accept the new service.

The BS shall perform the allocation by including the "channel allocation" element in a MAC-RESOURCE or MAC-END PDU. The "channel allocation" element is an optional element, included only when required.

The channel allocation is generally sent in a MAC-RESOURCE PDU. However, if the BS wishes to send channel allocation information with a fragmented message then that information shall be included within the MAC-END PDU and shall not be included within the MAC-RESOURCE PDU.

For the MAC-RESOURCE PDU, the channel allocation shall refer to the MS or MSs addressed in the MAC header. For the MAC-END PDU, the channel allocation shall refer to the MS or MSs receiving the fragmented message (addressed in the MAC-RESOURCE PDU that contained the first fragment).

The channel allocation command may be used to allocate a different channel (timeslot or timeslots) on the current RF carrier or to change both the carrier and timeslot(s) (see clause 21).

When the BS directs the MS to an assigned channel, it shall set element "timeslot assigned" to indicate the appropriate timeslot(s), as a bit map.

If the BS wishes a CA MS to return to the appropriate common control channel (i.e. the MCCH or a  $\pi/4$ -DQPSK common SCCH), it shall set "timeslot assigned" = 0000<sub>2</sub> and indicate the CA main carrier number.

If the BS wishes a DA MS to return to the appropriate common control channel (i.e. the MCCH-Q or a QAM common SCCH), it shall set "timeslot assigned" = 0000<sub>2</sub>. The BS may use an augmented QAM channel allocation, in which case it shall indicate the DA main carrier number. Alternatively, if the BS uses a non-augmented channel allocation, any addressed DA MSs ignore the carrier number and go to the DA main carrier indicated by the last received SYSINFO-DA or SYNC-DA PDU.

The channel allocation command is used to allocate a  $\pi/4$ -DQPSK channel. Alternatively, the channel allocation command may indicate that the allocated channel is a D8PSK channel or a QAM channel. In the case of a QAM channel, the BS indicates whether the bandwidth of the allocated channel is 25 kHz, 50 kHz, 100 kHz or 150 kHz.

The channel allocation command may be used to allocate a channel on the current cell. It may also be used to allocate a channel on another cell e.g. in case of announced cell reselection type 1. The "cell change flag" shall indicate whether the channel allocation is for another cell. For a channel allocation directing an MS to another cell, the bit map in element "timeslot assigned" shall refer to the timeslot numbering on the new cell.

NOTE 1: The channel allocation method is used for directing addressed MSs to a specified channel. In addition, the broadcast message SYSINFO PDU or SYSINFO-DA PDU may cause an MS to move from one common control channel to another, e.g. when the number of common SCCHs is changed (see clause 23.3). For such a move, the same endpoint identifier applies, and the same service to the LLC is maintained for basic link and for any advanced link(s).

NOTE 2: When the BS assigns a channel for a circuit mode call, the resource allocation should correspond to that required for the network layer basic service information for the call (see clause 14). For example, the assigned channel should be a  $\pi/4$ -DQPSK channel, and the number of slots per TDMA frame allocated by element "timeslot assigned" should match the basic service information.

When the BS assigns a channel for packet data, it should allocate a channel within the MS's declared capabilities, with a modulation mode and number of slots per TDMA frame and RF bandwidth appropriate to the MS's PDP context(s) that are in active use.

NOTE 3: It is optional for a CA MS to be capable of using a multi-slot channel, or of supporting concurrent channels on one carrier, or of supporting concurrent multi-carrier operation, or of supporting D8PSK channels, or of supporting QAM channels, or of supporting bandwidths greater than 25 kHz. It is optional for a DA MS to be capable of supporting concurrent channels on one carrier, or of supporting concurrent multi-carrier operation, or of supporting more than one QAM bandwidth, or of supporting  $\pi/4$ -DQPSK channels, or of supporting D8PSK channels. The BS should use the information on MS capabilities provided in the "class of MS" and "extended capabilities" elements (see clause 16) when allocating resources; also, when the BS assigns a  $\pi/4$ -DQPSK or D8PSK channel for packet data, it should use the capability information provided in the "resource request" element (if the MS included the "resource request" element in the SMDCP signalling; see clause 28).

NOTE 4: In many cases, the MS may choose whether to move to an allocated channel (see clause 23.5.4.2). This applies for both individually addressed and group addressed channel allocations. BS designers should take account of this in their BS algorithms.

## 23.5.4.2 Reception of channel allocation

### 23.5.4.2.1 Channel allocation types

The "channel allocation" element includes a two-bit element "allocation type", which is intended to aid interpretation of the allocation. The precise procedures are defined in clauses 23.5.4.2.2, 23.5.4.2.3 and 23.5.4.2.4.

The values for the "allocation type" are as follows:

- a) 00<sub>2</sub>: Replace current channel with specified channel.

This indicates that the allocated channel is intended to replace the current channel (i.e. the channel on which the command was received). This replacement applies only to the channel on which the command was received, not to any other concurrent channels that the MS may be using on that carrier. If the current channel is a multi-slot channel, the replacement applies to all the timeslots comprising that channel.

The "Replace" mechanism may be used to move the MS to a different resource allocation. Otherwise it may be used if the BS wishes to increase or decrease the number of slots allocated to a particular assigned channel; the BS sends a "Replace" channel allocation on the assigned channel indicating the revised slot allocation.

- b) 01<sub>2</sub>: Additional channel allocation.

This indicates the allocation of an additional independent channel for an independent service e.g. a concurrent service. It cannot be used for changing the configuration of the current channel (see above).

- c) 10<sub>2</sub>: Quit current channel and go to specified channel.

This allows the BS to replace the current channel but without maintaining full service. This means that the physical layer service is no longer available for the higher layers to use, though the higher layer service is not necessarily disconnected. Any current traffic transmit/receive authorization does not apply on the new channel (see clause 23.8.2).

- d) 11<sub>2</sub>: Replace current channel with specified channel, plus MCCH/SCCH or additional  $\pi/4$ -DQPSK carrier specific signalling channel (CSS channel) in timeslot 1.

This indicates that the specified channel is intended to replace the current channel (i.e. the channel on which the command was received). If the specified carrier is the CA main carrier, it indicates that a CA MS may, if capable, use also the MCCH or the appropriate common SCCH for that MS. If the specified carrier is not the MS's main carrier, it indicates that the MS (either CA MS or DA MS) may, if capable, use timeslot 1 as an additional channel - referred to as a CSS channel - to increase signalling capacity between the MS and BS. If the MS is not capable of receiving both the specified channel and the MCCH/SCCH or CSS channel then the specified channel shall take precedence.

If the specified carrier is the CA main carrier and a CA MS chooses to use the MCCH or the appropriate common SCCH then it shall regard that channel as a common control channel (in the usual way), within the capabilities of that MS.

If the specified carrier is not the MS's main carrier and the MS (either CA MS or DA MS) chooses to use the CSS channel then it shall regard that CSS channel as an independent single-slot  $\pi/4$ -DQPSK channel. For the purposes of the general procedures for transmission and reception of signalling messages, the MS shall apply those procedures as if the CSS channel were a  $\pi/4$ -DQPSK assigned channel, allocated by a specific MAC-RESOURCE or MAC-END PDU with "timeslot assigned" = 1000<sub>2</sub>, i.e. allocation of timeslot 1.

However, the MS is only required to receive the CSS channel within the capabilities of that MS. Also, reduced channel maintenance procedures shall apply on the CSS channel, and the CSS channel becomes invalid when the MS has no other assigned channel on that carrier (see clause 23.5.6.2).

**EXAMPLE:** The BS might decide to allocate a CSS channel to provide information to MSs on that carrier about new calls, e.g. late entry signalling, without disturbing the operation of the assigned SCCHs and traffic channels on the other timeslots. The CSS channel could also be used for other signalling purposes such as status messages or packet data.

**NOTE 1:** The BS may allocate the CSS channel to all MSs using that carrier, by setting the "allocation type" to 11<sub>2</sub> in all the channel allocations. Slot 1 could also be an assigned channel for some MSs e.g. for advanced links with low data transfer throughput. The channel is then shared between the MSs.

An MS in a circuit mode call may, for example, send the U-TX DEMAND PDU on the CSS channel, e.g. with a high priority request. However, if FACCH is available on the assigned channel, then the MS should use this in preference to the CSS channel.

**NOTE 2:** The MS only receives the common channel (i.e. MCCH or common SCCH) or CSS channel within the capabilities of that MS. For example, a frequency half duplex MS in a simplex circuit mode call is permitted to receive the common or CSS channel while it is receiving traffic on the assigned channel even if it is not capable of receiving the common or CSS channel while it is transmitting traffic.

**NOTE 3:** In the present document, use of "allocation type" 11<sub>2</sub> is not appropriate when the BS is allocating a QAM channel.

Use of "allocation type" 11<sub>2</sub> is valid when the BS is allocating a  $\pi/4$ -DQPSK or D8PSK channel; in both cases, the CSS channel is a  $\pi/4$ -DQPSK channel.

NOTE 4: In the present document, if an MS receives "allocation type" 11<sub>2</sub> when the BS is allocating a QAM channel, the MS should regard the allocation as "allocation type" 00<sub>2</sub> (replace current channel with specified channel).

NOTE 5: "Allocation type" 11<sub>2</sub> is valid for both CA MSs and DA MSs when the BS is allocating a  $\pi/4$ -DQPSK or D8PSK channel.

- For a CA MS, "allocation type" 11<sub>2</sub> indicates that the CA MS may use also the MCCH (or the appropriate common SCCH for that MS) or the CSS channel in timeslot 1 - depending on whether the specified carrier is the CA MS's main carrier (as described above).
- A DA MS may receive "allocation type" 11<sub>2</sub> when the BS is allocating a  $\pi/4$ -DQPSK or D8PSK channel. The specified carrier is a phase modulation carrier, which is therefore not the DA MS's main carrier. Therefore, as described above, the DA MS may then, if capable, use timeslot 1 as a CSS channel, applying the general procedures for transmission and reception of signalling messages (within the capabilities of the MS) as if the CSS channel were an independent single-slot  $\pi/4$ -DQPSK assigned channel. This applies even if that carrier is being used as the main carrier for a CA cell.

As usual for a CSS channel, reduced channel maintenance procedures apply on the CSS channel (see clause 23.5.6.2). For example, the MS does not check validity of the AACH for channel maintenance purposes. Therefore the MS does not leave the CSS channel as a result of receiving AACH indicating common control usage. However the CSS channel becomes invalid for the MS when the MS has no other assigned channel on that carrier (see clause 23.5.6.2).

MSs on a CSS channel check the common/assigned designation of uplink slots when performing random access (see clause 23.5.1.4.15). Therefore, if DA MS(s) are using slot 1 of a CA main carrier as a CSS channel, the BS should designate some random access opportunities as "common and assigned" or "assigned only".

In many cases, the MS may choose whether to obey a channel allocation e.g. if the channel allocation is received on its common control channel, or for an additional channel allocation. The MS-MAC refers to the higher layers for a decision. For a group addressed channel allocation, the higher layers may either make an immediate decision on whether to accept the channel allocation or may delay the decision. However, for an individually addressed channel allocation, the MS needs to make an immediate decision on whether to accept a particular channel allocation.

NOTE 6: For a group call, especially on a (quasi-)transmission trunked system, the MS may sometimes receive a channel allocation on the group address and sometimes on its individual address.

When the higher layers respond with their decision on whether to accept a channel allocation, they may indicate "accept" or "reject" or, in some cases, they may indicate "ignore". The MAC actions for "reject" and "ignore" are the same except when a "replace" or "replace + CSS channel" or "quit" channel allocation is received on an assigned channel or when a "quit" channel allocation is received on a CSS channel (see clauses 23.5.4.2.3 and 23.5.4.2.4).

The "reject" instruction is used when the higher layers may choose not to accept the channel allocation. The "ignore" instruction applies only in specific protocol cases when the higher layers are required by the protocol to ignore specific PDUs and to instruct the MAC to ignore any channel allocation received with those PDUs e.g. when the MS is transmitting traffic and the CMCE receives a group addressed D-TX GRANTED or D-TX INTERRUPT PDU, or in some instances of receipt of a group addressed D-SETUP PDU when the MS is trying to make a call to that group (see clause 14.5.2), or if the SNDCP receives a group addressed SN-END OF DATA PDU while the READY timer is active (see clause 28.2.4.7).

The following procedures for reception of a channel allocation indicate the physical layer service provided by the channel to the higher layers.

The MS-MAC generally uses the TMC-CONFIGURE indication primitive to inform the higher layers when it has lost physical resources. There are also some error conditions (as defined in clause 23.5.4.2.3 procedure a1, or if the MS leaves the channel as a result of channel maintenance procedures) for which the MS-MAC may either issue a TMC-CONFIGURE indication primitive indicating loss of the physical resource or alternatively may issue the TMA-RELEASE indication primitive to indicate loss of the connection.

NOTE 7: When the LLC receives a TMC-CONFIGURE indication primitive indicating loss of the physical resource, it may retain any advanced links on that resource for potential continuation (see clause 22.3.5). When the LLC receives the TMA-RELEASE indication primitive, it locally disconnects any advanced links on that resource (see clause 22.3.3.4).

#### 23.5.4.2.2 Reception of channel allocation on MS's common control channel

A CA MS's common control channel is the MCCH or a  $\pi/4$ -DQPSK common SCCH. A DA MS's common control channel is the MCCH-Q or a QAM common SCCH. This clause applies to MSs that are in common mode on their common control channel. In some cases other MSs may be in assigned mode on that channel, in which case those other MSs obey the procedures in clause 23.5.4.2.3 (or clause 23.5.4.2.4).

If the MS receives a channel allocation on its common control channel for one of its valid addresses or for a corresponding event label, then the "allocation type" may be  $00_2$  (Replace current channel) or  $01_2$  (Additional channel) or  $11_2$  (Replace current channel, and add CSS channel).

If a TM-SDU was included within the PDU that allocated the channel then the MS-MAC shall set the "channel change response required" parameter to "true" in the TMA-UNITDATA indication primitive, to indicate that a response is required to instruct the MS-MAC whether it should obey the allocation; the MS-MAC may also include information about the channel allocation, using the "channel information" parameter. The MS-MAC shall generate a local identifier for the channel allocation, referred to as the "channel change handle", and shall include it in the TMA-UNITDATA indication primitive, enabling unique identification of the related response from the higher layers. If a TM-SDU was not included within the PDU that allocated the channel then the MS-MAC shall issue a TMA-UNITDATA indication primitive containing the "channel change response required" parameter set to "true" (and a channel change handle and, optionally, the channel information parameter) and with no TM-SDU.

NOTE 1: It is optional for the MS to obey a channel allocation received on its common control channel. According to the protocol model, the MS-MAC refers to the higher layers so that, for example, for a circuit mode group call, the MS-MAC does not move to the channel if the CMCE does not accept the associated message. However, in an implementation, the MS is permitted to obey all individually addressed channel allocations in which case the primitive exchange is unnecessary in practice.

When the BS sends a channel allocation on a common control channel, it is recommended that the BS includes a higher layer message indicating the intended usage of the channel allocation. Even if only an LLC acknowledgement is included with the channel allocation, this may enable the MS to deduce the intended usage (e.g. in the case of medium channel assignment to a called MS).

If "allocation type" =  $01_2$  and the MS is capable of operating with concurrent channels and the MS is not already receiving the indicated channel then the MS-MAC shall allocate an endpoint identifier for the new channel. The MS-MAC shall include both the endpoint identifier of the current channel (i.e. the channel on which the channel allocation PDU was received) and the endpoint identifier of the newly allocated channel (parameter "new endpoint identifier") in the TMA-UNITDATA indication primitive.

NOTE 2: A new endpoint identifier will usually be required. However, for example, in the case of independent allocation of uplink and downlink for concurrent calls involving the same MS, that MS may receive independent channel allocations with the same carrier number and same element "timeslot assigned" but with a different up/downlink assigned designation.

NOTE 3: The new endpoint identifier enables the higher layers to make the intended usage of the new channel if the MS-MAC obeys the channel allocation. For example, for an AL-SETUP PDU for a new advanced link, sent with the additional channel allocation, the new advanced link is intended to be on the allocated channel.

If "allocation type" =  $11_2$  and the MS is capable of using the common or CSS channel then the MS-MAC shall allocate an endpoint identifier for the common or CSS channel. The MS-MAC shall include both the endpoint identifier of the current channel and the endpoint identifier of the common or CSS channel (parameter "CSS endpoint identifier") in the TMA-UNITDATA indication primitive.

NOTE 4: The CSS endpoint identifier enables the higher layers to make correct usage of the common or CSS channel if the MS-MAC obeys the channel allocation.

The MS-MAC should then receive a response (TMC-CONFIGURE request primitive) from the higher layers indicating whether it should obey the allocation. For an individually addressed channel allocation, the MS-MAC should expect that the response from the higher layers will be immediate. However, for a group addressed channel allocation, the response from the higher layers may be immediate or may be delayed, in which case the MS-MAC continues to obey the normal MAC procedures on the common control channel in the interim time.

NOTE 5: For the purposes of the protocol description, it is assumed that, in the case of an immediate decision by the higher layers, the process of the MAC issuing the TMA-UNITDATA indication primitive and then receiving the corresponding TMC-CONFIGURE request primitive is effectively instantaneous.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" or "ignore" then the MS-MAC shall ignore the channel allocation corresponding to the channel change handle. The MS may use any subslot or slot(s) that are granted on the current channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation command corresponding to the channel change handle, using the appropriate procedure a) or b):

- a) If "allocation type" = 00<sub>2</sub> (Replace) or 11<sub>2</sub> (Replace + CSS channel) in the "channel allocation" element then the MS shall move from the current channel (i.e. the channel on which the channel allocation PDU was received) to the specified channel. It shall assume that the allocated channel will provide the same service to the LLC as the current channel, corresponding to the same endpoint identifier (see note 6).

If the MS was receiving other channels on the main carrier, and it is not capable of receiving those other channels as well as the newly allocated channel, then the MS-MAC shall issue a TMC-CONFIGURE indication primitive to the higher layers for any channels that it can no longer receive in order to indicate that the physical resource on those channels is lost. Otherwise, if the MS is capable of continuing to receive its other channels, then those other channels are not affected.

If "allocation type" = 00<sub>2</sub> then the MS shall not continue to use the common control channel.

If "allocation type" = 11<sub>2</sub> and the assigned carrier is the CA main carrier then a CA MS may, if capable, use also the MCCH or the appropriate common SCCH for that MS. If the assigned carrier is not the MS's main carrier then the MS (either CA MS or DA MS) may, if capable, use slot 1 of the assigned carrier as a CSS channel. If the MS is not capable of receiving both the assigned channel and the common or CSS channel then the MS shall ignore the common/CSS part of the allocation.

NOTE 6: For a "replace" or "replace + CSS channel" command within the cell, the service provided to the LLC is maintained both for the basic link and for any advanced link(s) on the current channel. This applies even if the number of allocated timeslots or modulation mode or bandwidth changes. (Though, for  $\pi/4$ -DQPSK operation, in the case of a change of the number of allocated timeslots, the MS is not precluded from performing an LLC reset if the AL-SETUP PDU contained radio resource information; also, in the case of a change of modulation mode or bandwidth, the MS is not precluded from performing an LLC reset in order to avoid use of fragmentation for re-transmissions of segments cut for transmission on the old channel.) In the case of a cell reselection, the MLE decides whether to release current advanced links or attempt reconnection. If the MLE does not attempt reconnection then any current advanced links are released when the MS obeys a channel allocation indicating a cell change.

NOTE 7: A "replace" or "replace + CSS channel" command applies only to the channel on which the message was received, and so cannot be used to simultaneously replace other concurrent channels on that carrier when allocating a channel on another carrier. However, if the channel allocation PDU includes a slot grant on the current channel with "granting delay" > 0000<sub>2</sub> then the MS does not change channel immediately (see clause 23.5.4.3.1). During the interim time, the MS should continue to receive its other concurrent channels, since the BS may also send a "replace" or "replace + CSS channel" command on one of those channels, enabling both services to be maintained on the new carrier. Then, in the timing procedure for the carrier change, the MS may use the later (or latest) of the specified times.

- b) If "allocation type" = 01<sub>2</sub> (Add) in the "channel allocation" element then the MS shall obey the command to receive the allocated channel.

If the MS is not capable of receiving all concurrent channels as well as the newly allocated channel, then the MS-MAC shall issue a TMC-CONFIGURE indication primitive to the higher layers for those channels that it can no longer receive in order to indicate that the physical resource on those channels is lost. Otherwise the MS shall continue to receive all concurrent channels, including the channel on which the channel allocation PDU was received, as well as the newly allocated channel.

After a channel change, the MS-MAC shall inform the higher layers about the channel now in use using the TMC-SELECT indication primitive.

NOTE 8: For DA, the BS may allocate the MCCH-Q physical channel(s) as a QAM assigned channel for some MSs that are camped on the cell. Then the MSs in common mode and the MSs in assigned mode share the channel. Similarly, the BS may allocate a physical channel used as a QAM common SCCH also as a QAM assigned channel for some MSs, with the channel shared between the MSs in common mode and the MSs in assigned mode. As indicated above, it is optional for an MS to obey a channel allocation received on the common control channel; this applies for both individually addressed and group addressed channel allocations. However, MSs in assigned mode may use some slightly different procedures from MSs in common mode. (For example, napping may apply when the MS is in assigned mode, whereas energy economy or part-time reception mode may apply when the MS is in common mode; and the MS may use a different value of the event label inactivity time-out.) BS designers should take account of this in their BS algorithms.

#### 23.5.4.2.3 Reception of channel allocation on assigned channel

This clause applies to MSs that are in assigned mode, having accepted a channel allocation for an assigned channel. In some cases other MSs may be in common mode on that channel, in which case those other MSs obey the procedures in clause 23.5.4.2.2.

If the MS receives a channel allocation on an assigned channel for one of its valid addresses or for a corresponding event label, then the "allocation type" may take any of the following four values:

- 00<sub>2</sub> (Replace current channel), in which case the MS shall assume that the allocated channel will provide the current service.
- 01<sub>2</sub> (Additional channel), in which case the MS shall assume that the channel is intended for the purpose indicated in the higher layer message.
- 10<sub>2</sub> (Quit current channel), in which case the MS should assume that the current service on that channel is not fully maintained. This means that the physical layer service is no longer available for the higher layers to use, though the higher layer service is not necessarily disconnected. Any current traffic transmit/receive authorization does not apply on the new channel.
- 11<sub>2</sub> (Replace current channel, and add CSS channel), in which case the MS shall assume that the allocated channel will provide the current service, and that timeslot 1 (or the MCCH or common SCCH) may be used for additional signalling.

NOTE 1: For a "replace" or "replace + CSS channel" command received while the MS is in a circuit mode call, current traffic transmit and/or receive authorization may apply on the allocated channel; refer to clause 23.8.2.

The MS-MAC shall follow the appropriate procedure a), b) or c):

- a) For allocation type 00<sub>2</sub> (Replace) or 11<sub>2</sub> (Replace + CSS channel), the appropriate procedure shall apply as follows:
- 1) If a TM-SDU was not included within the PDU that allocated the channel, and:
    - the MS does not have a concurrent assigned channel; or
    - the MS would still be able to receive any concurrent assigned channels after moving to the allocated channel,

then the MS-MAC shall decide whether to obey the channel allocation as follows:

- If the MS is capable of using the allocated channel then the MS-MAC shall obey the channel allocation. The MS shall cease to receive the current channel (unless it has a concurrent independent allocation on that channel, see note 7) and shall move to the allocated channel.
- Otherwise, if the MS is not capable of using the allocated channel (e.g. the replacement channel has a larger number of slots than the current channel and the MS cannot support the channel, or the MS cannot support the indicated modulation mode or bandwidth) then the MS-MAC shall reject the channel allocation. The MS-MAC shall cease to receive the current channel and shall issue either a TMA-RELEASE indication primitive to indicate loss of the connection or a TMC-CONFIGURE indication primitive indicating loss of the physical resource (unless it has a concurrent independent allocation on that channel, see note 7). The MS may use any subslot or slot(s) that are granted on the current channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel. If the MS does not have a concurrent assigned channel, it shall return to its common control channel.

NOTE 2: For allocation type 11<sub>2</sub>: when the above procedure refers to the MS not being capable of using the allocated channel, this refers only to the allocated channel as indicated by element "timeslot assigned", not to the CSS channel.

- 2) If a TM-SDU was included within the PDU that allocated the channel, or the MS has a concurrent assigned channel that it would be unable to receive as a result of moving to the allocated channel, then the MS-MAC shall set the "channel change response required" parameter in the TMA-UNITDATA indication primitive to "true" (and shall include a channel change handle and may include the channel information parameter). The MS-MAC shall then wait for a response from the higher layers:
  - If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation corresponding to the channel change handle. The MS shall cease to receive the current channel (unless it has a concurrent independent allocation on that channel, see note 7) and shall move to the allocated channel.
  - If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" then the MS shall cease to receive the current channel (unless it has a concurrent independent allocation on that channel, see note 7). The MS may use any subslot or slot(s) that are granted on the current channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel. If the MS does not have a concurrent assigned channel, it shall return to its common control channel.
  - If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "ignore" then the MS-MAC shall ignore the channel allocation corresponding to the channel change handle and continue to use the current channel. The MS may use any subslot or slot(s) that are granted on the current channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.
  - If the higher layers do not return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter within a time T.216 following receipt of the channel allocation then the MS shall cease to receive the current channel (unless it has a concurrent independent allocation on that channel, see note 7). If the MS does not have a concurrent assigned channel, it shall return to its common control channel. If the higher layers later return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS should move to the allocated channel.

NOTE 3: Thus, when the higher layers wish the MS-MAC to ignore a replacement channel allocation on an assigned channel, they return the "channel change accepted" parameter set to "ignore" within a time T.216 in order for the MS-MAC to act on it.

NOTE 4: In the case of a channel allocation with a slot grant on the current channel, when the above procedures 1) and 2) refer to the MS ceasing to receive the current channel, the MS should not leave the channel until after the end of the last uplink slot granted by that PDU (or the end of the slot containing a granted subslot). Similarly, if the current channel is a multi-slot channel, and the next immediate uplink slot following the channel allocation is part of the current channel, and the MS is transmitting traffic in that slot or was previously granted that slot (or a subslot in that slot) for reserved access, the MS should not leave until after the end of that next immediate uplink slot.

NOTE 5: A "replace" or "replace + CSS channel" command applies only to the channel on which the message was received, and so cannot be used to simultaneously replace other concurrent channels on that carrier when allocating a channel on another carrier. However, if the channel allocation PDU includes a slot grant on the current channel with "granting delay" > 0000<sub>2</sub> then the MS does not change channel immediately (see clause 23.5.4.3.1). During the interim time, the MS should continue to receive its other concurrent channels, since the BS may also send a "replace" or "replace + CSS channel" command on one of those channels, enabling both services to be maintained on the new carrier. Then, in the timing procedure for the carrier change, the MS may use the later (or latest) of the specified times.

- b) For allocation type 01<sub>2</sub> (Add), the MS-MAC shall set the "channel change response required" parameter in the TMA-UNITDATA indication primitive to "true" to indicate that a response is required to instruct the MAC whether it should accept the allocation (and shall include a channel change handle and may include the channel information parameter). If the decision is delayed for a group addressed channel allocation then the MS-MAC may continue to use the current channel in the interim time.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation command corresponding to the channel change handle. It may also continue to use the current channel if it is capable of doing so.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" or "ignore" then the MS-MAC shall ignore the channel allocation corresponding to the channel change handle and continue to use the current channel. The MS may use any subslot or slot(s) that are granted on the current channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.

- c) For allocation type 10<sub>2</sub> (Quit), the MS-MAC shall obey the procedure defined in procedure a) above for allocation type 00<sub>2</sub> (Replace) except that, if the MS ceases to receive the current channel, the MS-MAC shall issue a TMC-CONFIGURE indication primitive for the current channel in order to indicate that the physical resource has been lost.

If the MS is already receiving the allocated channel then any services on that channel are not affected and the endpoint identifier is unchanged.

After obeying a channel allocation command then, if the MS is not capable of receiving all concurrent channels as well as the newly allocated channel, the MS-MAC shall issue a TMC-CONFIGURE indication primitive to the higher layers for those channels that it can no longer receive in order to indicate that the physical resource on those channels is lost.

After a channel change, the MS-MAC shall inform the higher layers about the channel now in use using the TMC-SELECT indication primitive.

NOTE 6: For allocation type 01<sub>2</sub> (Add) or 11<sub>2</sub> (Replace + CSS channel), the MS-MAC may need to allocate additional endpoint identifiers, in a similar manner to that described in clause 23.5.4.2.2.

NOTE 7: As indicated in clause 23.3.4, it is possible that an MS may receive concurrent independent channel allocations for the uplink and downlink of the same channel. If the BS has sent channel allocations that have assigned the uplink and downlink independently to the same MS (e.g. both on the MS's individual address, or one on the MS's individual address and the other on one of the MS's valid group addresses) then the BS should include a higher layer message when it sends a "replace" or "replace + CSS channel" command on that channel, thus enabling the MS to deduce which channel allocation is being replaced. This applies also for a "quit" command.

NOTE 8: When the BS sends an additional channel allocation (allocation type 01<sub>2</sub>) on an assigned channel, it should include a higher layer message indicating the intended usage of the channel allocation; even if only an LLC acknowledgement is included with the channel allocation, this may enable the MS to deduce the intended usage.

#### 23.5.4.2.4 Reception of channel allocation on CSS channel

This clause applies to MSs that are using a CSS channel, having accepted the CSS part of a channel allocation with allocation type 11<sub>2</sub> (Replace + CSS channel) where the allocated carrier is not the MS's main carrier.

If the MS receives a channel allocation on a CSS channel for one of its valid addresses or for a corresponding event label, then the "allocation type" may take any of the four values:

- a) For allocation type 00<sub>2</sub> (Replace) or 11<sub>2</sub> (Replace + CSS channel), the MS-MAC shall set the "channel change response required" parameter in the TMA-UNITDATA indication primitive to "true" (and shall include a channel change handle and may include the channel information parameter). If the decision is delayed for a group addressed channel allocation then the MS-MAC may continue to use the CSS channel in the interim time.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" or "ignore" then the MS-MAC shall ignore the channel allocation and may continue to use the CSS channel. The MS may use any subslot or slot(s) that are granted on the CSS channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation command. If "allocation type" = 11<sub>2</sub> in a channel allocation indicating the current carrier then the MS may continue to use the CSS channel. However, if either:

- 1) "allocation type" = 00<sub>2</sub>; or
- 2) "allocation type" = 11<sub>2</sub> in a channel allocation directing the MS to another carrier;

then the MS shall not continue to use the CSS channel on the current carrier though, in case 2), it may use the common or CSS channel on the new carrier.

- b) For allocation type 01<sub>2</sub> (Add), the MS-MAC shall set the "channel change response required" parameter in the TMA-UNITDATA indication primitive to "true" (and shall include a channel change handle and may include the channel information parameter). If the decision is delayed for a group addressed channel allocation then the MS-MAC may continue to use the CSS channel in the interim time.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" or "ignore" then the MS-MAC shall ignore the channel allocation and may continue to use the CSS channel. The MS may use any subslot or slot(s) that are granted on the CSS channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.

If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation command. It may also continue to use the CSS channel if it is capable of doing so.

- c) For allocation type 10<sub>2</sub> (Quit), the appropriate procedure shall apply as follows:
  - 1) If a TM-SDU was not included within the PDU that allocated the channel and the MS would still be able to receive its current assigned channel(s) after moving to the allocated channel and the MS is capable of using the allocated channel then the MS-MAC shall obey the channel allocation. It shall cease to receive the CSS channel using the timing for an immediate decision and shall move to the allocated channel.
  - 2) If a TM-SDU was not included within the PDU that allocated the channel, and either the MS would be unable to receive its current assigned channel(s) after moving to the allocated channel (e.g. if the channel allocation is directing the MS to the common control channel and the MS is not capable of concurrent multi-carrier operation) or the MS is not capable of using the allocated channel, then the MS-MAC shall cease to receive the CSS channel using the timing for an immediate decision but shall not move to the allocated channel.

- 3) If a TM-SDU was included within the PDU that allocated the channel then the MS-MAC shall set the "channel change response required" parameter in the TMA-UNITDATA indication primitive to "true" (and shall include a channel change handle and may include the channel information parameter). The MS-MAC shall then wait for a response from the higher layers:
- If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS-MAC shall obey the channel allocation. The MS shall cease to receive the CSS channel and shall move to the allocated channel.
  - If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "reject" then the MS shall cease to receive the CSS channel. The MS may use any subslot or slot(s) that are granted on the CSS channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.
  - If the higher layers return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "ignore" then the MS-MAC shall ignore the channel allocation and may continue to use the CSS channel. The MS may use any subslot or slot(s) that are granted on the CSS channel but shall ignore a slot grant if element "position of grant" in the channel allocation PDU indicated the allocated channel.
  - If the higher layers do not return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter within a time T.216 following receipt of the channel allocation then the MS shall cease to receive the CSS channel. If the higher layers later return a TMC-CONFIGURE request primitive containing the "channel change accepted" parameter set to "accept" then the MS should start to receive the allocated channel.

If the MS ceases to receive the CSS channel, the MS-MAC shall issue a TMC-CONFIGURE indication primitive for the CSS channel in order to indicate that the physical resource has been lost.

If the MS is already receiving the allocated channel then any services on that channel are not affected and the endpoint identifier is unchanged.

NOTE 1: In the case of a channel allocation with a slot grant on the CSS channel, when the above procedures refer to the MS ceasing to receive the CSS channel, the MS should not leave the channel until after the end of the last uplink slot granted by that PDU (or the end of the slot containing a granted subslot).

After obeying a channel allocation command then, if the MS is not capable of receiving all concurrent channels as well as the newly allocated channel, the MS-MAC shall issue a TMC-CONFIGURE indication primitive to the higher layers for those channels that it can no longer receive in order to indicate that the physical resource on those channels is lost.

After a channel change, the MS-MAC shall inform the higher layers about the channel now in use using the TMC-SELECT indication primitive.

NOTE 2: For allocation type 01<sub>2</sub> (Add) or 11<sub>2</sub> (Replace + CSS channel), the MS-MAC may need to allocate additional endpoint identifiers, in a similar manner to that described in clause 23.5.4.2.2.

NOTE 3: When the BS sends a channel allocation on a CSS channel, it should include a higher layer message indicating the intended usage of the channel allocation except in some cases of allocation type 10<sub>2</sub> (Quit). Even if only an LLC acknowledgement is included with the channel allocation, this may enable the MS to deduce the intended usage.

### 23.5.4.3 Channel change

#### 23.5.4.3.1 Timing of channel change

When the MS-MAC obeys a channel allocation command, it shall inform the lower layers of any change of RF carrier and/or timeslot(s) and/or bandwidth and/or modulation mode - using the TMV-CONFIGURE request primitive. The carrier information is contained in the "channel allocation" element (see clause 21).

For a change of carrier within the cell, the MS shall assume that the current frame and slot synchronization apply also on the new carrier.

NOTE 1: When the MS obeys a channel allocation command for an eccentric channel, the MS may perceive a larger timing difference on the new channel relative to the old channel than when moving to a non-eccentric channel; see clauses 7.7 and 7.8. The same applies when the MS moves from an eccentric channel to another channel (for example, when the MS returns to its common control channel).

When directed to a CA new cell, the MS-MAC shall assume the frame and slot synchronization from the SYNC and SYSINFO PDUs most recently received while scanning the main carrier of that cell (see clause 23.7); when directed to a DA new cell, the MS-MAC shall assume the frame and slot synchronization from the SYNC-DA and SYSINFO-DA PDUs most recently received while scanning the main carrier of that cell and when reading the SYSINFO-DA PDU on that cell (see clause 23.7). On receiving the TL-SELECT indication primitive for a cell change channel allocation, the MLE returns a TL-SELECT response primitive indicating the main carrier of the new cell; the LLC passes the response primitive to the MAC as a TMC-SELECT response primitive, enabling the MAC to reference the correct information.

NOTE 2: When the MS obeys a channel allocation command for an eccentric channel on a new cell, the MS may perceive a larger timing difference on the eccentric channel relative to the main carrier of the new cell than when moving to a non-eccentric channel on the new cell; see clause 7.7.

If a "basic slot granting" or "multiple slot granting" element is included in the same PDU as the "channel allocation" element then:

- if element "position of grant" in the PDU indicates "Current Channel", the MS shall obey the procedure for use of reserved slots (see clause 23.5.2) on the current channel;
- otherwise the MS shall assume that the slot grant is on the allocated channel.

NOTE 3: If the MS does not obey the channel allocation, it may use any subslot or slot(s) that are granted on the current channel but ignores a slot grant if element "position of grant" in the PDU indicates the allocated channel.

The timing of the move to an allocated channel shall be as follows:

- 1) If the MS obeys an individually addressed channel allocation, or if it makes an immediate decision to obey a group addressed channel allocation, then the first uplink (respectively downlink) slot on the allocated channel shall be defined relative to either:
  - a) the end of the downlink slot containing the channel allocation; or
  - b) in the case of a channel allocation with a slot grant on the current channel (with "granting delay"  $\neq 1111_2$ ):
    - the end of the last uplink slot granted by that PDU (or the end of the slot containing a granted subslot or, for a multiple slot grant, the end of the last slot containing a granted subslot); or
  - c) if the current channel is a multi-slot channel, and the next immediate uplink slot following the channel allocation is part of the current channel, and the MS is transmitting traffic in that slot or was previously granted that slot (or a subslot in that slot) for reserved access:
    - the end of that next immediate uplink slot;

whichever is the later; see note 4. Then, after one timeslot duration, the first uplink (respectively downlink) slot on the allocated channel shall be defined as the next uplink (respectively downlink) slot that corresponds to one of the timeslots indicated by element "timeslot assigned". This timing rule shall apply both for allocation within the same cell and for a different cell.

NOTE 4: For the purposes of this procedure, the time of the end of the slot is defined as being just less than one timeslot duration after the start of that slot (i.e. the time of the end of the slot is regarded as occurring an instant before the start of the next slot), where the start of the slot is as specified in clauses 7, 9.4.3.4 and 9.4.7.4. This applies even though, in case a), the MS may need to receive the downlink beyond the "end of the downlink slot" in order to decode that downlink slot. Also, after switching, the MS may need to start receiving the downlink before the start of the first slot on the allocated channel in order to decode that slot.

For a slot grant on the allocated channel, granting delay = 0000<sub>2</sub> in the "basic slot granting" element (or in the first "basic slot granting" element in a "multiple slot granting" element) shall refer to the use of the first uplink slot on the allocated channel. Granting delay > 0000<sub>2</sub> shall then refer to delaying by the specified number of delay opportunities on the allocated channel as defined by element "timeslot assigned".

NOTE 5: Condition b) may apply for a channel allocation with either a basic slot grant or a multiple slot grant on the current channel. In either case, condition b) refers to the end of the last uplink slot in which either the whole slot or a subslot is granted by that PDU.

NOTE 6: Condition c) above applies only to a frequency full duplex or fast switching MS. It assumes that the MS cannot stop transmission immediately and should not stop in the middle of a full slot. For example, if the MS is transmitting traffic and receives a channel allocation sent in downlink slot 1, the MS should continue to transmit in the immediately following uplink slot 4 (if that is a valid traffic slot), before moving to the allocated channel.

NOTE 7: The following are examples of the channel timing, for allocation within the same cell.

- i) For a channel allocation sent in slot 1, assigning timeslot 1, e.g. on another RF carrier:
  - the first uplink slot on the allocated channel is the uplink slot 1 of the same TDMA frame;
  - the first downlink slot on the allocated channel is the downlink slot 1 of the next TDMA frame.
- ii) For a channel allocation sent in slot 1, assigning timeslot 2:
  - the first uplink slot on the allocated channel is the uplink slot 2 of the same TDMA frame;
  - the first downlink slot on the allocated channel is the downlink slot 2 of the next TDMA frame.
- iii) For a channel allocation sent in slot 1, assigning timeslot 4:
  - the first downlink (respectively uplink) slot on the allocated channel is the downlink (respectively uplink) slot 4 of the same TDMA frame (i.e. frame number X where the channel allocation was sent in slot 1 of frame X).
- iv) For a channel allocation sent in slot 1, with a single subslot grant on the current channel in that TDMA frame, and assigning timeslot 1:
  - the first downlink (respectively uplink) slot on the allocated channel is the downlink (respectively uplink) slot 1 of the next TDMA frame.
- v) For a channel allocation sent in slot 1, with a single subslot grant on the current channel in that TDMA frame, and assigning timeslot 2:
  - the first downlink (respectively uplink) slot on the allocated channel is the downlink (respectively uplink) slot 2 of the next TDMA frame.
- vi) For a channel allocation sent in slot 1, with a single subslot grant on the current channel in that TDMA frame, and assigning timeslot 3:
  - the first uplink slot on the allocated channel is the uplink slot 3 of the same TDMA frame;
  - the first downlink slot on the allocated channel is the downlink slot 3 of the next TDMA frame.
- vii) For a channel allocation sent in slot 1, with a single subslot grant on the current channel in that TDMA frame, and assigning timeslots 1 and 4:
  - the first uplink slot on the allocated channel is the uplink slot 4 of the same TDMA frame;
  - the first downlink slot on the allocated channel is the downlink slot 1 of the next TDMA frame.

- viii) If a frequency full duplex or fast switching MS is transmitting traffic on a multi-slot channel comprising timeslots 1, 2 and 3, and receives a channel allocation sent in slot 2 of a frame in the range 1 to 17, replacing the current channel with timeslots 2, 3 and 4, then the MS continues to transmit traffic in uplink slot 1 before it switches channel. Then:
  - the first uplink slot on the allocated channel is the uplink slot 3 of the same TDMA frame;
  - the first downlink slot on the allocated channel is the downlink slot 2 of the next TDMA frame.
- ix) If the MS is on a two-slot channel comprising timeslots 2 and 3, and receives a channel allocation sent in slot 2 of frame X, with a multiple slot grant for slot 2 of the current TDMA frame (frame X) and slot 3 of the next TDMA frame but one (frame X + 2), and assigning timeslots 2, 3 and 4:
  - the first downlink slot on the allocated channel is the downlink slot 3 of frame X + 3;
  - the first uplink slot on the allocated channel is the uplink slot 2 of frame X + 3.

For allocation on a different cell, the MS still allows one timeslot duration (approximately 14,167 ms). Then the first uplink (respectively downlink) slot on the allocated channel on the new cell is the next uplink (respectively downlink) slot that corresponds to one of the timeslots indicated by element "timeslot assigned" - using the new cell synchronization. This timing applies whether the new cell is synchronized to the current cell or not. The normal rules for slot grants and CLCH(-Q) permission then apply on the allocated channel.

NOTE 8: Element "position of grant" is included to allow flexibility of channel scheduling by the BS. For example, if there is already traffic on the uplink of the allocated channel, the BS may wish to grant a subslot on the current channel for a layer 2 acknowledgement from an MS that is to receive traffic, e.g. in case of independent allocation of uplink and downlink. In other cases, granting on the allocated channel may often be more appropriate.

When using the layer 2 acknowledged service, the BS should grant a subslot on the current channel for the layer 2 acknowledgement from the MS when sending a channel allocation that the MS may choose to "reject". This is because, if the BS granted a subslot on the allocated channel and the MS did not move to the allocated channel, then the MS could not use the granted subslot on the allocated channel for the layer 2 acknowledgement.

- 2) If the MS decides to obey a group addressed channel allocation after a delay then the first uplink (respectively downlink) slot on the allocated channel shall be defined either relative to the time when the MS-MAC receives the TMC-CONFIGURE request primitive accepting the channel allocation or relative to the end of the slot in which the MS-MAC received the TMC-CONFIGURE request primitive. Then, after one timeslot duration, the first uplink (respectively downlink) slot on the allocated channel shall be defined as the next uplink (respectively downlink) slot that corresponds to one of the timeslots indicated by element "timeslot assigned". This timing rule shall apply both for allocation within the same cell and for a different cell.

For a slot grant on the allocated channel, the granting delay is defined relative to the first uplink slot on the allocated channel for an immediate decision (as specified in procedure 1) above). Therefore, in the case of a delayed decision, the MS-MAC shall not use the granted capacity unless it is capable of calculating the intended time of the granted capacity based on an immediate decision and the higher layers accept the channel allocation before that time occurs. If the MS-MAC does not use the granted capacity then, since uplink messages with a group address in the MAC header are only ever sent by reserved access, the MS should discard the uplink message intended to be sent in the granted capacity.

EXAMPLE: In an implementation, the MS-MAC could issue a MAC-READY signal for the group address and receive the TMA-UNITDATA request primitive but then report failure to send the message.

NOTE 9: Uplink messages with the group address in the MAC header are used only for the low-level group presence indication.

Slot granting is valid only on the channel on which the grant was made, except in the case of slots granted in the same PDU as a channel allocation and with element "position of grant" indicating the allocated channel. Therefore, after an MS has obeyed a channel allocation command then, if it is no longer using the channel on which the channel allocation was received, any slot grants received on the old channel before the channel allocation shall cease to be valid.

As defined in clauses 23.4.2.1 and 23.4.3.1, fragmentation and reconstruction apply to a specific control channel. Therefore, after an MS has obeyed a channel allocation command then, if it is no longer using the channel on which the channel allocation was received, it shall discontinue any ongoing uplink fragmentation on the old channel (reporting to the LLC that the transmission has failed) and shall also discard any partially reconstructed downlink TM-SDU.

#### 23.5.4.3.2 Use of "timeslot assigned"

If the "timeslot assigned" element  $\neq 0000_2$ , the MS-MAC shall note that the channel is an assigned channel, assigned for SCCH or for a circuit mode call.

If the "timeslot assigned" element =  $0000_2$ , a CA MS shall go to the appropriate common control channel as indicated by the last received SYSINFO or SYSINFO-Q PDU.

If the "timeslot assigned" element =  $0000_2$ , a DA MS shall go to the appropriate common control channel as indicated by the last received SYSINFO-DA PDU. The channel allocation may be augmented or non-augmented.

- a) If the channel allocation containing the "timeslot assigned" element set to  $0000_2$  is augmented, and the modulation mode indicates QAM, a DA MS shall use the other information provided in the channel allocation.
- b) If the channel allocation containing the "timeslot assigned" element set to  $0000_2$  is not augmented, or is augmented but the modulation mode does not indicate QAM, a DA MS shall:
  - go to the main carrier indicated by the last received SYSINFO-DA or SYNC-DA PDU (ignoring the carrier information in the channel allocation);
  - assume the bandwidth indicated by the last received SYSINFO-DA or SYNC-DA PDU;
  - assume QAM modulation mode;
  - assume the values of the maximum uplink QAM modulation level and BS link imbalance indicated by the last received SYSINFO-DA PDU;
  - assume that the conforming channel status is conforming;
  - assume a BS transmit power relative to the main carrier of 0 dB;
  - assume that CLCH(-Q) permission is as indicated by the "CLCH(-Q) permission" flag in the channel allocation.

NOTE 1: If a slot grant is included in the same PDU as the channel allocation and element "position of grant" indicates that the slot grant is on the allocated channel, the same procedure for the slot grant applies in method b) as for all other cases of a channel allocation; so, in this case, the MS regards the slot grant as applying on the appropriate common control channel on the main carrier indicated by the last received SYSINFO-DA or SYNC-DA PDU. Thus the MS follows the usual procedure as defined in clause 23.5.4.3.1.

Similarly, if an event label assignment is associated with the channel allocation, the same procedure for the event label assignment applies in method b) as for all other cases of a channel allocation; so, in this case, the MS regards the event label assignment as applying on the appropriate common control channel on the main carrier indicated by the last received SYSINFO-DA or SYNC-DA PDU. Thus the MS follows the usual procedure as defined in clauses 23.4.1.2.3.1 and 23.4.1.2.3.3.

NOTE 2: Method b) allows for cases such as when the BS is sending a group-addressed instruction to return to the appropriate common control channel to a group that includes both CA MSs and DA MSs and/or that includes DA MSs from more than one DA cell sharing the assigned channel.

EXAMPLE: If the BS is sending a group-addressed instruction to return to the appropriate common control channel to a group that includes both CA MSs and DA MSs sharing the assigned channel, it should use a non-augmented channel allocation (including the CA main carrier number).

If the BS is sending a group-addressed instruction to return to the appropriate common control channel to a group that includes DA MSs from more than one DA cell sharing the assigned channel, it should use a non-augmented channel allocation (and should set the carrier number to zero).

NOTE 3: The BS is also permitted to use a non-augmented channel allocation (setting the carrier number to zero) when it is sending an individually-addressed instruction to return to the appropriate common control channel to a DA MS.

NOTE 4: If the BS is sending an instruction to return to the appropriate common control channel to a DA MS (or DA MSs), and the DA main carrier has moved while the MS (or MSs) have been on the assigned channel, the BS should use an augmented QAM channel allocation if possible.

An assigned channel may comprise one or more timeslots per TDMA frame, as indicated by the bit map in element "timeslot assigned".

For "allocation type" = 11<sub>2</sub> (i.e. Replace + CSS channel), the "timeslot assigned" element shall indicate only those slots belonging to the assigned channel. Thus, if the specified carrier is not the MS's main carrier, the first bit in the bit map shall be 0 (bit map = 0xxx<sub>2</sub>); the use of slot 1 for the CSS channel is implicit. For CA, if the specified carrier is the MS's main carrier, the bit corresponding to the MS's common channel shall be 0.

NOTE 5: The designation of whether the MS-MAC regards the channel as "assigned" or "common" affects the random access and channel maintenance procedures, and whether energy economy (or part-time reception) mode or napping mode may be appropriate.

If the BS assigns slot 1 of a CA main carrier for a circuit mode call, it should send a channel allocation command to those users. This may not cause a change of carrier or timeslot; but it is needed to change the MAC mode from "common" to "assigned", and also to define monitoring pattern information and a traffic usage marker. A similar procedure applies if the BS wishes to allow an MS that is receiving a CSS channel to use slot 1 of that carrier for a circuit mode call or as a fully assigned SCCH.

If the BS assigns the timeslot or timeslots used for the MCCH-Q (or the timeslot used for a QAM common SCCH) as an assigned SCCH for an MS or MSs, it should send a channel allocation command to those users. This may not cause a change of carrier or timeslot; but it is needed to change the MAC mode from "common" to "assigned". There will usually also be other MSs still in common mode on the MCCH-Q or common SCCH.

### 23.5.4.3.3 Use of "up/downlink assigned" and "Up/downlink assigned for augmented channel allocation"

The "Up/downlink assigned" element in the channel allocation is used in two ways:

- values 01<sub>2</sub>, 10<sub>2</sub> and 11<sub>2</sub> indicate whether either or both directions on the allocated channel have been assigned exclusively for the usage required by the MS;
- value 00<sub>2</sub> indicates that this is an augmented channel allocation; then conditional element "Up/downlink assigned for augmented channel allocation" indicates whether either or both directions on the allocated channel have been assigned exclusively for the usage required by the MS.

The MS-MAC shall note, from element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation", whether either or both directions on the allocated channel have been assigned exclusively for the usage required by the MS.

This information generally affects only the channel maintenance procedure. In the case of independent allocation of uplink and downlink for different purposes, reduced procedures shall apply; see clause 23.5.6.

However, for the application of the general procedures for transmission and reception of signalling messages, each control channel (ACCH or SCCH) shall be assumed to occupy any control slots on both the downlink and uplink directions, as indicated by element "timeslot assigned".

**EXAMPLE:** The MS attempts to receive and decode the downlink channel according to the normal procedures for an assigned channel, even if only the uplink was allocated by element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation". Similarly, the normal procedures for random access and reserved access on an assigned channel apply, even if only the downlink was allocated by element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation".

**NOTE 1:** The up/downlink assigned designation (from either element) is included to allow the BS to use independent allocation of uplink and downlink i.e. allocating the uplink and downlink channels for different purposes (as described in clause 23.3.4).

**NOTE 2:** For "allocation type" = 11<sub>2</sub>, the up/downlink assigned designation applies only to the assigned channel. Allocation of only one direction of a CSS channel does not apply.

MSs that support D8PSK and/or QAM operation need to support the augmented channel allocation in order to be allocated to a D8PSK or QAM channel. It is optional whether an MS that only supports  $\pi/4$ -DQPSK operation supports the augmented channel allocation (see "class of MS" element in clause 16). If an MS that does not support augmented channel allocations receives a channel allocation with the "Up/downlink assigned" element set to 00<sub>2</sub>, the MS-MAC shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation.

The currently defined values of the "Up/downlink assigned for augmented channel allocation" element are values 01<sub>2</sub>, 10<sub>2</sub> and 11<sub>2</sub>; value 00<sub>2</sub> is reserved in the present document. If the MS-MAC receives an augmented channel allocation with the "Up/downlink assigned for augmented channel allocation" element set to 00<sub>2</sub>, it shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation.

#### 23.5.4.3.4 CLCH(-Q) permission

If the "CLCH(-Q) permission" flag indicates "Immediate CLCH(-Q) permission" and the MS makes an immediate decision to accept the channel allocation then the MS may use the first subslot of the first uplink slot on the allocated channel for linearization, without needing to receive the corresponding ACCESS-ASSIGN PDU. The first uplink slot on the allocated channel is as defined in procedure 1) of clause 23.5.4.3.1 i.e. as defined for an immediate decision. The MS uses CLCH if the allocated channel is a  $\pi/4$ -DQPSK or D8PSK channel, or CLCH-Q if the allocated channel is a QAM channel.

Otherwise, if the MS requires to use CLCH or CLCH-Q for linearization, it shall wait for an appropriate frame 18 or for an ACCESS-ASSIGN PDU indicating a linearization subslot.

**NOTE 1:** The "CLCH(-Q) permission" flag is included to allow for fast call set-up with a change of RF carrier while still allowing flexibility for the BS, e.g. in cases of independent allocation of uplink and downlink or repeat set-up signalling for a group call. The BS should at least give CLCH(-Q) permission to any MSs that have indicated that they need to use:

- CLCH for linearization, if the allocated channel is a  $\pi/4$ -DQPSK or D8PSK channel; or
- CLCH-Q for linearization, if the allocated channel is a QAM channel,

and that are granted slots and/or given transmit permission on a new carrier. The CLCH(-Q) permission applies to any MS that obeys the channel allocation message without delay, whether or not it has been granted slots and/or transmit permission.

The MS indicates whether it needs to use CLCH for linearization on carrier change in the "class of MS" element; see clause 16. The MS indicates whether it needs to use CLCH-Q for linearization on carrier change in the "QAM capabilities" element; see clause 16.

**NOTE 2:** For "allocation type" = 11<sub>2</sub>, the CLCH(-Q) permission applies only to the assigned channel, not to the CSS channel.

**NOTE 3:** In the case of a delayed decision to accept a group addressed channel allocation, the MS may use the CLCH(-Q) permission if it is capable of calculating the time of the first uplink slot of the allocated channel based on an immediate decision and the higher layers accept the channel allocation before that time occurs.

### 23.5.4.3.5 Monitoring pattern information

The MS shall note the monitoring pattern information in case it is required to transmit user traffic on this channel. This requirement to store the monitoring pattern information applies to any MS that obeys the channel allocation message, whether or not it has been given permission to transmit user traffic at this time.

The monitoring pattern information indicates in which downlink frames the MS is required to receive downlink slots and attempt to decode any signalling messages (within the capabilities of that MS) while it is transmitting traffic. This enables the BS to send signalling messages to that MS during its traffic transmission. See clause 9 for the definition of the usage of the monitoring pattern numbers; see also clause 21.5.2.

In the case that no monitoring pattern is assigned, an additional field defines the multiframe(s) in which the MS shall receive and attempt to decode the downlink assigned slot in frame 18 (or, for a multi-slot channel, at least the highest numbered downlink slot of the assigned channel in frame 18).

The requirements for the MS to adhere to the assigned monitoring pattern(s) are only within the capabilities of that MS. The BS should note those capabilities when sending signalling messages to an MS that is transmitting traffic on a multi-slot channel (see clauses 23.3.1.3 and 23.3.1.4).

- NOTE 1: When the BS allocates a multi-slot channel to a frequency half duplex MS, it is not precluded from assigning monitoring pattern(s) that the MS cannot observe. For example, this may be convenient if the BS assigns the monitoring pattern information in a group addressed channel allocation, where the group contains both frequency full duplex and frequency half duplex MSs. However the BS should be aware that a frequency half duplex MS without fast switching capability is not able to receive signalling on the downlink between transmitted bursts on the uplink.
- NOTE 2: The monitoring pattern information refers to the requirements on an MS that is transmitting traffic to receive the downlink of the current channel. This is not the same as the "monitoring procedure" defined in clause 23.7.4, in which the MS measures the signal strength of adjacent cells or irregular channels (or the main carrier of the serving cell) and calculates C2.
- NOTE 3: The BS designer should note that the assignment of all three monitoring patterns to a frequency half duplex MS in a simplex call may reduce that MS's ability to perform cell reselection measurements on adjacent cells while it is transmitting traffic. The BS designer should also note that the assignment of all three monitoring patterns to a frequency half duplex dual watching MS may reduce that MS's ability to perform dual watch on the Direct Mode RF carrier during V+D calls.
- NOTE 4: For "allocation type" = 11<sub>2</sub>, the monitoring pattern information applies only to the assigned channel, not to the CSS channel.

### 23.5.4.3.6 Bandwidth, modulation mode and related parameters

The "channel allocation" element allows the BS to make an augmented channel allocation. An augmented channel allocation is indicated by setting the "Up/downlink assigned" element to 00<sub>2</sub>.

If the channel allocation is not augmented (i.e. element "Up/downlink assigned" ≠ 00<sub>2</sub>):

- a CA MS shall assume that the allocated channel is a 25 kHz  $\pi/4$ -DQPSK conforming channel and that the BS transmit power on the allocated channel relative to the CA main carrier is 0 dB;
- if element "timeslot assigned" ≠ 0000<sub>2</sub>, a DA MS shall assume that the allocated channel is a 25 kHz  $\pi/4$ -DQPSK conforming channel and that the BS transmit power on the allocated channel relative to the DA main carrier is 0 dB;
- if element "timeslot assigned" = 0000<sub>2</sub>, a DA MS shall make the assumptions specified in clause 23.5.4.3.2.

If the channel allocation is augmented (i.e. element "Up/downlink assigned" = 00<sub>2</sub>), elements "bandwidth of allocated channel" and "modulation mode of allocated channel" shall indicate the bandwidth of the allocated channel and whether the allocated channel is a  $\pi/4$ -DQPSK, D8PSK or QAM channel; see note 10.

- NOTE 1: In the case of a  $\pi/4$ -DQPSK or D8PSK channel, the bandwidth of the allocated channel is 25 kHz. In the case of a QAM channel, the bandwidth of the allocated channel is 25 kHz, 50 kHz, 100 kHz or 150 kHz.

If the allocated channel is a QAM channel, the "maximum uplink QAM modulation level" element shall indicate the maximum modulation level that the MS is permitted to use on the uplink. If the MS does not understand the value of the "maximum uplink QAM modulation level" element, it shall regard the value as indicating the maximum QAM modulation level supported by that MS.

NOTE 2: If the allocated channel is an assigned channel, the MS continues to use the value of the "maximum uplink QAM modulation level" element from the channel allocation while on that assigned channel.

The SYSINFO-DA PDU indicates the maximum uplink QAM modulation level to be used on common control channels on the DA main carrier. Therefore, if the allocated channel is the common control channel, a DA MS updates the maximum uplink QAM modulation level when it receives the SYSINFO-DA PDU on the common control channel.

Then the "conforming channel status" element shall indicate whether the allocated channel is a conforming channel, non-conforming concentric channel, sectored channel, super-sectored channel or eccentric channel; see note 5 and note 10.

NOTE 3: As described in clause 23.7, a "concentric channel" has essentially the same azimuthal radiation pattern as the main carrier and is radiated from the same site as the main carrier. A "conforming channel" is a concentric channel that has essentially the same range as the main carrier. A "non-conforming concentric channel" is a concentric channel that has a larger or smaller range than the main carrier. A "sectored channel" has an azimuthal extent that is smaller than, and contained entirely within, the azimuthal extent of the main carrier, and is radiated from the same site as the main carrier; it is a non-conforming channel and is not a concentric channel. A "super-sectored channel" has an azimuthal extent that exceeds the azimuthal extent of the main carrier in at least one azimuthal direction, and is radiated from the same site as the main carrier; it is a non-conforming channel and is not a concentric or sectored channel. An "eccentric channel" is a channel that is not radiated from the same site as the main carrier; it is a non-conforming channel and is not a concentric, sectored or super-sectored channel.

NOTE 4: When the MS receives a channel allocation directing it to a channel on a new cell, it should regard the "conforming channel status" as being defined relative to the main carrier of the new cell.

NOTE 5: If element "conditional element A" is included in the channel allocation, a DA MS uses the "DA conforming channel status" element from element "conditional element A" instead of using the "conforming channel status" element; see clause 23.5.4.3.8 and clause 23.5.4.3.9.

If the MS does not understand the value of the "conforming channel status" element and the MS accepts the channel allocation:

- i) the MS cannot perform assessment of the main carrier based on measurements made on the allocated channel; therefore the MS shall perform monitoring of the main carrier (path loss parameter C2) instead of performing assessment of the main carrier (path loss parameter C3); see clause 23.7;
- ii) similarly the MS cannot perform assessment of channel classes based on measurements made on the allocated channel; therefore, if the MS wishes to perform assessment of channel classes, it shall perform main carrier monitoring with assessment of channel classes (path loss parameter C5) instead of performing serving cell channel class assessment (path loss parameter C4).

DA MSs shall be capable of performing the additional monitoring described in i) and ii) above, whereas it is optional for CA MSs to be capable of performing this additional monitoring. If a CA MS does not understand the value of the "conforming channel status" element and is not capable of performing this additional monitoring, the MS is not capable of using the allocated channel and shall not accept the channel allocation. (Therefore, for example, for a channel replacement received on an assigned channel, the MS normally returns to its common control channel; see clause 23.5.4.2.3.)

NOTE 6: Thus, if the "conforming channel status" element is set to one of the reserved values, the MS may accept the channel allocation provided that the MS performs the additional monitoring described in i) and ii) above.

The MS shall also perform the additional monitoring described in i) and ii) above if it accepts a channel allocation for which the "conforming channel status" indicates that the allocated channel is a super-sectored or eccentric channel; see clause 23.7. DA MSs shall be capable of performing this additional monitoring, whereas it is optional for CA MSs to be capable of performing this additional monitoring. If a CA MS is not capable of performing this additional monitoring, the MS is not capable of using the allocated channel and shall not accept the channel allocation.

The "BS link imbalance" element contains information that may be used by the MS in its link adaptation algorithm if the allocated channel is a D8PSK or QAM channel (see clause 23.4.9); see note 7 and note 10.

NOTE 7: If the allocated channel is an assigned channel, the MS continues to use the value of the "BS link imbalance" element from the channel allocation while on that assigned channel.

The SYSINFO-DA PDU indicates the BS link imbalance value to be used on common control channels on the DA main carrier. Therefore, if the allocated channel is the common control channel, a DA MS updates the BS link imbalance value when it receives SYSINFO-DA on the common control channel.

The "BS transmit power relative to main carrier" element shall indicate the BS transmit power (ERP) on the allocated channel; see note 8, note 9 and note 10.

NOTE 8: When the MS receives a channel allocation directing it to a channel on a new cell, it should regard the "BS transmit power relative to main carrier" as being defined relative to the main carrier of the new cell.

NOTE 9: If element "conditional element A" is included in the channel allocation, a DA MS calculates the BS transmit power on the allocated channel using the "BS transmit power relative to current carrier" element from element "conditional element A" instead of using the "BS transmit power relative to main carrier" element; see clause 23.5.4.3.8 and clause 23.5.4.3.9.

NOTE 10: If element "timeslot assigned" = 0000<sub>2</sub>, and the channel allocation is augmented but the modulation mode does not indicate QAM, a DA MS makes the assumptions specified in clause 23.5.4.3.2.

NOTE 11: For "allocation type" = 11<sub>2</sub>, the "modulation mode of allocated channel" information applies only to the assigned channel, not to the CSS channel; a CSS channel is always a  $\pi/4$ -DQPSK channel. In the present document, use of "allocation type" 11<sub>2</sub> is not appropriate when the BS is allocating a QAM channel.

NOTE 12: In the present document, if an MS receives "allocation type" 11<sub>2</sub> when the BS is allocating a QAM channel, the MS should regard the allocation as "allocation type" 00<sub>2</sub> (replace current channel with specified channel).

#### 23.5.4.3.7 Napping status and napping information

If the channel allocation is augmented (i.e. element "Up/downlink assigned" = 00<sub>2</sub>), the "napping status" element shall indicate whether napping is permitted on the allocated channel:

- if "napping status" = 00<sub>2</sub>, the MS shall assume that use of the napping procedure is not permitted on the allocated channel;
- if "napping status" = 01<sub>2</sub>, the MS shall assume that use of the napping procedure is permitted on the allocated channel, using the napping parameters specified in the "napping information" element;
- if "napping status" = 10<sub>2</sub>, the MS shall assume that use of the napping procedure is permitted on the allocated channel, using the napping parameters for the current channel (i.e. the channel on which the channel allocation was received).

If the channel allocation is not augmented (i.e. element "Up/downlink assigned"  $\neq$  00<sub>2</sub>), the MS shall assume that use of the napping procedure is not permitted on the allocated channel.

NOTE 1: Napping may apply only when the MS has accepted a channel allocation for an assigned channel. It does not apply to MSs that are in common mode.

In some cases some MSs may be in assigned mode on a physical channel (or physical channels) while other MSs may be in common mode on that physical channel (or physical channels). Napping may apply only to those MSs that are in assigned mode.

NOTE 2: For "allocation type" = 11<sub>2</sub>, the "napping status" and "napping information" apply only to the assigned channel, not to the CSS channel. Use of the napping procedure does not apply on a CSS channel.

### 23.5.4.3.8 Elements following napping status and napping information

If the channel allocation is augmented (i.e. element "Up/downlink assigned" = 00<sub>2</sub>), the channel allocation includes the following elements following the "napping status" or "napping information" element:

- a four-bit reserved element (set to zero in the present document);
- a flag (named "conditional element A flag") indicating whether a first 16-bit conditional element is present, and the conditional element (named element "conditional element A") if appropriate; if present, element "conditional element A" contains:
  - element "DA conforming channel status" (see clause 23.5.4.3.9);
  - element "BS transmit power relative to current carrier" (see clause 23.5.4.3.9); and
  - an eight-bit reserved element (set to zero in the present document);
- a flag (named "conditional element B flag") indicating whether a second 16-bit conditional element is present; this flag shall be set to 0 in the present document, to indicate that element "conditional element B" is not present;
- a flag indicating further augmentation of the channel allocation (allowing for future further extension).

The reserved elements allow for inclusion of future information in the channel allocation, while still allowing MSs that do not understand that information to process and obey the channel allocation. The reserved elements (when present) are set to zero in the present document. However the MS may continue to process the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU, and may obey the channel allocation, if these elements are not set to zero.

"Conditional element B" also allows for inclusion of future information in the channel allocation, while still allowing MSs that do not understand that information to process and obey the channel allocation. The "conditional element B flag" shall be set to 0 in the present document, indicating that element "conditional element B" is not present. However, if the MS receives a channel allocation with "conditional element B flag" set to 1, it shall assume that a 16-bit element is included following the "conditional element B flag"; the MS may then continue to process the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU, and may obey the channel allocation.

The further augmentation flag allows for inclusion of future additional information whose size is not defined in the present document. The further augmentation flag shall be set to 0 in the present document. If the MS receives a channel allocation with the further augmentation flag set to 1, it shall discard the channel allocation and any TM-SDU carried in the MAC-RESOURCE or MAC-END PDU that contained the channel allocation.

### 23.5.4.3.9 DA conforming channel status and BS transmit power relative to current carrier

If the channel allocation is augmented (i.e. element "Up/downlink assigned" = 00<sub>2</sub>), the channel allocation includes the "conforming channel status" element and "BS transmit power relative to main carrier" element (see clause 23.5.4.3.6). These elements are used by all CA MSs. They are also used by DA MSs if element "conditional element A" is not present in the channel allocation (see clause 23.5.4.3.8).

However, if element "conditional element A" is included in the channel allocation, a DA MS:

- a) shall use the "DA conforming channel status" element from element "conditional element A" as the conforming channel status of the allocated channel instead of using the "conforming channel status" element; and
- b) shall calculate the BS transmit power on the allocated channel using the "BS transmit power relative to current carrier" element from element "conditional element A" instead of using the "BS transmit power relative to main carrier" element.

The MS already knows the BS transmit power of the current channel relative to its main carrier. It shall then calculate the BS transmit power of the allocated channel relative to its main carrier as:

$$\begin{aligned} & \text{BS transmit power (of the allocated channel) relative to the current carrier} \\ & + \text{BS transmit power (of the current channel) relative to the main carrier} \end{aligned} \quad (23.7)$$

NOTE 1: The BS should not include "conditional element A" when it is sending a channel allocation directing an MS to a channel on a new cell.

If a DA MS does not understand the value of the "DA conforming channel status" element and the DA MS accepts the channel allocation:

- i) the MS cannot perform assessment of the main carrier based on measurements made on the allocated channel; therefore the MS shall perform monitoring of the main carrier (path loss parameter C2) instead of performing assessment of the main carrier (path loss parameter C3); see clause 23.7;
- ii) similarly the MS cannot perform assessment of channel classes based on measurements made on the allocated channel; therefore, if the MS wishes to perform assessment of channel classes, it shall perform main carrier monitoring with assessment of channel classes (path loss parameter C5) instead of performing serving cell channel class assessment (path loss parameter C4).

The MS shall also perform the additional monitoring described in i) and ii) above if it accepts a channel allocation for which the "DA conforming channel status" indicates that the allocated channel is a super-sectored or eccentric channel; see clause 23.7.

DA MSs shall be capable of performing the additional monitoring described in i) and ii) above.

**EXAMPLE:** The BS may need to include element "conditional element A" (therefore including elements "DA conforming channel status" and "BS transmit power relative to current carrier") if it wishes to replace an assigned channel using a group-addressed channel allocation sent to a group that includes MSs from more than one cell (CA cell or DA cell(s)) sharing the assigned channel. (If the group does not include MSs from more than one cell sharing the assigned channel, the BS does not need to include element "conditional element A".)

Use of a group address (possibly the predefined broadcast group address) might be useful, for example, if the BS needs to move the assigned channel or if it wishes to change the number of slots comprising the assigned channel.

NOTE 2: If the BS includes element "conditional element A", and it is sending a group-addressed channel allocation to a group that includes MSs from more than one DA cell sharing the assigned channel, the BS should set the "DA conforming channel status" to the most pessimistic value of conforming channel status appropriate for any of the DA MSs in the group. (For this purpose, eccentric is more pessimistic than super-sectored; super-sectored is more pessimistic than sectored; sectored is more pessimistic than concentric; and non-conforming concentric is more pessimistic than conforming. Thus, in the present document, if the allocated channel is eccentric relative to the DA main carrier for any of the DA MSs in the group, the "DA conforming channel status" is set to "eccentric".)

NOTE 3: In future editions of the present document, the most pessimistic value of conforming channel status may be a value that is currently reserved. MS designers should consider this possibility when deciding whether to implement the monitoring procedure used if the MS accepts a channel allocation containing a value of "DA conforming channel status" that it does not understand.

### 23.5.5 Usage marker assignment

A traffic usage marker is a 6-bit MAC label used during circuit mode calls for transmitter pre-emption, for prevention of crossed calls and for channel maintenance purposes. The BS shall assign a traffic usage marker before any traffic transmission takes place on an assigned channel.

It shall assign the usage marker with a message that contains also a channel allocation command directing MS(s) to an assigned channel. The usage marker assignment shall be valid for that MS (or those MSs) only on that assigned channel. So, for example, for message trunking, one traffic usage marker generally applies for the complete call and the same usage marker should be assigned for all participants in that call on that assigned channel; whereas, for transmission trunking, the BS should assign a traffic usage marker for each "over".

NOTE 1: If the BS wishes to assign a traffic usage marker on an already assigned channel, then it may use the "replace channel" command indicating the current channel. However, when the BS uses a group addressed message to allocate a channel for a circuit mode call, it is recommended that, if possible, it assigns the traffic usage marker when it sends the channel allocation; otherwise the usage marker may not be received by those MSs that do not make an immediate decision to accept the channel allocation.

NOTE 2: For "allocation type" = 11<sub>2</sub>, the usage marker applies only to the assigned channel, not to the CSS channel.

When there is traffic (TCH or STCH) on either the uplink or the downlink, the BS shall use the appropriate traffic usage marker in the ACCESS-ASSIGN PDU sent on the AACH in frames 1 to 17 on the downlink assigned channel to confirm permission to transmit and/or receive traffic. For uplink traffic, Header 11<sub>2</sub> shall be used, with "Field 2" set to the uplink traffic usage marker. For downlink traffic, Header 01<sub>2</sub>, 10<sub>2</sub> or 11<sub>2</sub> shall be used, with "Field 1" set to the downlink traffic usage marker.

A traffic usage marker may also be sent in the ACCESS-ASSIGN PDU in frame 18, though frame 18 is never used for TCH or STCH. Then the frame 18 Header shall be set to 11<sub>2</sub> and the usage marker in "Field 1" may be set to either the uplink or downlink traffic usage marker as appropriate. This can be useful for channel maintenance purposes. And, during uplink traffic, it should be used with the traffic usage marker of the transmitting MS if the BS has not assigned a monitoring pattern for frames 1 to 17 (or, for a multi-slot channel, if the BS has assigned monitoring pattern(s) that the MS may not be capable of following in any slots in frames 2 to 17).

The procedures for channel maintenance by the MS-MAC, and the criteria for MS transmission and reception of traffic, are described in clauses 23.5.6 and 23.8.2 respectively.

When the BS wishes to assign a traffic usage marker, it shall use the MAC-RESOURCE PDU, which shall contain "Address Type" = 110<sub>2</sub> and the assigned traffic usage marker. The "channel allocation" element shall be included in that MAC-RESOURCE PDU or in the associated MAC-END PDU. If the MS-MAC receives a usage marker assignment without the corresponding channel allocation (e.g. in the case of fragmentation if the MS does not receive the MAC-END PDU), or if it does not obey the channel allocation, then it shall ignore the usage marker assignment.

A traffic usage marker shall apply for the direction(s) specified in the channel allocation, i.e. the appropriate direction for element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" = 01<sub>2</sub> or 10<sub>2</sub>, or both directions for element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" = 11<sub>2</sub>. If the BS uses independent allocation of the uplink and downlink for two circuit mode calls then the traffic usage marker should be different for the two directions.

In the case of independent allocation of the uplink and downlink of a channel for concurrent calls involving the same MS, the MS-MAC may receive independent channel allocations of uplink and downlink, each with a usage marker assignment. Each usage marker shall apply independently for the specified direction. (However, the same endpoint identifier applies for both allocations when the allocations are for the same assigned channel.)

The MS-MAC shall consider that an assigned traffic usage marker is valid until:

- i) it leaves the assigned channel (or returns to common mode on this channel); or
- ii) it receives another traffic usage marker with a channel allocation for the same direction(s) or for both directions on the same assigned channel; or
- iii) it receives a channel allocation for the same direction(s) or for both directions on the same assigned channel, but without a usage marker assignment.

The BS is responsible for deciding when a traffic usage marker may safely be re-used for a subsequent call on the same physical channel.

## 23.5.6 Maintenance of assigned channel

### 23.5.6.0 General

The MS shall receive its common control channel (i.e. the MCCH or MCCH-Q, or the appropriate  $\pi/4$ -DQPSK or QAM common SCCH) unless directed by the BS to an assigned channel. An assigned channel may be intended for secondary control purposes or for a circuit mode call. The MS shall assume that the assigned channel is intended for secondary control unless it has received a traffic usage marker for use on the channel.

The ACCH is the control channel associated with an assigned traffic channel. When ACCH is present, its usage is similar to the usage of assigned SCCH, and there is no distinction in the pre-set usage marker designation in the ACCESS-ASSIGN PDU. Both types of control channel shall be regarded as assigned control channel. The traffic usage marker is generally used only while the channel is carrying user traffic TCH or STCH.

The procedures for channel maintenance defined in clause 23.5.6.1 apply on either type of assigned channel, unless specified otherwise.

The procedures for maintenance of a CSS channel are reduced compared with those for a normal assigned channel. They are defined in clause 23.5.6.2.

### 23.5.6.1 Criteria for leaving assigned channel

#### 23.5.6.1.0 General

**NOTE:** This clause applies to MSs that are in assigned mode, having accepted a channel allocation for an assigned channel. In some cases other MSs may be in common mode on that channel, in which case those other MSs obey the maintenance procedures for a common channel; see clause 23.5.7.

The MS-MAC shall continue to receive and attempt to decode signalling on the downlink assigned channel as defined by element "timeslot assigned" (within the constraints of the napping procedures and the cell reselection procedures, and monitoring pattern requirements, and linearization and transmission requirements) until one of the following occurs:

- the MS-MAC obeys a channel allocation command from the BS, directing it elsewhere (see clause 23.5.4); or
- the MS is required to leave the channel by one of the channel maintenance procedures in clauses 23.5.6.1.1 and 23.5.6.1.2; or
- the MS-MAC receives a TMC-SELECT request primitive from the higher layers instructing it to leave the assigned channel; or
- the MS-MAC receives a TMC-CONFIGURE request primitive from the higher layers indicating call release for this channel, e.g. the user wishes to leave a group call.

In the last case, the MS should not leave the channel if it has been assigned both directions of the channel in two independent allocations of uplink and downlink, and if the service on the other direction is still ongoing.

#### 23.5.6.1.1 Checking of AACH or AACH-Q

The MS shall attempt to decode:

- the AACH, on a  $\pi/4$ -DQPSK or D8PSK channel; or
- the AACH-Q, on a QAM channel;

in slots appropriate to the downlink assigned channel as defined by element "timeslot assigned" (within the constraints of the napping procedures and the cell reselection procedures, and monitoring pattern requirements, and linearization and transmission requirements).

The AACH always contains the ACCESS-ASSIGN PDU. The AACH-Q may contain the ACCESS-ASSIGN PDU (depending on the value of the "AACH-Q mode" element - see clause 21.4.7.1).

If N.208 successive ACCESS-ASSIGN PDUs received in frames 1 to 17 in the AACH or AACH-Q of slots appropriate to the downlink assigned channel indicate that:

- a) the downlink is unallocated, i.e. Header  $\neq 00_2$  and downlink usage marker = UMx (000000<sub>2</sub>); or
- b) the channel has returned to exclusively common control use, i.e. Header = 00<sub>2</sub>; or
- c) the relevant direction(s) have been assigned for another purpose (see below);

then the MS shall regard the assigned channel as no longer valid for transmission or reception. Then, if the MS does not have a concurrent assigned channel, it shall return to its common control channel. The MS-MAC shall inform the higher layers of the de-allocation using either:

- the TMA-RELEASE indication primitive to indicate loss of the connection; or
- a TMC-CONFIGURE indication primitive indicating loss of the physical resource;

and shall inform the higher layers of any change of channel using the TMC-SELECT indication primitive.

NOTE 1: When the LLC receives the TMA-RELEASE indication primitive, it locally disconnects any advanced links on that resource (see clause 22.3.3.4). When the LLC receives the TMC-CONFIGURE indication primitive indicating loss of the physical resource, it may retain any advanced links on that resource for potential continuation (see clause 22.3.5).

For criterion c), the MS shall check as follows:

- If the downlink was assigned for this MS (element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" =  $01_2$  or  $11_2$ ), the MS shall regard the assigned channel as no longer valid if:
  - for a  $\pi/4$ -DQPSK or D8PSK assigned SCCH:
 

the downlink is not in assigned control i.e. the channel is no longer valid if Header =  $00_2$  or if the downlink usage marker  $\neq 000001_2$ ;
  - for a QAM assigned SCCH:
 

the downlink is not in assigned control nor in common and assigned control i.e. the channel is no longer valid if Header =  $00_2$  or if the downlink usage marker is neither  $000001_2$  nor  $000011_2$  (see note 8);
  - for a circuit mode call:
 

the downlink is not in assigned control nor in traffic with the MS's usage marker i.e. the channel is no longer valid if Header =  $00_2$  or if the downlink usage marker is neither  $000001_2$  nor the MS's downlink traffic usage marker.
- If the uplink was assigned for this MS (element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" =  $10_2$  or  $11_2$ ), the MS shall regard the assigned channel as no longer valid if:
  - for assigned SCCH:
 

the uplink is unallocated or is being used for traffic i.e. the channel is no longer valid if Header =  $11_2$  and the uplink usage marker =  $000000_2$  or is  $\geq 000100_2$ ;
  - for a circuit mode call:
 

the uplink is unallocated or is being used for traffic by other users i.e. the channel is no longer valid if Header =  $11_2$  and the uplink usage marker =  $000000_2$  or is  $\geq 000100_2$  and is not the MS's uplink traffic usage marker.

If the MS has been assigned both directions of the channel in two independent channel allocations then it shall not leave the channel on criterion c) unless both directions are no longer valid according to the above definition. Whereas, if the MS has been assigned both directions of the channel in a single channel allocation (i.e. with element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" =  $11_2$ ) then it shall leave the channel on criterion c) if either direction is no longer valid.

NOTE 2: The MS should not react to reception of only one adverse ACCESS-ASSIGN PDU, because of the possibility of incorrectly decoding the AACH or AACH-Q. So  $N.208 \geq 2$ .

NOTE 3: The value of N.208 may be different on a QAM channel from the value on a  $\pi/4$ -DQPSK or D8PSK channel.

NOTE 4: The N.208 procedure refers to a check on those ACCESS-ASSIGN PDUs that are received by the MS, irrespective of whether or not these are in successive slots on the assigned channel. On a  $\pi/4$ -DQPSK or D8PSK channel, the MS does not receive the ACCESS-ASSIGN PDU in a downlink slot if the AACH is not decodeable. On a QAM channel, the MS does not receive the ACCESS-ASSIGN PDU in a downlink slot if either the AACH-Q is not decodeable or the ACCESS-ASSIGN PDU is not present within the AACH-Q.

NOTE 5: For this procedure, the MS checks only the designation of slots belonging to the downlink assigned channel (although, in the case of an extended random access channel, the MS may be decoding other ACCESS-ASSIGN PDUs).

NOTE 6: As a result of de-allocation on criterion b) or c), the MS may actually remain on the same physical channel. However, its designation has changed from "assigned" to "common".

NOTE 7: If the BS has assigned only the uplink in a channel allocation, and the downlink is not used for another purpose, the BS should mark the downlink as "assigned control" in the ACCESS-ASSIGN PDU, not "unallocated". Similarly, the BS should not use Header 00<sub>2</sub> unless the channel is entirely dedicated to common control usage.

NOTE 8: Downlink usage marker 000001<sub>2</sub> may be used on  $\pi/4$ -DQPSK, D8PSK and QAM channels; it indicates "assigned control". Downlink usage marker 000011<sub>2</sub> may be used on QAM channels; it indicates "common and assigned control". Therefore the MS regards both values 000001<sub>2</sub> and 000011<sub>2</sub> as valid downlink usage markers on a QAM assigned SCCH.

#### 23.5.6.1.2 Inactivity time-out

If the MS is on a channel assigned for SCCH, and a time T.208 elapses without either:

- transmission by the MS by reserved access; or
- receipt of a downlink message on this channel containing one of its valid addresses or event labels, other than the predefined broadcast group address (all ones),

then the MS shall regard the channel as no longer valid for transmission or reception.

If the MS is on a channel assigned for a circuit mode call, and a time T.209 elapses without either:

- transmission by the MS, for traffic (TCH or STCH) or by reserved access; or
- receipt of a downlink message on this channel containing one of its valid addresses or event labels, other than the predefined broadcast group address (all ones); or
- receipt of an ACCESS-ASSIGN PDU containing the MS's traffic usage marker (either as the downlink or the uplink usage marker in the ACCESS-ASSIGN PDU, and in any frame 1 to 18),

then the MS shall regard the channel as no longer valid for transmission or reception.

In case of time-out on either T.208 or T.209 then, if the MS does not have a concurrent assigned channel, it shall return to its common control channel. The MS-MAC shall inform the higher layers of the de-allocation using either:

- the TMA-RELEASE indication primitive to indicate loss of the connection; or
- a TMC-CONFIGURE indication primitive indicating loss of the physical resource,

and shall inform the higher layers of any change of channel using the TMC-SELECT indication primitive.

NOTE 1: In order to keep MSs on the channel during long periods of FACCH, e.g. for an open channel, the BS may send occasional slots in frames 1 to 17 containing the traffic usage marker as the uplink usage marker (with Header 11<sub>2</sub>); or it may use the traffic usage marker as the usage marker in frame 18 (frame 18 Header 11<sub>2</sub>). Also, use of the traffic usage marker as the downlink usage marker in occasional slots in frames 1 to 17 (with STCH + STCH) is not precluded though it is not recommended. Otherwise the BS could send dummy messages addressed to the MS(s) on the channel.

NOTE 2: If the MS decides to obey a group addressed channel allocation after a delay then it may choose to decrease its value of T.208 or T.209 until it has received signalling confirming that the expected service is still ongoing on the assigned channel i.e. until it has received an appropriate downlink message addressed to itself or ACCESS-ASSIGN PDU(s) containing its traffic usage marker. Similarly, in clause 23.5.6.1.1, the MS is not precluded from reducing its value of N.208 though it should not reduce N.208 to below 2.

### 23.5.6.2 Criteria for leaving carrier specific signalling channel

This clause applies to MSs that are on a CSS channel, having accepted the CSS part of a channel allocation with allocation type 11<sub>2</sub> (Replace + CSS channel) where the allocated carrier is not the MS's main carrier.

After assignment of a CSS channel, the MS-MAC may continue to use the CSS channel on that carrier until one of the following occurs:

- a) it obeys a channel allocation command received on that CSS channel, directing it elsewhere (see clause 23.5.4.2.4); or
- b) it has no assigned channel on that carrier, assigned either for SCCH or for a circuit mode call; or
- c) it obeys a channel allocation command allocating slot 1 of that carrier as an assigned channel.

The MS-MAC should inform the higher layers of the de-allocation of the CSS channel and of any change of channel.

EXAMPLE: In criterion a), the MS leaves the CSS channel if it obeys a "replace" channel allocation received on the CSS channel, or if it obeys a "replace + CSS channel" allocation received on the CSS channel and assigning a different carrier, or if it receives and does not ignore a "quit" channel allocation received on the CSS channel.

Criterion b) requires the MS to leave the CSS channel when it no longer has an assigned channel (other than the CSS channel) on that carrier.

If criterion c) occurs, the MS remains on the same physical channel (i.e. slot 1 of the carrier). However, its usage of the physical channel has changed from CSS channel to assigned channel.

NOTE 1: Criterion a) only requires the MS to leave the CSS channel. It does not require the MS to leave the assigned channel that was allocated in the same channel allocation as the CSS channel (unless the MS is no longer capable of receiving that assigned channel as a result of obeying the channel allocation command).

NOTE 2: Criterion b) requires the MS to leave the CSS channel when it has no assigned channel on that carrier. Thus the permission to use the CSS channel is not specifically linked to the assigned channel that was allocated in the same channel allocation as the CSS channel. If the MS leaves that assigned channel then it may continue to use the CSS channel if it has another assigned channel on the carrier.

### 23.5.6.3 Traffic on downlink for other users

When the MS is receiving a  $\pi/4$ -DQPSK assigned channel, the downlink may be used for traffic independently of any usage of the uplink for signalling or traffic. For example:

- uplink assigned for SCCH, but with downlink not dedicated to SCCH;
- inter-site circuit mode call.

An MS is specifically instructed when it may process received user traffic TCH for transfer to its U-plane application, as described in clause 23.8.2.

An MS that has not received such authorization shall interpret the downlink slots as follows.

The MS shall assume that a downlink slot in frames 1 to 17 is in traffic mode carrying traffic for other MSs if the ACCESS-ASSIGN PDU contains a downlink traffic usage marker (i.e. Header  $\neq$  00<sub>2</sub> and downlink usage marker  $\geq$  000100<sub>2</sub>). Otherwise it shall assume that the downlink is in signalling mode. If the ACCESS-ASSIGN PDU is not received then the MS shall assume that the downlink is in the mode indicated by the last ACCESS-ASSIGN PDU received in frames 1 to 17 in a slot appropriate to the downlink assigned channel. (See clause 19 for the configuration in signalling and traffic mode.)

In both signalling and traffic mode, full ( $SF = 0$ ) or half slot ( $SF = 1$ ) downlink transmissions may be used. The slot flag ( $SF$ ) shall correspond to a change between two training sequences, as described in clause 9.

In the case of signalling mode on a  $\pi/4$ -DQPSK channel:

- a) The MS shall interpret slots with  $SF = 0$  as SCH/F.
- b) The MS shall interpret slots with  $SF = 1$  as SCH/HD + SCH/HD.

In the case of traffic mode on a  $\pi/4$ -DQPSK channel:

- a) The MS shall interpret slots with  $SF = 0$  as TCH, and shall ignore that TCH.
- b) For  $SF = 1$ , the MS shall interpret the slot as STCH + TCH or STCH + STCH, depending on the content of the first STCH.

For STCH, the MS shall inspect the MAC header of each PDU in order to:

- discover whether the second half slot is stolen;
- perform PDU dissociation (in the case of C-plane stealing);
- process any C-plane messages addressed to itself.

See clause 23.8.4.2.2 for the method for reception of STCH.

The MS shall ignore the TM-SDU in any MAC-U-SIGNAL PDUs, and the TCH.

Slots containing the synchronization training sequence shall always be interpreted as BSCH + SCH/HD.

Traffic mode applies only to frames 1 to 17. Both MS and BS shall always be in signalling mode on frame 18.

NOTE 1: The above procedure applies to any MS that does not have authorization or "N.213 permission" (see clause 23.8.2.3.2) to receive TCH with this traffic usage marker. This includes an MS that is transmitting traffic in simplex mode, or an MS with a different traffic usage marker, or an MS on assigned SCCH.

NOTE 2: When the BS changes the designation of the downlink channel, it may choose to send a few slots using normal training sequence 2 (i.e.  $SF = 1$ ), to allow for poor reception of the ACCESS-ASSIGN PDU. MS interpretation of SCH/HD and two-half-slot STCH is very similar. At other times, use of SCH/F (with PDU association) is recommended for most C-plane signalling on the downlink, since it is generally more flexible.

## 23.5.7 Maintenance of common channel

The MS shall attempt to decode the AACH or AACH-Q in slots appropriate to the downlink common channel (within the constraints of the cell reselection procedures, and linearization and transmission requirements, and energy economy or dual watch or part-time reception mode).

If N.215 successive ACCESS-ASSIGN PDUs received in frames 1 to 17 in the AACH or AACH-Q of slots appropriate to the downlink common channel indicate that:

- the downlink is unallocated, i.e. header value =  $11_2$  and "field 1" =  $UMx (000000_2)$  and "field 2" =  $UMx (000000_2)$ ,

then the MS should regard the common channel as no longer valid for transmission or reception. The MS-MAC should inform the higher layers of the de-allocation using the "common channel deallocated" TMC-REPORT indication primitive (indicating a downlink failure) in order to initiate the MLE cell reselection procedures (as indicated in clause 18.3.4.5.3).

NOTE 1: This procedure applies to MSs that are in common mode on their common control channel. In some cases other MSs may be in assigned mode on that channel, in which case those other MSs obey the maintenance procedures for an assigned channel.

NOTE 2: The value of N.215 may be different on a QAM common channel from the value on a  $\pi/4$ -DQPSK common channel.

NOTE 3: The N.215 procedure refers to a check on those ACCESS-ASSIGN PDUs that are received by the MS, irrespective of whether or not these are in successive slots on the downlink common channel. On a  $\pi/4$ -DQPSK channel, the MS does not receive the ACCESS-ASSIGN PDU in a downlink slot if the AACH is not decodeable. On a QAM channel, the MS does not receive the ACCESS-ASSIGN PDU in a downlink slot if either the AACH-Q is not decodeable or the ACCESS-ASSIGN PDU is not present within the AACH-Q.

## 23.6 PDU transfer for broadcast messages (TMB-SAP)

### 23.6.1 Broadcast logical channels

#### 23.6.1.1 General

The BS shall transmit broadcast system information on phase modulation carriers (i.e. carriers currently carrying  $\pi/4$ -DQPSK and/or D8PSK channel(s)) using the SYNC PDU transmitted on the BSCH and the SYSINFO PDU transmitted on the BNCH.

NOTE 1: The ACCESS-DEFINE PDU also contains broadcast information relating to random access and is described within clause 23.5.1.

NOTE 2: CA MSs use all the information in the SYNC and SYSINFO PDUs. DA MSs on a  $\pi/4$ -DQPSK or D8PSK channel receive and decode the SYNC and SYSINFO PDUs. However they use only the information appropriate to their operation on the current channel; see clause 23.6.9.

On a phase modulation traffic or control channel, the BSCH and BNCH shall be transmitted in frame 18 using a fixed mapping. The BNCH may also be transmitted during frames 1 to 17 of a control channel, and both BSCH and BNCH may be transmitted on unallocated channels. The precise rules for BSCH and BNCH transmission are described in clause 9.

The BS may send broadcast system information to CA MSs on QAM carriers using the SYSINFO-Q PDU transmitted on the BNCH-Q.

The BS shall transmit DA broadcast system information on DA main carriers using the SYNC-DA PDU transmitted on the BSCH-Q and the SYSINFO-DA PDU transmitted on the BNCH-Q. The SYNC-DA and SYSINFO-DA PDUs are used by DA MSs.

The BS may send DA broadcast system information on QAM carriers other than the DA main carrier using the SYNC-DA PDU transmitted on the BSCH-Q and the SYSINFO-DA PDU transmitted on the BNCH-Q.

On a DA main carrier, the BSCH-Q and BNCH-Q (containing SYSINFO-DA) shall be transmitted in frame 18 using a fixed mapping. The BSCH-Q and BNCH-Q (containing either SYSINFO-DA or SYSINFO-Q) may also be transmitted during frames 1 to 18 of any QAM channel (on both the DA main carrier and QAM carriers other than the DA main carrier); and both BSCH-Q and BNCH-Q may be transmitted on unallocated QAM channels. The precise rules for BSCH-Q and BNCH-Q transmission are described in clause 9.

The BS may send DA broadcast system information to DA MSs on phase modulation carriers using the SYSINFO-DA PDU transmitted on the SCH/F, SCH-P8/HD or SCH-P8/F.

#### 23.6.1.2 CA broadcast logical channels

BSCH and BNCH shall be received and decoded by all MSs wishing to camp or camped on a CA cell. These broadcast PDUs contain essential system information required by an MS to synchronize with and use the facilities of a CA cell.

A CA MS, on receiving and correctly decoding broadcast information, shall remove the MAC header and shall store the parameters contained therein as the serving cell broadcast parameters. (While scanning CA adjacent cells, the MAC may also be required to store the broadcast parameters for those adjacent cells for use in the cell reselection procedures.) The MAC shall then pass the TM-SDU to the MLE. Upon receiving subsequent SYNC or SYSINFO PDUs, the MAC shall update its stored serving cell parameters before passing the MLE data contained in the TM-SDU to the LLC which shall then pass the MLE data transparently to the MLE.

The appropriate MAC primitives for the MAC to pass the MLE data to the LLC are the TMB-SYNC indication and TMB-SYSINFO indication.

NOTE 1: In addition to the TM-SDU, the TMB-SYSINFO indication primitive may include extended services information from the MAC PDU. For example, any information in the SYSINFO PDU about support of data priority by the BS is used by the MAC but is also used by the higher layers (e.g. SNDCP).

The broadcast information in both of these PDUs relates to the system configuration for that CA cell. Therefore, the BSCH and BNCH information transmitted on all carriers belonging to a single CA cell shall be identical (with the exception of the items in note 2). This means that a CA MS may receive the system information on any phase modulation carrier belonging to a CA cell. This includes slot, frame and multiframe number implying that all carriers belonging to a BS shall be synchronized in time (see also clause 7).

NOTE 2: The power control and cell/channel (re-)selection parameters may be different for different channels; see clause 23.6.6. Also the random access parameters may be different on different channels.

NOTE 3: The carriers belonging to a BS are synchronized in time as defined in clause 7.7. However the MS may perceive a larger timing difference between an eccentric carrier and the main carrier than between a non-eccentric carrier and the main carrier, because the timing difference depends additionally on the difference between the MS's distance from the eccentric carrier's transmitter site and the MS's distance from the main carrier's transmitter site; see also clause 7.8.

The BS may transmit broadcast system information to CA MSs on QAM carriers (i.e. carriers currently carrying QAM channel(s)) using the SYSINFO-Q PDU transmitted on the BNCH-Q using SCH-Q/D; see clause 23.6.5. The BNCH-Q may be transmitted in any slot in frames 1 to 18: in the present document, there is no fixed mapping of the SYSINFO-Q PDU on a QAM channel.

Further information about the usage of broadcast messages by CA MSs is contained in clauses 23.6.2, 23.6.3, 23.6.4, 23.6.5 and 23.6.6.

### 23.6.1.3 DA broadcast logical channels

BSCH-Q containing the SYNC-DA PDU and BNCH-Q containing the SYSINFO-DA PDU shall be received and decoded by all MSs wishing to camp on a DA cell. These broadcast PDUs contain essential system information required by an MS to synchronize with and use the facilities of a DA cell.

The information in the SYNC-DA PDU is intended primarily for MSs that are attempting to synchronize with and obtain initial information about the DA cell; the SYNC-DA PDU enables the MS to synchronize with and decide whether it wishes to use a DA cell.

The SYSINFO-DA PDU contains further information needed before the MS can actually use the cell. The SYSINFO-DA PDU also duplicates some of the information from the SYNC-DA PDU so that it contains all the TMB-SAP information needed by DA MSs that are already camped on the DA cell.

Therefore all DA MSs camped on a DA cell shall continue to receive and attempt to decode the SYSINFO-DA PDU. However it is optional whether DA MSs camped on a DA cell continue to decode the BSCH-Q to receive the SYNC-DA PDU.

NOTE 1: The SYSINFO-DA PDU does not contain the colour code (or MCC or MNC), timeslot number, frame number or multiframe number. Therefore the MS uses the colour code and derives its timeslot, frame and multiframe numbering from that last received in a SYNC-DA PDU within that cell.

A DA MS, on receiving and correctly decoding DA broadcast information, shall remove the MAC header and shall store the parameters contained therein as the serving cell broadcast parameters. (While scanning DA adjacent cells, the MAC may also be required to store the broadcast parameters for those adjacent cells for use in the cell reselection procedures.) The MAC shall then pass the TM-SDU to the MLE. Upon receiving subsequent SYSINFO-DA PDUs (and optionally SYNC-DA PDUs), the MAC shall update its stored serving cell parameters before passing the MLE data contained in the TM-SDU to the LLC which shall then pass the MLE data transparently to the MLE.

The appropriate MAC primitives for the MAC to pass the MLE data to the LLC are the TMB-SYNC-DA indication and TMB-SYSINFO-DA indication.

NOTE 2: In addition to the TM-SDU, the TMB-SYNC-DA and TMB-SYSINFO-DA indication primitives may include extended services information from the MAC PDU; also the TMB-SYNC-DA indication primitive may include Location Area (LA) information from the MAC PDU.

The broadcast information in both of these PDUs relates to the system configuration for that DA cell. Therefore, the SYNC-DA and SYSINFO-DA information transmitted on all carriers used by a single DA cell shall be identical (with the exception of the items in notes 3 and 4). This means that a DA MS may receive the system information on any QAM carrier used by a DA cell (see note 5). This includes slot, frame and multiframe number implying that all carriers used by a BS shall be synchronized in time (see also clause 7).

NOTE 3: The power control and cell/channel (re-)selection parameters may be different for different channels; see clause 23.6.11. Also the random access parameters may be different on different channels.

NOTE 4: The full information about the DA downlink main carrier is included in the SYNC-DA PDU when the PDU is sent on a QAM carrier other than the DA main carrier; however it is not included (except the DA main carrier bandwidth) when the PDU is sent on the DA main carrier.

The Location Area (LA) is included in the SYNC-DA PDU when the PDU is sent on the DA main carrier; however it is not included when the PDU is sent on a QAM carrier other than the DA main carrier.

NOTE 5: If an assigned channel is shared by MSs from different DA cells, the BS should not send the SYNC-DA or SYSINFO-DA PDU on that assigned channel.

NOTE 6: The carriers belonging to a BS are synchronized in time as defined in clause 7.7. However the MS may perceive a larger timing difference between an eccentric carrier and the main carrier than between a non-eccentric carrier and the main carrier, because the timing difference depends additionally on the difference between the MS's distance from the eccentric carrier's transmitter site and the MS's distance from the main carrier's transmitter site; see also clause 7.8.

The BS may also transmit broadcast system information to DA MSs on phase modulation carriers using the SYSINFO-DA PDU transmitted on the SCH/F, SCH-P8/HD or SCH-P8/F in any slot in frames 1 to 18; see clause 23.6.10.

Further information about the usage of broadcast messages by DA MSs is contained in clauses 23.6.7, 23.6.8, 23.6.9, 23.6.10 and 23.6.11.

## 23.6.2 Acquiring cell synchronization on a CA cell

An MS synchronizes with a CA cell by first attempting to synchronize with the synchronization training sequence contained in the synchronization burst (BSCH). On acquiring synchronization, the MS shall then decode the contents of the SYNC PDU also contained in the synchronization burst. The SYNC PDU contains the colour code, which shall be used by the MS to de-scramble the contents of all other bursts transmitted by that BS, and the system code, which indicates whether the system is a TETRA V+D system (or whether this is a Direct Mode transmission). The SYNC PDU also contains the slot, frame and multiframe number for this downlink slot giving the MS full synchronization with this BS. The SYNC PDU also contains some information about the discontinuous mode of operation of the BS for phase modulation carriers.

The MS may acquire cell synchronization on any phase modulation downlink carrier being transmitted by the BS for that CA cell. The BSCH information shall be the same for all carriers within the cell, and the slot, frame and multiframe synchronization shall be the same.

Having synchronized with a CA cell, the MS shall continue to decode subsequent SYNC PDUs transmitted by that BS but shall only use those with the correct value of the "colour code" element to prevent an MS from using the BSCH transmitted by an adjacent cell.

NOTE: There is no other co-channel interference protection on the BSCH.

The MS shall store the information received in the SYNC PDU and shall update this stored information on receiving subsequent SYNC PDUs.

### 23.6.3 Acquiring network information on a CA cell

An MS, having acquired synchronization with a CA cell by receiving and decoding the BSCH information (SYNC PDU), is able to decode all  $\pi/4$ -DQPSK downlink bursts transmitted by the BS. First of all, the MS shall search for the BNCH in order to receive and decode the SYSINFO PDU containing system information for this cell. The SYSINFO PDU contains information about the frequency of the main carrier of this CA cell, the number of common secondary control channels in operation on the main carrier, information used for power control and cell (re-)selection (parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT) and some random access parameters (see clause 21 for full description). The MAC shall decode the SYSINFO PDU and store the MAC parameters. On receiving subsequent SYSINFO PDUs, the MAC shall update the stored parameters accordingly.

Having decoded the SYNC and SYSINFO PDUs, the MS may locate the MCCH (i.e. slot 1 of the main carrier) or the relevant common SCCH. The MS has all of the information needed to communicate with the BS and may now receive downlink PDUs and transmit uplink PDUs using the procedures defined elsewhere within the MAC protocol.

### 23.6.4 Receiving SYNC and SYSINFO PDUs on D8PSK channel - CA MS

On a D8PSK channel, the BS shall transmit the BSCH (containing the SYNC PDU) and BNCH (containing the SYSINFO PDU) in frame 18 according to the mapping described in clause 9, and using  $\pi/4$ -DQPSK bursts. The SYSINFO PDU may also be transmitted in other slots in frame 18 and in frames 1 to 17, in which case the BS may use either a  $\pi/4$ -DQPSK burst or a  $\pi/8$ -D8PSK burst.

The SYNC and SYSINFO PDUs shall be received and decoded by all CA MSs using a D8PSK channel. The MS shall use the same procedures as described in clauses 23.6.1, 23.6.2 and 23.6.3 with the following exception:

- parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are specific to that D8PSK channel (see clause 23.6.6); therefore, on receipt of the SYSINFO PDU on a D8PSK channel, the MS shall not overwrite the equivalent stored parameters received on a  $\pi/4$ -DQPSK or QAM channel (or received on a concurrent D8PSK channel).

NOTE: When an MS first acquires cell synchronization and network information on a CA cell (using the procedure described in clauses 23.6.2 and 23.6.3), if the BNCH was received on a D8PSK channel then the MS's first stored values of parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT will be the values for the D8PSK channel - which may be different from the values for a conforming  $\pi/4$ -DQPSK channel. However, when the MS moves to the MCCH or the relevant common SCCH, it will receive the values for a conforming  $\pi/4$ -DQPSK channel when it receives the SYSINFO PDU on that channel and will update the stored parameters accordingly.

### 23.6.5 Receiving SYSINFO-Q PDU on QAM channel - CA MS

There is a QAM broadcast network logical channel BNCH-Q (containing the SYSINFO-Q or SYSINFO-DA PDU), which the BS may transmit on SCH-Q/D in any slot in frames 1 to 18 of a QAM channel. The SYSINFO-Q PDU is used by CA MSs, whereas the SYSINFO-DA PDU is used by DA MSs.

In the present document, there is no fixed mapping of the SYSINFO-Q PDU on a QAM channel.

NOTE 1: There is also a QAM broadcast synchronization logical channel BSCH-Q (containing the SYNC-DA PDU), which the BS may transmit on QAM channels. The SYNC-DA PDU is used by DA MSs.

The SYSINFO-Q PDU shall be received and decoded by all CA MSs using a QAM channel. A CA MS, on receiving and correctly decoding the SYSINFO-Q PDU, shall remove the MAC header and shall store the parameters contained therein. The MAC shall then pass the TM-SDU to the MLE. Upon receiving subsequent SYSINFO-Q PDUs on that channel, the MAC shall update its stored parameters before passing the MLE data contained in the TM-SDU to the LLC which shall then pass the MLE data transparently to the MLE. The appropriate MAC primitive for the MAC to pass the MLE data to the LLC is the TMB-SYSINFO-Q indication.

NOTE 2: In addition to the TM-SDU, the TMB-SYSINFO-Q indication primitive may include extended services information from the MAC PDU.

The SYSINFO-Q PDU contains information about the frequency of the main carrier of this CA cell, the number of common secondary control channels in operation on the main carrier, information used for power control and cell (re-)selection or assigned channel replacement, an encryption parameter, some random access parameters and the "extended services broadcast" element (see clause 21 for full description).

The information about the frequency of the main carrier of this CA cell, the number of common secondary control channels in operation on the main carrier, encryption and extended services transmitted within the SYSINFO-Q PDU shall be identical to the equivalent information in the SYSINFO PDU transmitted on phase modulation carriers within that cell. Therefore the MS shall update these stored parameters whenever it receives either a SYSINFO or SYSINFO-Q PDU.

However, parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are specific to that QAM channel (see clause 23.6.6). Therefore, on receipt of the SYSINFO-Q PDU, the MS shall not overwrite the equivalent stored parameters received on a  $\pi/4$ -DQPSK or D8PSK channel (or received on a concurrent QAM channel).

The BS does not send the colour code, timeslot number, frame number, multiframe number or hyperframe number to CA MSs on a QAM channel. Therefore, when a CA MS is on a QAM channel, it shall use the colour code last received in a SYNC PDU on a phase modulation channel within that cell. Also it shall derive its timeslot, frame, multiframe and hyperframe numbering from that last received in SYNC and SYSINFO PDUs on a phase modulation channel within that cell. This implies that all QAM carriers used by a CA cell shall be synchronized in time with the phase modulation carrier(s) used by that cell; see clause 7 for details of the synchronization of phase modulation carriers and QAM carriers.

NOTE 3: The carriers belonging to a BS are synchronized in time as defined in clause 7.7. However the MS may perceive a larger timing difference between an eccentric carrier and the main carrier than between a non-eccentric carrier and the main carrier; see also clause 7.8.

Also the BS does not send any information about the discontinuous mode of operation (or U-plane DTX or frame 18 extension) to CA MSs on a QAM channel; therefore, when a CA MS is on a QAM channel, it shall assume that the last information received in SYNC and SYSINFO PDUs within that cell still applies on phase modulation carriers.

## 23.6.6 Power control and cell/channel reselection parameters for CA

### 23.6.6.0 General

The power control and cell (re-)selection or assigned channel replacement parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are broadcast by the BS:

- in the SYSINFO PDU broadcast by the BS to all MSs on a  $\pi/4$ -DQPSK or D8PSK channel;
- in the SYSINFO-Q PDU broadcast by the BS to CA MSs on a QAM channel.

NOTE: If DA MSs are also present on a QAM channel, the BS may send the SYSINFO-DA and SYNC-DA PDUs to those MSs; see clause 23.6.11. Also, if DA MSs are present on a  $\pi/4$ -DQPSK or D8PSK channel, the BS may send the SYSINFO-DA PDU to those MSs; see clause 23.6.10.

Parameters MS\_TXPWR\_MAX\_CELL and ACCESS\_PARAMETER are used in the open loop power control procedure (see clause 23.4.4.2). Parameters MS\_TXPWR\_MAX\_CELL and RXLEV\_ACCESS\_MIN are used in the calculation of the path loss parameter for the current channel on the serving cell, and for adjacent cells by scanning, and for the main carrier of the serving cell by monitoring (see clause 23.7). RADIO\_DOWNLINK\_TIMEOUT is used for assessing the quality of the downlink of the current channel on the serving cell (see clause 23.7.3).

The values of parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT may vary according to the modulation mode and bandwidth of the channel and according to whether the channel is conforming, non-conforming concentric, sectored, super-sectored or eccentric (see clause 23.7 for the definition of conforming, concentric, sectored, super-sectored and eccentric channels).

### 23.6.6.1 $\pi/4$ -DQPSK channel

When an MS first acquires a CA main carrier or receives a channel allocation for a  $\pi/4$ -DQPSK channel on a CA new cell, the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT obtained when it acquired network information by receiving the SYSINFO PDU on that cell (see clause 23.6.3).

When a CA MS is sent to a new  $\pi/4$ -DQPSK channel within the cell, or when it returns to the MCCH or to a  $\pi/4$ -DQPSK common SCCH, the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT last received on a conforming  $\pi/4$ -DQPSK channel in that cell.

In either case, on receiving subsequent SYSINFO PDUs on the  $\pi/4$ -DQPSK channel, the MS-MAC shall update the MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT parameters for that channel accordingly.

### 23.6.6.2 D8PSK channel

When a CA MS is sent to a D8PSK channel, the MS-MAC shall make the following assumptions about the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT until updated by receiving SYSINFO PDUs on that channel:

- If the MS-MAC has previously received the SYSINFO PDU on a D8PSK channel in that cell, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a D8PSK channel in that cell.
- Otherwise (i.e. if the MS-MAC has not previously received the SYSINFO PDU on a D8PSK channel in that cell) the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT last received on a conforming  $\pi/4$ -DQPSK channel in that cell.

In either case, on receiving a SYSINFO PDU on the D8PSK channel, the MS-MAC shall update the MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT parameters for that channel accordingly.

### 23.6.6.3 QAM channel

When a CA MS is sent to a QAM channel with RF bandwidth B, the MS-MAC shall make the following assumptions about the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT until updated by receiving SYSINFO-Q PDUs on that channel:

- If the MS-MAC has previously received the SYSINFO-Q PDU on a QAM channel in that cell with the same bandwidth B, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a QAM channel in that cell with bandwidth B.
- Otherwise (i.e. if the MS-MAC has not previously received the SYSINFO-Q PDU on a QAM channel in that cell with the same bandwidth B):
  - a) the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT last received on a conforming  $\pi/4$ -DQPSK channel in that cell;

- b) the MS-MAC shall use a value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) + \text{CONVERSION\_FACTOR} \quad (23.8)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming  $\pi/4$ -DQPSK channel in that cell and:

- `CONVERSION_FACTOR` = -3 dB if the bandwidth B of the QAM channel is 25 kHz;
- `CONVERSION_FACTOR` = 0 dB if the bandwidth B of the QAM channel is 50 kHz;
- `CONVERSION_FACTOR` = 3 dB if the bandwidth B of the QAM channel is 100 kHz;
- `CONVERSION_FACTOR` = 5 dB if the bandwidth B of the QAM channel is 150 kHz.

In either case, on receiving a `SYSINFO-Q` PDU on the QAM channel, the MS-MAC shall update the `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` parameters for that channel accordingly.

### 23.6.7 Acquiring cell synchronization on a DA cell

An MS synchronizes with a DA cell by first attempting to find and synchronize with the QAM Frequency Correction downlink Burst (FCB). The MS shall then decode the contents of the `SYNC-DA` PDU in the logical channel `BSCH-Q`, which is contained within the FCB. The `SYNC-DA` PDU contains:

- a) the system code;
- b) information about the bandwidth of the downlink main carrier of this DA cell;
- c) information about the frequency of the downlink main carrier of this DA cell (included when the PDU is sent on a QAM carrier other than the DA main carrier);
- d) the Location Area (LA) in which this DA cell is located (included when the PDU is sent on the DA main carrier);
- e) essential information about the security and services provided by this BS;
- f) the cell selection parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` for the main carrier of this DA cell;
- g) the colour code, which shall be used by the MS to de-scramble the contents of all other logical channels transmitted by this BS;
- h) the slot, frame and multiframe number for this downlink slot, giving the MS full synchronization with the BS.

This information enables the MS to synchronize, to locate the downlink main carrier of this DA cell and to decide whether it wishes to use the cell. It also enables the MS to receive other bursts transmitted by the BS on the downlink main carrier of this DA cell.

NOTE 1: The `SYNC-DA` PDU contains essential information for the MS to decide whether it wishes to use the cell. However the `SYSINFO-DA` PDU contains some additional information about the cell, so the MS may prefer to receive the `SYSINFO-DA` PDU on a likely cell before confirming its decision.

It is optional for the BS to transmit the `SYNC-DA` PDU on carriers other than the DA main carrier. The `SYNC-DA` information shall be the same for all carriers on which it is transmitted within the cell (except see items c) and d) above); and the slot, frame and multiframe synchronization shall be the same.

The MS may acquire cell synchronization on any QAM downlink carrier for that DA cell on which the BS chooses to transmit the `SYNC-DA` PDU. However the MS needs to locate the DA main carrier in order to perform path loss measurements and to receive other bursts transmitted by the BS.

Having synchronized with a DA cell, the MS may continue to decode subsequent `SYNC-DA` PDUs transmitted by the BS. If the MS continues to decode subsequent `SYNC-DA` PDUs transmitted by the BS, it shall only use those with the correct value of the "colour code" element to prevent the MS from using the `BSCH-Q` transmitted by an adjacent cell.

NOTE 2: There is no other co-channel interference protection on the `BSCH-Q`.

If the MS continues to decode subsequent SYNC-DA PDUs transmitted by the BS, it shall update its stored information on receiving SYNC-DA PDUs.

### 23.6.8 Acquiring network information on a DA cell

An MS, having acquired synchronization with a DA cell by receiving and decoding the BSCH-Q information (SYNC-DA PDU), is able to locate the downlink main carrier of the DA cell and to decide whether it wishes to use the cell. It is also able to receive other bursts transmitted by the BS on the downlink main carrier.

If the MS wishes to use the cell, it also needs to receive and decode the SYSINFO-DA PDU. This PDU duplicates some of the information from the SYNC-DA PDU and also contains further system information for this cell. The further information includes the duplex spacing of the DA main carrier, the number of slots comprising the MCCH-Q or the number of QAM common secondary control channels in operation on the main carrier, further information used for power control and cell (re-)selection, the hyperframe number, some random access and other radio parameters and some further details about the security and services provided by this BS. (See clause 21 for full description.) The MAC shall decode the SYSINFO-DA PDU and store all the MAC parameters.

Having decoded the SYNC-DA and SYSINFO-DA PDUs, the MS may locate the MCCH-Q or the relevant QAM common SCCH. The MS has all of the information needed to communicate with the BS and may now receive other downlink PDUs and transmit uplink PDUs using the procedures defined elsewhere within the MAC protocol.

While camped on the cell, the MS shall continue to decode subsequent SYSINFO-DA PDUs transmitted by the BS. On receiving subsequent SYSINFO-DA PDUs, the MAC shall update its stored parameters accordingly.

### 23.6.9 Receiving SYNC and SYSINFO PDUs on $\pi/4$ -DQPSK or D8PSK channel - DA MS

On a  $\pi/4$ -DQPSK channel, the BS shall transmit the BSCH (containing the SYNC PDU) and BNCH (containing the SYSINFO PDU) in frame 18 according to the mapping described in clause 9, using  $\pi/4$ -DQPSK bursts. The SYSINFO PDU may also be transmitted in other slots in frame 18 and in frames 1 to 17, using a  $\pi/4$ -DQPSK burst.

Similarly, on a D8PSK channel, the BS shall transmit the BSCH (containing the SYNC PDU) and BNCH (containing the SYSINFO PDU) in frame 18 according to the mapping described in clause 9, using  $\pi/4$ -DQPSK bursts. The SYSINFO PDU may also be transmitted in other slots in frame 18 and in frames 1 to 17, in which case the BS may use either a  $\pi/4$ -DQPSK burst or a  $\pi/8$ -D8PSK burst.

The SYNC and SYSINFO PDUs shall be received and decoded by all MSs using a  $\pi/4$ -DQPSK or D8PSK channel, including DA MSs.

A DA MS shall decode all SYNC PDUs it receives but shall only use those with the correct value of the "colour code" element for its DA operation - to prevent an MS from using the BSCH transmitted by an adjacent cell.

NOTE 1: There is no other co-channel interference protection on the BSCH.

DA MSs shall use the information in the SYNC and SYSINFO PDUs that is appropriate to its operation on the current channel, for example:

- timeslot, frame, multiframe and hyperframe numbering;
- the power control and cell (re-)selection or assigned channel replacement parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT;
- the default definition for access code A;
- information about frame 18 extension;
- information about discontinuous operation and U-plane DTX;
- encryption and security parameters;
- information about whether data priority is supported; and

- information about whether extended advanced links and MAC-U-BLCK are supported.

However, a DA MS does not need to process information specific to CA operation such as information about the (if any) CA main carrier, other services provided by the (if any) associated CA cell, the Location Area LA of the (if any) associated CA cell and the subscriber classes allowed to use the (if any) associated CA cell.

NOTE 2: As indicated above, a DA MS does not need to process the information about the subscriber classes allowed to use the (if any) associated CA cell, as included in the SYSINFO PDU at the MLE level. However, if a DA MS on a  $\pi/4$ -DQPSK or D8PSK channel receives an ACCESS-DEFINE PDU containing the "subscriber class bit map" element, it uses that element in the usual way when following the random access procedures on that channel (as defined in clause 23.5.1.4).

The MS shall store the appropriate information received in the SYNC and SYSINFO PDUs and shall update this stored information on receiving subsequent SYNC and SYSINFO PDUs on this channel.

Parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are specific to the current  $\pi/4$ -DQPSK or D8PSK channel (see clause 23.6.11). Therefore, on receipt of the SYSINFO PDU on a  $\pi/4$ -DQPSK channel, the MS shall not overwrite the equivalent stored parameters received on a D8PSK or QAM channel (or received on a concurrent  $\pi/4$ -DQPSK channel). Similarly, on receipt of the SYSINFO PDU on a D8PSK channel, the MS shall not overwrite the equivalent stored parameters received on a  $\pi/4$ -DQPSK or QAM channel (or received on a concurrent D8PSK channel).

### 23.6.10 Receiving SYSINFO-DA PDU on $\pi/4$ -DQPSK or D8PSK channel - DA MS

The BS may transmit the SYSINFO-DA PDU on a  $\pi/4$ -DQPSK or D8PSK channel. On a  $\pi/4$ -DQPSK channel, it uses a  $\pi/4$ -DQPSK burst (logical channel SCH/F); or, on a D8PSK channel, it uses either a  $\pi/4$ -DQPSK burst (logical channel SCH/F) or a  $\pi/8$ -D8PSK burst (logical channel SCH-P8/HD or SCH-P8/F). For example, the BS may choose to transmit the SYSINFO-DA PDU on a  $\pi/4$ -DQPSK or D8PSK channel if there are DA MSs on the channel and the BS needs to move the DA main carrier or change its configuration.

NOTE: If an  $\pi/4$ -DQPSK or D8PSK channel is shared by MSs from different DA cells, the BS should not send the SYSINFO-DA PDU on that  $\pi/4$ -DQPSK or D8PSK channel.

The power control and cell (re-)selection or assigned channel replacement parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are not present in the SYSINFO-DA PDU if the PDU is sent on a  $\pi/4$ -DQPSK or D8PSK channel. Therefore, if a DA MS on a  $\pi/4$ -DQPSK or D8PSK channel receives a SYSINFO-DA PDU on that channel, it shall not update its power control and cell (re-)selection or assigned channel replacement parameters.

Similarly, the random access parameters (default definition for access code A) are not present in the SYSINFO-DA PDU if the PDU is sent on a  $\pi/4$ -DQPSK or D8PSK channel. Therefore, if a DA MS on a  $\pi/4$ -DQPSK or D8PSK channel receives a SYSINFO-DA PDU on that channel, it shall not update its random access parameters.

The MS shall store the other information received in the SYSINFO-DA PDU and shall update this stored information on receiving subsequent SYSINFO-DA PDUs on this channel.

### 23.6.11 Power control and cell/channel reselection parameters for DA

#### 23.6.11.0 General

The power control and cell (re-)selection or assigned channel replacement parameters MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are broadcast by the BS:

- in the SYSINFO-DA PDU broadcast by the BS to DA MSs on a QAM channel;
- in the SYNC-DA PDU broadcast by the BS to DA MSs on a QAM channel (contains MS\_TXPWR\_MAX\_CELL and RXLEV\_ACCESS\_MIN for the DA main carrier);
- in the SYSINFO PDU broadcast by the BS on a  $\pi/4$ -DQPSK or D8PSK channel.

NOTE 1: The power control and cell (re-)selection or assigned channel replacement parameters are not present in the SYSINFO-DA PDU if the PDU is sent on a  $\pi/4$ -DQPSK or D8PSK channel.

NOTE 2: If there are also CA MSs on a QAM channel, the BS may send the SYSINFO-Q PDU to those MSs.

Parameters `MS_TXPWR_MAX_CELL` and `ACCESS_PARAMETER` are used in the open loop power control procedure (see clause 23.4.4.2). Parameters `MS_TXPWR_MAX_CELL` and `RXLEV_ACCESS_MIN` are used in the calculation of the path loss parameter for the current channel on the serving cell, and for adjacent cells by scanning, and for the main carrier of the serving cell by monitoring (see clause 23.7). `RADIO_DOWNLINK_TIMEOUT` is used for assessing the quality of the downlink of the current channel on the serving cell (see clause 23.7.3).

The values of parameters `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` may vary according to the modulation mode and bandwidth of the channel and according to whether the channel is conforming, non-conforming concentric, sectored, super-sectored or eccentric (see clause 23.7 for the definition of conforming, concentric, sectored, super-sectored and eccentric channels).

### 23.6.11.1 QAM channel

When an MS first acquires a DA main carrier or receives a channel allocation for a QAM channel on a DA new cell, the MS-MAC shall use the values of `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` obtained when it acquired network information by receiving the SYSINFO-DA PDU on that cell (see clause 23.6.8).

When a DA MS returns to the MCCH-Q or to a QAM common SCCH, the MS-MAC shall use the values of `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` last received on a conforming QAM channel in that cell with the same bandwidth as the DA main carrier (i.e. either the MCCH-Q or a QAM common SCCH or a conforming QAM assigned channel with the same bandwidth as the DA main carrier).

When a DA MS is sent to a new QAM channel, with RF bandwidth  $B$ , the MS-MAC shall make the following assumptions about the values of `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` until updated by receiving SYSINFO-DA PDUs on that channel:

- If the MS-MAC has previously received the SYSINFO-DA PDU on a QAM channel in that cell with the same bandwidth  $B$ , it shall assume that the values of `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` are equal to those last received on a QAM channel in that cell with bandwidth  $B$ .
- Otherwise (i.e. if the MS-MAC has not previously received the SYSINFO-DA PDU on a QAM channel in that cell with the same bandwidth  $B$ ):
  - a) the MS-MAC shall use the values of `MS_TXPWR_MAX_CELL`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier;
  - b) the MS-MAC shall use a value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) + 10 \log_{10} ( B / B_m ) \quad (23.9)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier.

In all cases, on receiving subsequent SYSINFO-DA PDUs on the QAM channel, the MS-MAC shall update the `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` parameters for that channel accordingly. Also, when on the QAM common control channel, the MS-MAC may update the `MS_TXPWR_MAX_CELL` and `RXLEV_ACCESS_MIN` parameters when it receives SYNC-DA PDUs.

### 23.6.11.2 $\pi/4$ -DQPSK channel

When a DA MS is sent to a  $\pi/4$ -DQPSK channel, the MS-MAC shall make the following assumptions about the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT until updated by receiving SYSINFO PDUs on that channel:

- If the MS-MAC has previously received the SYSINFO PDU on a  $\pi/4$ -DQPSK channel in that cell, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a  $\pi/4$ -DQPSK channel in that cell.
- Otherwise, if the MS-MAC has previously received the SYSINFO PDU on a D8PSK channel in that cell, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a D8PSK channel in that cell.
- Otherwise (i.e. if the MS-MAC has not previously received the SYSINFO PDU in that cell):
  - a) the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier;
  - b) the MS-MAC shall use a value of RXLEV\_ACCESS\_MIN equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) - \text{CONVERSION\_FACTOR} \quad (23.10)$$

where RXLEV\_ACCESS\_MIN(main) is the value of RXLEV\_ACCESS\_MIN last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier and:

- CONVERSION\_FACTOR = -3 dB if the bandwidth  $B_m$  of the QAM channel was 25 kHz;
- CONVERSION\_FACTOR = 0 dB if the bandwidth  $B_m$  of the QAM channel was 50 kHz;
- CONVERSION\_FACTOR = 3 dB if the bandwidth  $B_m$  of the QAM channel was 100 kHz;
- CONVERSION\_FACTOR = 5 dB if the bandwidth  $B_m$  of the QAM channel was 150 kHz.

In all cases, on receiving a SYSINFO PDU on the  $\pi/4$ -DQPSK channel, the MS-MAC shall update the MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT parameters for that channel accordingly.

NOTE: This clause applies when an MS that is camped on a DA cell is sent to a  $\pi/4$ -DQPSK channel within the cell. It also applies during type 1 announced cell reselection if the MS receives a channel allocation for a  $\pi/4$ -DQPSK channel on a DA new cell (so the MS-MAC uses or derives the values as described above from the parameters received on the DA new cell).

### 23.6.11.3 D8PSK channel

When a DA MS is sent to a D8PSK channel, the MS-MAC shall make the following assumptions about the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT until updated by receiving SYSINFO PDUs on that channel:

- If the MS-MAC has previously received the SYSINFO PDU on a D8PSK channel in that cell, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a D8PSK channel in that cell.
- Otherwise, if the MS-MAC has previously received the SYSINFO PDU on a  $\pi/4$ -DQPSK channel in that cell, it shall assume that the values of MS\_TXPWR\_MAX\_CELL, RXLEV\_ACCESS\_MIN, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT are equal to those last received on a  $\pi/4$ -DQPSK channel in that cell.
- Otherwise (i.e. if the MS-MAC has not previously received the SYSINFO PDU in that cell):
  - a) the MS-MAC shall use the values of MS\_TXPWR\_MAX\_CELL, ACCESS\_PARAMETER and RADIO\_DOWNLINK\_TIMEOUT last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier;

- b) the MS-MAC shall use a value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) - \text{CONVERSION\_FACTOR} \quad (23.11)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming QAM channel in that cell with the same bandwidth  $B_m$  as the DA main carrier and:

- `CONVERSION_FACTOR` = -3 dB if the bandwidth  $B_m$  of the QAM channel was 25 kHz;
- `CONVERSION_FACTOR` = 0 dB if the bandwidth  $B_m$  of the QAM channel was 50 kHz;
- `CONVERSION_FACTOR` = 3 dB if the bandwidth  $B_m$  of the QAM channel was 100 kHz;
- `CONVERSION_FACTOR` = 5 dB if the bandwidth  $B_m$  of the QAM channel was 150 kHz.

In all cases, on receiving a `SYSINFO` PDU on the D8PSK channel, the MS-MAC shall update the `MS_TXPWR_MAX_CELL`, `RXLEV_ACCESS_MIN`, `ACCESS_PARAMETER` and `RADIO_DOWNLINK_TIMEOUT` parameters for that channel accordingly.

## 23.7 Layer management communication (TMC-SAP)

### 23.7.0 General

Clauses 23.7.1 to 23.7.5 describe procedures that the MAC performs as a service to the MLE for:

- estimation of the radio path loss on the current channel(s) on the serving cell;
- measurements of the quality of the link on the current channel(s) on the serving cell;
- if the MS is not currently receiving a conforming channel, and the current channel is a non-conforming concentric or sectored channel: assessment of the path loss on the main carrier of the serving cell (based on the measurements made on the current channel);
- on request of the MLE:
  - a) assessment of the path loss for channel classes on the serving cell based on the measurements made on the current channel;
  - b) neighbour cell monitoring i.e. monitoring of the main carrier on adjacent cells;
  - c) irregular channel monitoring i.e. monitoring of irregular carriers on the serving cell or on adjacent cells;
  - d) scanning of the main carrier on adjacent cells;
  - e) reception of the `SYSINFO-DA` PDU on the main carrier of a DA adjacent cell;
  - f) main carrier monitoring i.e. monitoring of the main carrier on the serving cell.

In cases b) and d), the MLE may also request assessment of the path loss for channel classes on the adjacent cell (based on the measurements made on the monitored or scanned main carrier on the adjacent cell). In case f), the MLE may also request assessment of the path loss for channel classes on the serving cell (based on the measurements made on the main carrier).

Then clause 23.7.6 defines procedures for energy economy mode, clause 23.7.7 defines procedures for selection of dual watch mode with energy economy group, and clause 23.7.8 defines procedures for part-time reception on a multi-slot `MCCH-Q`.

The following points may be noted (see clause 18):

- A "concentric channel" has essentially the same azimuthal radiation pattern as the main carrier and is radiated from the same site as the main carrier. It may have a larger or smaller range and coverage area than the main carrier (i.e. it may be a non-conforming channel); and it may use a different modulation mode, RF bandwidth and RF power from the main carrier. Where the BS offers multiple concentric channels with different RF characteristics, a concentric channel with a higher RF bandwidth will generally have a shorter range.

- A "channel class" is defined as a set of values indicating the general RF characteristics of a concentric channel or fully super-sectored channel. The MS predicts the performance of channel(s) corresponding to a channel class from measurements made on another carrier on that cell (i.e. the current channel or the main carrier on the serving cell, or the main carrier on an adjacent cell), together with the characteristics of that channel class. A cell may offer more than one channel or carrier belonging to the same channel class.
- A "conforming channel" is a special case of a concentric channel. It has essentially the same azimuthal radiation pattern as the main carrier, is radiated from the same site as the main carrier and has essentially the same range (as measured by the C1 path loss parameter) as the main carrier. A channel that is not a conforming channel is called a non-conforming channel.
- A "sectored channel" has an azimuthal extent that is smaller than, and contained entirely within, the azimuthal extent of the main carrier, and is radiated from the same site as the main carrier. It is a non-conforming channel and is not a concentric channel. The MS cannot predict the performance of a sectored channel by measurements made on any other channel; it discovers which sectored channels it can use by monitoring each sectored carrier.
- A "super-sectored channel" has an azimuthal extent that exceeds the azimuthal extent of the main carrier in at least one azimuthal direction, and is radiated from the same site as the main carrier; it is a non-conforming channel and is not a concentric or sectored channel. A super-sectored channel may be either a semi-super-sectored channel or a fully super-sectored channel:
  - A "semi-super-sectored channel" is radiated from the same site as the main carrier, and has an azimuthal extent that exceeds the azimuthal extent of the main carrier in one azimuthal direction and is less than the azimuthal extent of the main carrier in the other azimuthal direction. Since the azimuthal extent of a semi-super-sectored channel is less than the azimuthal extent of the main carrier in one azimuthal direction, the MS cannot predict the performance of a semi-super-sectored channel by measurements made on any other channel; it discovers which semi-super-sectored channels it can use by monitoring each semi-super-sectored carrier.
  - A "fully super-sectored channel" is radiated from the same site as the main carrier, and has an azimuthal extent that is greater than, and entirely contains, the azimuthal extent of the main carrier. The BS may choose whether to broadcast information about fully super-sectored channels individually or as a channel class. (Broadcast is not needed if the channel fully covers the area covered by the main carrier i.e. if the radial range of the channel is the same as, or larger than, the radial range of the main carrier; see note 2.)
- An "eccentric channel" is a channel that is not radiated from the same site as the main carrier; it is a non-conforming channel and is not a concentric, sectored or super-sectored channel. The MS cannot predict the performance of an eccentric channel by measurements made on any other channel; it discovers which eccentric channels it can use by monitoring each eccentric carrier (if the BS broadcasts information about the channel, for example, if the channel does not fully cover the area covered by the main carrier). The present document supports up to a maximum separation of 4 km between the eccentric channel's transmitter site and the main carrier's transmitter site; see clauses 7.7 and 7.8.

NOTE 1: The present document does not support use of carriers for which there is a greater separation than 4 km between the carrier's transmitter site and the main carrier's transmitter site.

- An "irregular channel" is a non-conforming channel that needs to be monitored by the MS in order for the MS to discover whether the channel would be usable as an assigned channel. Sectored channels and semi-super-sectored channels are irregular channels. An eccentric channel is an irregular channel (if it does not fully cover the area covered by the main carrier). The BS may broadcast information about a fully super-sectored channel as either a channel class or an irregular channel (if broadcast is needed, for example, if the channel does not fully cover the area covered by the main carrier i.e. if the radial range of the channel is less than the radial range of the main carrier).

NOTE 2: The BS does not need to broadcast information about conforming channels or those non-conforming channels that fully cover the area covered by the main carrier, since the MS does not normally need to assess or monitor these channels or inform the BS that these channels would be usable as an assigned channel. Nevertheless, the BS may choose to broadcast information about channels that fully cover the area covered by the main carrier; for example, in some cases, this may aid MSs that are sending or receiving real-time class data. (An MS that is sending or receiving real-time class data might prefer a channel that is more reliable than conforming when it is near the edge of the service area of the cell.)

- If the MS is not receiving a conforming channel, and the current channel is a non-conforming concentric or sectored channel, the MAC estimates the performance of the main carrier on the serving cell from measurements made on the current channel. Additionally the MLE may request that the MAC performs main carrier monitoring; this may apply particularly if the MS is receiving only sectored channel(s), but is also permitted when the MS is receiving a non-conforming concentric channel (see clause 18).

If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot estimate the performance of the main carrier on the serving cell from measurements made on that assigned channel. Therefore, when the MS is not receiving a concentric or sectored channel, the MLE needs to request that the MAC performs main carrier monitoring.

- When assessment of channel classes on the serving cell is required:
  - if the MS is on a concentric or sectored channel, the MLE may request assessment of the path loss for those channel classes based on the measurements made on the current channel; this process is referred to as serving cell channel class assessment;
  - alternatively (or additionally), the MLE may request main carrier monitoring with assessment of the path loss for those channel classes based on the measurements made on the main carrier; this process is referred to as main carrier monitoring with assessment of channel classes.

Main carrier monitoring with assessment of channel classes may apply particularly if the MS is receiving only sectored channel(s), but is not precluded when the MS is receiving a concentric channel (see clause 18).

If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform assessment of channel classes based on measurements made on that assigned channel. Therefore main carrier monitoring with assessment of channel classes is needed if the MS is receiving only super-sectored channel(s) and/or eccentric channel(s) (or if the MS did not understand the conforming channel status).

- When assessment of channel classes on an adjacent cell is required, the MLE requests neighbour cell monitoring or scanning of the adjacent cell main carrier with assessment of the path loss for those channel classes (based on the measurements made on the monitored or scanned adjacent cell main carrier); this process is referred to as neighbour cell channel class assessment.

The main carrier is a phase modulation carrier for a Conventional Access cell or a QAM carrier for a Direct Access cell. Where there are differences in the procedures, these are indicated in the following clauses.

## 23.7.1 Path loss calculation

### 23.7.1.0 General

The MAC layer makes signal strength measurements both autonomously on the current channel(s) on the serving cell and, under the control of the MLE layer, on selected neighbouring cells and on selected other carriers on the serving cell. The signal strength measurements shall be passed to the MLE as an approximation of radio path loss using the path loss parameters, C1 and C2, which are defined in clauses 23.7.1.1 and 23.7.1.2.

When the MS is not receiving a conforming channel, and the current channel is a non-conforming concentric or sectored channel, the MAC layer autonomously estimates the path loss C3 on the main carrier of the serving cell (based on the measurements made on the current channel) and passes it to the MLE.

Also, under control of the MLE layer, the MAC layer estimates the path loss as follows and passes it to the MLE:

- it estimates the path loss C4 for selected channel classes on the serving cell (based on the measurements made on the current channel);
- it estimates the path loss C5 for selected channel classes on the serving cell (based on measurements made on the main carrier of the serving cell);
- it estimates the path loss C5 for selected channel classes on adjacent cells (based on measurements made on the main carrier of the adjacent cell).

The path loss parameters C3, C4 and C5 are defined in clauses 23.7.1.3, 23.7.1.4 and 23.7.1.5.

The process of estimating the path loss of the serving cell main carrier or of a channel class (on the serving cell or an adjacent cell), based on measurements made on another channel or carrier radiated from the same site, is referred to as "assessment".

NOTE: If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform assessment of the serving cell main carrier or assessment of channel classes based on measurements made on that assigned channel.

### 23.7.1.1 Path loss parameter C1

The MS shall calculate the path loss parameter, C1, according to the following formula:

$$C1 = \text{RSSI} - \text{RXLEV\_ACCESS\_MIN} - \text{Max} ( 0, \text{MS\_TXPWR\_MAX\_CELL} - P_{\text{MSMAX}} ) \quad (23.12)$$

where:

- RSSI = averaged received signal level at MS or equivalent signal quality measurement;
- RXLEV\_ACCESS\_MIN = the sum of the minimum power level at which the BS wishes to receive MSs and the link imbalance for an MS transmitting at MS\_TXPWR\_MAX\_CELL on this channel;
- MS\_TXPWR\_MAX\_CELL = maximum MS transmit power permissible on this channel;
- P<sub>MSMAX</sub> = maximum transmit power of the MS for the modulation mode on this channel.

C1 is expressed in dB and all the other parameters in dBm.

C1 is calculated for the current channel(s) on the serving cell, and for adjacent cell main carriers by scanning. RSSI, therefore, is defined in the relevant clauses for serving cell measurement (see clause 23.7.3) and scanning (see clause 23.7.5).

The cell selection or assigned channel replacement parameters, RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL, shall be transmitted on CA cells using the Broadcast Network Channel (BNCH) containing the SYSINFO PDU. They shall be decoded for C1 calculation by MSs that are scanning CA cells. They shall also be decoded by CA MSs for C1 calculation on the serving cell. CA MSs on a QAM channel shall use the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL in the QAM Broadcast Network Channel (BNCH-Q) containing the SYSINFO-Q PDU for C1 calculation on that channel.

The values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL for the DA main carrier shall be transmitted on all DA cells using the QAM Broadcast System Channel (BSCH-Q) containing the SYNC-DA PDU, and shall be decoded for C1 calculation by MSs that are scanning DA cells.

The cell selection or assigned channel replacement parameters, RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL, shall be transmitted on DA cells using the QAM Broadcast Network Channel (BNCH-Q) containing the SYSINFO-DA PDU, and shall be decoded by DA MSs for C1 calculation on the serving cell. DA MSs on a  $\pi/4$ -DQPSK or D8PSK channel shall use the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL in the BNCH (SYSINFO PDU) for C1 calculation on that channel.

After synchronization has been acquired, the serving cell measurement procedure requires that C1 shall be calculated using the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL transmitted on the current channel. The values of parameters RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL may vary according to the modulation mode and bandwidth of the channel (and according to whether the channel is conforming, non-conforming concentric, sectored, super-sectored or eccentric):

- when an MS first acquires a CA main carrier or receives a channel allocation for a  $\pi/4$ -DQPSK channel on a CA new cell, or when a CA MS is sent to a new  $\pi/4$ -DQPSK channel within the cell or returns to the MCCH or to a  $\pi/4$ -DQPSK common SCCH, it shall make the assumptions specified in clause 23.6.6.1 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;
- when a CA MS is sent to a D8PSK channel, it shall make the assumptions specified in clause 23.6.6.2 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;

- when a CA MS is sent to a QAM channel, it shall make the assumptions specified in clause 23.6.6.3 about the values of these parameters until updated by receiving SYSINFO-Q PDUs on that channel;
- when an MS first acquires a DA main carrier or receives a channel allocation for a QAM channel on a DA new cell, or when a DA MS is sent to a new QAM channel within the cell or returns to the MCCH-Q or to a QAM common SCCH, it shall make the assumptions specified in clause 23.6.11.1 about the values of these parameters until updated by receiving SYSINFO-DA (or SYNC-DA) PDUs on that channel;
- when a DA MS is sent to a  $\pi/4$ -DQPSK channel, it shall make the assumptions specified in clause 23.6.11.2 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel;
- when a DA MS is sent to a D8PSK channel, it shall make the assumptions specified in clause 23.6.11.3 about the values of these parameters until updated by receiving SYSINFO PDUs on that channel.

The scanning procedures also require a calculation of C1 on adjacent cells; in this case, the MS shall be synchronized to the adjacent cell and shall use the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL transmitted on the main carrier of that adjacent cell in the above C1 calculation. If the adjacent cell is a CA cell, the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL are contained in the SYSINFO PDU transmitted on the main carrier of that adjacent cell. If the adjacent cell is a DA cell, the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL are contained in SYNC-DA and SYSINFO-DA PDUs transmitted on the main carrier of that adjacent cell.

### 23.7.1.2 Path loss parameter C2

The MS shall calculate the path loss parameter, C2, according to the following formula:

$$C2(n) = \text{RSSI}(n) - \text{RXLEV\_ACCESS\_MIN\_MCELL}(n) - \text{Max} ( 0, \text{MS\_TXPWR\_MAX\_MCELL}(n) - P_{\text{MSMAX}}(n) ) \quad (23.13)$$

where:

- RSSI(n) = averaged received signal level at MS or equivalent signal quality measurement on the monitored carrier;
- RXLEV\_ACCESS\_MIN\_MCELL(n) = the sum of the minimum power level at which the BS wishes to receive MSs and the link imbalance for an MS transmitting at MS\_TXPWR\_MAX\_MCELL(n) on the monitored carrier;
- MS\_TXPWR\_MAX\_MCELL(n) = maximum MS transmit power allowed on the monitored carrier;
- $P_{\text{MSMAX}}(n)$  = maximum transmit power of the MS for the modulation mode on the monitored carrier.

C2 is expressed in dB and all the other parameters in dBm. (n) indicates the n<sup>th</sup> monitored carrier.

C2 is calculated for the main carrier on adjacent cells, by monitoring. C2 is also calculated for irregular carriers on both the serving cell and adjacent cells, by monitoring. C2 may be calculated for the main carrier on the serving cell, by monitoring. RSSI, therefore, is defined in the relevant clause for monitoring (see clause 23.7.4).

The cell selection parameters, RXLEV\_ACCESS\_MIN\_MCELL(n) and MS\_TXPWR\_MAX\_MCELL(n), for the main carrier on adjacent cells may be transmitted in the serving cell using an MLE broadcast message on the relevant common control channel (main and/or secondary). The MLE broadcast message for transmitting the cell selection parameters for the main carrier on CA adjacent cells is the D-NWRK-BROADCAST PDU (or D-NWRK-BROADCAST-DA PDU, see note). The MLE broadcast message for transmitting the cell selection parameters (and RF bandwidth B) for the main carrier on DA adjacent cells is the D-NWRK-BROADCAST-DA PDU.

**NOTE:** MSs generally obtain information about the main carrier on CA adjacent cells from the D-NWRK-BROADCAST PDU. However DA MSs may obtain information about the main carrier of the (if any) local CA cell from the D-NWRK-BROADCAST-DA PDU. (DA MSs obtain information about the channel classes and/or irregular channels on the local CA cell from the D-NWRK-BROADCAST-EXTENSION PDU.)

In the case where these parameters are not known by the serving cell or where the MS has not received them on the serving cell:

- For a CA MS monitoring a CA adjacent cell, the MS shall use the cell selection parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell as default values. These are broadcast on the serving cell BNCH in the SYSINFO PDU.
- For a DA MS monitoring a DA adjacent cell:
  - If the MS has received the SYSINFO-DA PDU on a QAM channel on the serving cell with the same bandwidth  $B$  as the main carrier of the adjacent cell, it shall use as default values the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a QAM channel on the serving cell with bandwidth  $B$ .
  - Otherwise (i.e. if the MS has not received the SYSINFO-DA PDU on a QAM channel on the serving cell with the same bandwidth  $B$  as the main carrier of the adjacent cell):
    - a) the MS shall use as a default value the parameter `MS_TXPWR_MAX_CELL` last received on a conforming QAM channel on the serving cell with the same bandwidth  $B_m$  as the main carrier of the serving cell;
    - b) the MS shall use a default value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) + 10 \log_{10} ( B / B_m ) \quad (23.14)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming QAM channel on the serving cell with the same bandwidth  $B_m$  as the main carrier of the serving cell.

- For a CA MS monitoring a DA adjacent cell:
  - If the MS has received the SYSINFO-Q PDU on a QAM channel on the serving cell with the same bandwidth  $B$  as the main carrier of the DA adjacent cell, it shall use as default values the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a QAM channel on the serving cell with bandwidth  $B$ .
  - Otherwise (i.e. if the MS has not received the SYSINFO-Q PDU on a QAM channel on the serving cell with the same bandwidth  $B$  as the main carrier of the DA adjacent cell):
    - a) the MS shall use as a default value the parameter `MS_TXPWR_MAX_CELL` last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell;
    - b) the MS shall use a default value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) + \text{CONVERSION\_FACTOR} \quad (23.15)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell and:

- `CONVERSION_FACTOR` = -3 dB if the bandwidth  $B$  of the DA main carrier is 25 kHz;
  - `CONVERSION_FACTOR` = 0 dB if the bandwidth  $B$  of the DA main carrier is 50 kHz;
  - `CONVERSION_FACTOR` = 3 dB if the bandwidth  $B$  of the DA main carrier is 100 kHz;
  - `CONVERSION_FACTOR` = 5 dB if the bandwidth  $B$  of the DA main carrier is 150 kHz.
- For a DA MS monitoring a CA adjacent cell:
    - If the MS has received the SYSINFO PDU on a  $\pi/4$ -DQPSK channel on the serving cell, it shall use as default values the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a  $\pi/4$ -DQPSK channel on the serving cell.
    - Otherwise, if the MS has received the SYSINFO PDU on a D8PSK channel on the serving cell, it shall use as default values the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a D8PSK channel on the serving cell.

- Otherwise (i.e. if the MS has not received the SYSINFO PDU on the serving cell):
  - a) the MS shall use as a default value the parameter `MS_TXPWR_MAX_CELL` last received on a conforming QAM channel on the serving cell with the same bandwidth  $B_m$  as the main carrier of the serving cell;
  - b) the MS shall use a default value of `RXLEV_ACCESS_MIN` equal to:

$$\text{RXLEV\_ACCESS\_MIN}(\text{main}) - \text{CONVERSION\_FACTOR} \quad (23.16)$$

where `RXLEV_ACCESS_MIN(main)` is the value of `RXLEV_ACCESS_MIN` last received on a conforming QAM channel on the serving cell with the same bandwidth  $B_m$  as the main carrier of the serving cell and:

- `CONVERSION_FACTOR` = -3 dB if the bandwidth  $B_m$  of the DA main carrier is 25 kHz;
- `CONVERSION_FACTOR` = 0 dB if the bandwidth  $B_m$  of the DA main carrier is 50 kHz;
- `CONVERSION_FACTOR` = 3 dB if the bandwidth  $B_m$  of the DA main carrier is 100 kHz;
- `CONVERSION_FACTOR` = 5 dB if the bandwidth  $B_m$  of the DA main carrier is 150 kHz.

The parameters `RXLEV_ACCESS_MIN_MCELL(n)` and `MS_TXPWR_MAX_MCELL(n)`, and the modulation mode and RF bandwidth, for irregular carriers on the serving cell or adjacent cells shall be transmitted in the serving cell using an MLE broadcast message (D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

When performing monitoring of the main carrier of the serving cell:

- a CA MS shall use the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell for the C2 calculation; these parameters are broadcast on the serving cell BNCH in the SYSINFO PDU;
- a DA MS shall use the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a conforming QAM channel on the serving cell with the same bandwidth as the main carrier for the C2 calculation; these parameters are broadcast on the serving cell BNCH-Q in the SYSINFO-DA PDU.

### 23.7.1.3 Path loss parameter C3

The MAC layer autonomously calculates the path loss parameter C1 for the current channel (see clause 23.7.1.1) and passes it to the MLE. Also, when the MS is not receiving a conforming channel, and the current channel is a non-conforming concentric or sectorized channel, the MAC layer autonomously estimates the path loss C3 on the main carrier of the serving cell, based on the measurements made on the current channel, and passes it to the MLE. This process is referred to as assessment of the main carrier.

NOTE 1: The main carrier is a phase modulation carrier for CA or a QAM carrier for DA.

NOTE 2: Additionally, if the MLE prefers the MAC to make direct measurements of the path loss on the main carrier, the MLE may request main carrier monitoring on the serving cell.

NOTE 3: If the MS is on a super-sectorized or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform assessment of the main carrier based on the measurements made on that assigned channel. Therefore, if the MS is currently receiving only super-sectorized and/or eccentric channel(s) and/or channel(s) for which it does not understand the conforming channel status, it needs to perform main carrier monitoring on the serving cell (path loss parameter C2) instead of performing assessment of the main carrier (path loss parameter C3). Thus, when the MS is not currently receiving a concentric or sectorized channel, the MLE requests that the MAC performs main carrier monitoring, by including the main carrier of the serving cell in the TMC-MONITOR-LIST request primitive (see clause 18).

The MS shall calculate the path loss parameter, C3, according to the following formula:

$$C3 = \text{RSSI} - \text{RXLEV\_ACCESS\_MIN}(\text{main}) - \text{Max} ( 0, \text{MS\_TXPWR\_MAX\_CELL}(\text{main}) - P_{\text{MSMAX}}(\text{main}) ) - \text{BS\_TXPWR\_RATIO\_CHANNEL} \quad (23.17)$$

where:

- RSSI = averaged received signal level at MS or equivalent signal quality measurement on the current channel;
- RXLEV\_ACCESS\_MIN(main) = the sum of the minimum power level at which the BS wishes to receive MSs and the link imbalance for an MS transmitting at MS\_TXPWR\_MAX\_CELL(main) on the common control channel;
- MS\_TXPWR\_MAX\_CELL(main) = maximum MS transmit power allowed on the common control channel;
- P<sub>MSMAX</sub>(main) = maximum transmit power of the MS:
  - for  $\pi/4$ -DQPSK modulation for a CA MS; or
  - for QAM modulation for a DA MS;
- BS\_TXPWR\_RATIO\_CHANNEL is the BS transmit power (ERP) relative to the main carrier for the current channel.

C3 and BS\_TXPWR\_RATIO\_CHANNEL are expressed in dB and all the other parameters in dBm.

C3 is calculated when the MS is on a non-conforming concentric or sectorized channel and is performing serving cell measurements. RSSI, therefore, is defined in the relevant clause for serving cell measurement (see clause 23.7.3).

In most cases, the MS received the value of BS\_TXPWR\_RATIO\_CHANNEL in the channel allocation that sent the MS to the current channel. However, if element "conditional element A" was included in the channel allocation that sent the MS to the current channel, a DA MS calculates the value of BS\_TXPWR\_RATIO\_CHANNEL as described in clause 23.5.4.3.9.

For CA, the parameters RXLEV\_ACCESS\_MIN(main) and MS\_TXPWR\_MAX\_CELL(main) shall be the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL last received in the SYSINFO PDU on a conforming  $\pi/4$ -DQPSK channel in this cell.

For DA, the parameters RXLEV\_ACCESS\_MIN(main) and MS\_TXPWR\_MAX\_CELL(main) shall be the values of RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL last received in the SYSINFO-DA PDU on a conforming QAM channel in this cell with the same bandwidth as the main carrier or (optionally) in the SYNC-DA PDU.

### 23.7.1.4 Path loss parameter C4

Under control of the MLE layer, the MAC estimates the values of the path loss C4 for selected channel classes on the serving cell, based on the measurements made on the current channel (together with the characteristics of the channel classes to be assessed), and passes the values of C4 to the MLE. This process is referred to as serving cell channel class assessment. Serving cell channel class assessment is applicable only when the current channel is a concentric or sectorized channel.

NOTE 1: Alternatively (or additionally), when assessment of channel classes on the serving cell is required, the MLE may request main carrier monitoring with assessment of channel classes (see clause 23.7.1.5).

NOTE 2: If the MS is on a super-sectorized or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform serving cell channel class assessment based on the measurements made on that assigned channel. Therefore, if the MS is currently receiving only super-sectorized and/or eccentric channel(s) and/or channel(s) for which it does not understand the conforming channel status, and it wishes to perform assessment of channel classes, it needs to perform main carrier monitoring with assessment of channel classes (see clause 23.7.1.5) instead of performing serving cell channel class assessment.

The MS shall calculate the path loss parameter, C4, according to the following formula:

$$C4(m) = \text{RSSI} - \text{RXLEV\_ACCESS\_MIN\_MCELL}(m) - \text{Max} ( 0, \text{MS\_TXPWR\_MAX\_MCELL}(m) - P_{\text{MSMAX}}(m) ) - ( \text{BS\_TXPWR\_RATIO\_CHANNEL} - \text{BS\_TXPWR\_RATIO\_CHANNEL}(m) ) \quad (23.18)$$

where:

- RSSI = averaged received signal level at MS or equivalent signal quality measurement on the current channel;
- RXLEV\_ACCESS\_MIN\_MCELL(m) = the sum of the minimum power level at which the BS wishes to receive MSs and the link imbalance for an MS transmitting at MS\_TXPWR\_MAX\_MCELL(m) for the assessed channel class;
- MS\_TXPWR\_MAX\_MCELL(m) = maximum MS transmit power allowed for the assessed channel class;
- P<sub>MSMAX</sub>(m) = maximum transmit power of the MS for the modulation mode of the assessed channel class;
- BS\_TXPWR\_RATIO\_CHANNEL is the BS transmit power (ERP) relative to the main carrier for the current channel;
- BS\_TXPWR\_RATIO\_CHANNEL(m) is the BS transmit power (ERP) relative to the main carrier for the assessed channel class.

C4, BS\_TXPWR\_RATIO\_CHANNEL and BS\_TXPWR\_RATIO\_CHANNEL(m) are expressed in dB and all the other parameters in dBm. (m) indicates the m<sup>th</sup> assessed channel class.

C4 is calculated for the appropriate channel classes when the MS is performing serving cell measurements. RSSI, therefore, is defined in the relevant clause for serving cell measurement (see clause 23.7.3).

If the channel allocation that sent the MS to the current channel was an augmented channel allocation:

- in most cases, the MS received the value of BS\_TXPWR\_RATIO\_CHANNEL in the channel allocation;
- however, if element "conditional element A" was included in the channel allocation, a DA MS calculates the value of BS\_TXPWR\_RATIO\_CHANNEL as described in clause 23.5.4.3.9.

If the channel allocation that sent the MS to the current channel was not an augmented channel allocation, or if the current channel is a common control channel, the value of BS\_TXPWR\_RATIO\_CHANNEL is 0 dB.

The parameters RXLEV\_ACCESS\_MIN\_MCELL(m), MS\_TXPWR\_MAX\_MCELL(m) and BS\_TXPWR\_RATIO\_CHANNEL(m) and the modulation mode for the assessed channel classes shall be transmitted in the serving cell using an MLE broadcast message (D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

### 23.7.1.5 Path loss parameter C5

When the MLE requests that the MAC performs monitoring or scanning of the main carrier on an adjacent cell, it may also request that the MAC estimates the values of the path loss C5 for selected channel classes on that adjacent cell, based on the measurements made on the main carrier of the adjacent cell (together with the characteristics of the channel classes to be assessed). This process is referred to as neighbour cell channel class assessment.

When the MLE requests that the MAC performs monitoring of the main carrier on the serving cell, it may also request that the MAC estimates the values of the path loss C5 for selected channel classes on the serving cell, based on the measurements made on the main carrier of the serving cell (together with the characteristics of the channel classes to be assessed). This process is referred to as main carrier monitoring with assessment of channel classes.

The MS shall calculate the path loss parameter, C5, according to the following formula:

$$C5(m,n) = \text{RSSI}(n) - \text{RXLEV\_ACCESS\_MIN\_MCELL}(m) - \text{Max} ( 0, \text{MS\_TXPWR\_MAX\_MCELL}(m) - P_{\text{MSMAX}}(m) ) + \text{BS\_TXPWR\_RATIO\_CHANNEL}(m) \quad (23.19)$$

where:

- $\text{RSSI}(n)$  = averaged received signal level at MS or equivalent signal quality measurement on the monitored or scanned main carrier;
- $\text{RXLEV\_ACCESS\_MIN\_MCELL}(m)$  = the sum of minimum power level at which the BS wishes to receive MSs and the link imbalance for an MS transmitting at  $\text{MS\_TXPWR\_MAX\_MCELL}(m)$  for the assessed channel class;
- $\text{MS\_TXPWR\_MAX\_MCELL}(m)$  = maximum MS transmit power allowed for the assessed channel class;
- $P_{\text{MSMAX}}(m)$  = maximum transmit power of the MS for the modulation mode of the assessed channel class;
- $\text{BS\_TXPWR\_RATIO\_CHANNEL}(m)$  is the BS transmit power (ERP) relative to the appropriate main carrier for the assessed channel class (see note 1).

NOTE 1: For assessment of a channel class on an adjacent cell, the appropriate main carrier is the main carrier of that adjacent cell; for assessment of a channel class on the serving cell, the appropriate main carrier is the main carrier of the serving cell.

C5 and  $\text{BS\_TXPWR\_RATIO\_CHANNEL}(m)$  are expressed in dB and all the other parameters in dBm. (m) indicates the m<sup>th</sup> assessed channel class on the n<sup>th</sup> monitored or scanned main carrier.

NOTE 2: The TMC-SCAN request primitive requests scanning of a single main carrier; therefore, for scanning, n is always 1. The TMC-MONITOR-LIST request primitive may request monitoring of a list of main carriers.

C5 is calculated for the appropriate channel classes when the MS is performing neighbour cell monitoring or scanning, or main carrier monitoring. RSSI, therefore, is defined in the relevant clauses for monitoring (see clause 23.7.4) and scanning (see clause 23.7.5).

The parameters  $\text{RXLEV\_ACCESS\_MIN\_MCELL}(m)$ ,  $\text{MS\_TXPWR\_MAX\_MCELL}(m)$  and  $\text{BS\_TXPWR\_RATIO\_CHANNEL}(m)$  and the modulation mode for the assessed channel classes shall be transmitted in the serving cell using an MLE broadcast message (D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

## 23.7.2 Cell selection

The MLE may instruct the MAC to select a cell, as shown in figure 23.13, using the TMC-SELECT request primitive which shall contain a channel number parameter corresponding to the frequency of the main carrier and may contain the modulation mode and RF bandwidth of the main carrier. The MAC shall then instruct the physical layer to tune to that frequency for reception. As soon as the MS MAC has acquired synchronization on that carrier and decoded:

- for CA, the SYNC PDU and SYSINFO PDU for that cell; or
- for DA, the SYNC-DA PDU and SYSINFO-DA PDU for that cell,

it shall confirm the cell selection, by sending a TMC-SELECT confirm primitive to the MLE, and begin the serving cell measurements described in the following clause. If the TMC-SELECT request primitive is to inform the MAC of a change to a CA cell which the MAC has previously been scanning, the MS MAC may already have acquired synchronization on the new cell and decoded the SYNC and SYSINFO PDUs, in which case it may respond with a TMC-SELECT confirm primitive as soon as the physical layer has changed frequency. If the TMC-SELECT request primitive is to inform the MAC of a change to a DA cell which the MAC has previously been scanning, the MS MAC may already have acquired synchronization on the new cell and decoded the SYNC-DA PDU; the MS MAC may also have received a recent SYSINFO-DA PDU on the new cell (see notes 2 and 3), in which case it may respond with a TMC-SELECT confirm primitive as soon as the physical layer has changed frequency.

NOTE 1: When scanning a CA cell, the MS needs to receive both the SYNC PDU and the SYSINFO PDU; see clause 23.7.5.

NOTE 2: When scanning a DA cell, the MS is only required to receive the SYNC-DA PDU; see clause 23.7.5. However the MS needs to receive the SYSINFO-DA PDU before it can use a DA cell.

The SYNC-DA PDU contains all the essential information needed for the MS to decide whether it wishes to use the cell. However the SYSINFO-DA PDU contains some additional details about the cell and information needed for transmission, and the MS needs to receive the SYSINFO-DA PDU before it can use a DA cell, so the MS may prefer to receive the SYSINFO-DA PDU on a likely DA cell before confirming its decision to use that cell. The MLE instructs the MAC to attempt to receive the SYSINFO-DA PDU on a DA adjacent cell by using the TMC-CELL-READ request primitive; see clause 23.7.5.4.

NOTE 3: Some contents of the SYSINFO-DA PDU may change quite frequently. If the MS has not received a SYSINFO-DA PDU since a change in the contents then, in the case of some changes (e.g. if the CCK identifier has changed), the MS may initially miss signalling addressed to itself on the new cell.

Figure 23.13: Cell selection

This procedure is identical in the MAC for initial cell selection and cell reselection.

## 23.7.3 Serving cell measurement

### 23.7.3.0 General

Having selected and acquired synchronization on a cell as described in the previous clause, the MAC shall begin measurement of the downlink RSSI on the current channel(s) on the serving cell, as defined in clause 23.7.3.1, and use this to calculate C1 for the current channel(s) (see clause 23.7.1.1). It shall then periodically report C1 to the MLE using a TMC-MEASUREMENT indication primitive as illustrated in figures 23.14 and 23.15. This measurement of the downlink RSSI and calculation of C1 is known as surveillance and shall be based upon the cell selection or assigned channel replacement parameters (RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL) decoded on the current channel.

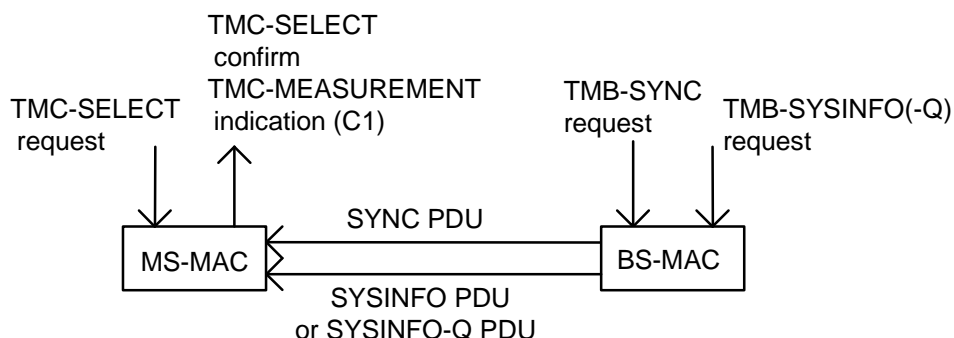

Figure 23.14: Cell selection and surveillance scenario for CA MS

**Figure 23.15: Cell selection and surveillance scenario for DA MS on QAM channel**

The MAC also performs other measurements and/or calculations relating to the performance of the serving cell:

- If the MS is not currently receiving a conforming channel, and the current channel is a non-conforming concentric or sectored channel, the MAC estimates the path loss C3 on the main carrier of the serving cell (based on the measurements made on the current channel); see notes 1 and 2. This calculation is regarded as being part of the serving cell surveillance procedure. It is described in clause 23.7.3.1.2.
- On request of the MLE, the MAC estimates the path loss C4 for a list of channel classes on the serving cell (based on the measurements made on the current channel). This is described in clause 23.7.3.1.3.
- On request of the MLE, the MAC performs monitoring of irregular carriers on the serving cell, making measurements on those irregular carriers and calculating the path loss C2. This is described in clause 23.7.4 with the other monitoring functions.
- On request of the MLE, the MAC performs monitoring of the main carrier on the serving cell, making measurements on the main carrier and calculating the path loss C2. This monitoring is regarded as being part of the serving cell surveillance procedure. It is described in clause 23.7.4 with the other monitoring functions.
- When the MAC performs monitoring of the main carrier on the serving cell: on request of the MLE, the MAC also estimates the path loss C5 for a list of channel classes on the serving cell (based on the measurements made on the main carrier). This is described in clause 23.7.4.5.

NOTE 1: If the MS is currently receiving a conforming channel, the MLE uses the value of C1 for that channel as a criterion for serving cell radio link failure (see clause 18). If the MS is receiving a non-conforming channel, the MLE uses the value of C1 for that channel as a criterion for current channel radio link failure. If the MS is not currently receiving a conforming channel, but is receiving non-conforming concentric or sectored channel(s), the MAC estimates a path loss parameter C3 for the main carrier. In this case, if the MLE has not currently requested main carrier monitoring, the MLE uses the value of C3 as a criterion for serving cell radio link failure; if the MLE has currently requested main carrier monitoring, the MLE uses the value of C2 for the main carrier as a criterion for serving cell radio link failure.

NOTE 2: If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot estimate a path loss parameter C3 for the main carrier based on the measurements made on that assigned channel. Therefore, if the MS is currently receiving only super-sectored and/or eccentric channel(s) and/or channel(s) for which it does not understand the conforming channel status, it needs to monitor the main carrier on the serving cell (path loss parameter C2) instead of performing assessment of the main carrier (path loss parameter C3); see clause 23.7.3.1.2.

Similarly, if the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot estimate the path loss parameter C4 for channel classes on the serving cell based on the measurements made on that assigned channel.

### 23.7.3.1 Downlink measurements

#### 23.7.3.1.1 Downlink measurements on current channel

##### 23.7.3.1.1.1 Signal strength measurements

The MAC shall continuously perform the measurements described in this clause on the physical channel(s) to which the MS is attached on the serving cell. Measurements shall be made on all downlink timeslots which the MAC attempts to receive within the constraints of its energy economy or dual watch or part-time reception mode or the napping procedures, and linearization and transmission requirements, or according to the monitoring pattern requirements for traffic transmission on an assigned channel.

The MAC shall measure the received RF signal strength or make an equivalent signal quality measurement and calculate a running average of at least 5 measurement samples.

These samples shall be taken during at least the last 5 s and at most the last 60 s. If less than 5 measurements were collected during this period, for example due to the constraints of an energy economy or dual watch mode, then the last 5 measurements may be used. The measurement sample duration shall be at least SD1 (see clause 10). For CA, if the BS operates in MCCH sharing then, when the MS is on the MCCH or a common SCCH, the measurements shall be performed only on the frames reserved for the BS, and not on the common frames (see clause 9).

Based upon these measurements, the path loss parameter C1 shall be calculated by the MAC at least every 5 s for the current channel.

##### 23.7.3.1.1.2 Radio Downlink Counter

The quality of the radio downlink shall be estimated from the success rate of decoding:

- the AACH when the MS is receiving a  $\pi/4$ -DQPSK or D8PSK channel; or
- the AACH-Q when the MS is receiving a QAM channel.

The MAC in a CA MS shall perform the measurements described in clause 23.7.3.1.1.3, 23.7.3.1.1.4 or 23.7.3.1.1.5 to ensure that:

- the quality on the serving cell is acceptable, in the case of measurements on a conforming  $\pi/4$ -DQPSK or D8PSK channel; or
- the quality on the current channel is acceptable, in the case of measurements on a QAM channel or on a non-conforming  $\pi/4$ -DQPSK or D8PSK channel.

For a CA MS, the criterion for relinquishing the radio downlink is based on the Radio Downlink Counter RDC, RDC-NC or RDC-Q.

The MAC in a DA MS shall perform the measurements described in clause 23.7.3.1.1.6, 23.7.3.1.1.7 or 23.7.3.1.1.8 to ensure that:

- the quality on the serving cell is acceptable, in the case of measurements on a QAM channel on the DA main carrier; or
- the quality on the current channel is acceptable, in the case of measurements on a  $\pi/4$ -DQPSK or D8PSK channel or on a QAM channel that is not on the DA main carrier.

For a DA MS, the criterion for relinquishing the radio downlink is based on the Radio Downlink Counter RDC-DA, RDC-DA-Q or RDC-DA-P.

##### 23.7.3.1.1.3 RDC on conforming $\pi/4$ -DQPSK and D8PSK channels - CA MS

When the MAC first acquires cell synchronization and begins to receive the downlink of a common control channel on a CA cell, RDC shall be initialized to a value equal to RADIO\_DOWNLINK\_TIMEOUT. The RADIO\_DOWNLINK\_TIMEOUT parameter is broadcast in the SYSINFO PDU.

If the MAC is unable to decode an AACH, RDC shall be decreased by  $N \times N.210$ . ( $N.210$  is a constant which defines the quality threshold for the MS on a  $\pi/4$ -DQPSK or D8PSK channel.) In the case of a successful reception of an AACH, RDC shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT.

The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode (except if the BS operates in MCCH sharing, see note 5); therefore,  $N$  is dependent on the MS mode of operation. Some examples are listed below.

NOTE 1: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

a) MS in normal mode:

In this mode, the MS is receiving the MCCH or a  $\pi/4$ -DQPSK common SCCH and so listens to one slot per TDMA frame. Therefore, in this case,  $N = 4$ .

b) MS in an energy economy or dual watch mode:

In this mode, the MS is not receiving all downlink slots of the common control channel.

EXAMPLE 1: For example, an MS operating with an energy group, EG5, may only be attempting to receive and decode one downlink slot per multiframe. In this case,  $N = 72$ .

c) MS receiving on an assigned channel:

In this mode, the MS is receiving one or more timeslots per TDMA frame depending upon the number of slots assigned to that channel. In this case,  $N = 4 / \text{number of timeslots per TDMA frame assigned to that channel on the downlink}$ .

d) MS in napping mode on an assigned channel:

In this mode, the MS is not receiving all downlink slots of the assigned channel.

EXAMPLE 2: For example, if an MS on a multi-slot assigned channel is only required to attempt to receive and decode one slot per TDMA frame when in napping mode then  $N = 4$  when in napping mode.

e) MS transmitting traffic on a single-slot assigned channel:

In this mode, the MS is transmitting on the uplink and is receiving the downlink according to the monitoring pattern(s) given at channel assignment. In this case,  $N = 12 / \text{number of monitoring patterns allocated to the MS}$ . This applies when 1, 2 or 3 monitoring patterns are assigned.

When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC.

A single RDC is valid for all conforming  $\pi/4$ -DQPSK and D8PSK channels on a CA cell, whatever the RF channel on which the MS decodes the AACH. Thus, if the MS moves to another conforming  $\pi/4$ -DQPSK or D8PSK channel, the RDC shall continue to run without re-initialization. If the MS moves to a non-conforming  $\pi/4$ -DQPSK or D8PSK channel, or to a QAM channel, the MAC shall store the current value of RDC; then, when the MS returns to reception of a conforming  $\pi/4$ -DQPSK or D8PSK channel, the MAC should resume updating of that RDC (using the usual value of  $N$  i.e. it shall not re-calculate the value of  $N$  taking account of the additional time since the last reception on a conforming  $\pi/4$ -DQPSK or D8PSK channel).

NOTE 2: If the MS returns to reception of a conforming  $\pi/4$ -DQPSK or D8PSK channel after a long period of receiving only non-conforming  $\pi/4$ -DQPSK or D8PSK channel(s), or QAM channel(s), the MS may choose to re-initialize the RDC to a value equal to RADIO\_DOWNLINK\_TIMEOUT.

NOTE 3: The BS should indicate the same value of the RADIO\_DOWNLINK\_TIMEOUT parameter on all conforming  $\pi/4$ -DQPSK and D8PSK channels on a CA cell.

Radio downlink failure shall be declared when the RDC falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred using a TMC-REPORT indication primitive.

NOTE 4: N.210 controls the AACH message error rate threshold at which radio downlink failure occurs on a  $\pi/4$ -DQPSK or D8PSK channel. For example, if  $N.210 = 4$ , the ratio 4 to 1 between failure and success counting gives a decreasing RDC when the message error rate exceeds 20 %. Therefore, a continuing message error rate greater than 20 % will cause radio downlink failure in this case.

NOTE 5: If the BS operates in MCCH sharing, the MS uses only the frames reserved for the BS to update RDC (though it attempts to receive and decode the relevant slot also in the common frames). Therefore, in this case, for an MS in normal mode,  $N = 144 / \text{number of reserved frames per two multiframe for the BS}$ .

#### 23.7.3.1.1.4 RDC-NC on non-conforming $\pi/4$ -DQPSK and D8PSK channels - CA MS

When a CA MS moves to a non-conforming  $\pi/4$ -DQPSK or D8PSK channel (or if the MS did not understand the conforming channel status of a  $\pi/4$ -DQPSK or D8PSK channel), the MAC shall use an independent radio downlink counter RDC-NC for that channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4). The MAC shall initialize the RDC-NC to a value equal to the assumed value of RADIO\_DOWNLINK\_TIMEOUT for that channel (see clauses 23.6.6.1 and 23.6.6.2), and shall start to decrease or increase RDC-NC according to failure to decode or successful reception of the AACH as described below. On receiving a SYSINFO PDU on that channel, if the value of the RADIO\_DOWNLINK\_TIMEOUT parameter in the SYSINFO PDU is different from the assumed value, the MAC shall make a correction by adding the difference between the true value and the assumed value of the RADIO\_DOWNLINK\_TIMEOUT to the current value of RDC-NC.

As in clause 23.7.3.1.1.3:

- If the MAC is unable to decode an AACH, RDC-NC shall be decreased by  $N \times N.210$ . In the case of a successful reception of an AACH, RDC-NC shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT for that channel.
- The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode; therefore,  $N$  is dependent on the MS mode of operation. Examples c), d) and e) in clause 23.7.3.1.1.3 apply. When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC-NC.

NOTE: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

RDC-NC is valid only for the current channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

Radio downlink failure for the current channel shall be declared when the RDC-NC falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred on that channel using a TMC-REPORT indication primitive.

#### 23.7.3.1.1.5 RDC-Q on QAM channels - CA MS

When a CA MS moves to a QAM channel, the MAC shall use an independent radio downlink counter RDC-Q for that channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

If the MS is moving from one conforming QAM channel to another conforming QAM channel with the same carrier frequency, RF bandwidth and BS transmit power relative to the main carrier, the MS may continue use of the previous RDC-Q without re-initialization. Otherwise the MAC shall initialize the RDC-Q to a value equal to the assumed value of RADIO\_DOWNLINK\_TIMEOUT for that channel (see clause 23.6.6.3), and shall start to decrease or increase RDC-Q according to failure to decode or successful reception of the AACH-Q as described below. On receiving a SYSINFO-Q PDU on that channel, if the value of the RADIO\_DOWNLINK\_TIMEOUT parameter in the SYSINFO-Q PDU is different from the assumed value, the MAC shall make a correction by adding the difference between the true value and the assumed value of the RADIO\_DOWNLINK\_TIMEOUT to the current value of RDC-Q.

If the MAC is unable to decode an AACH-Q, RDC-Q shall be decreased by  $N \times N.209$ . ( $N.209$  is a constant which defines the quality threshold for the MS on a QAM channel.) In the case of a successful reception of an AACH-Q, RDC-Q shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT for that channel.

The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode; therefore,  $N$  is dependent on the MS mode of operation. Examples c) and d) in clause 23.7.3.1.1.3 apply. When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC-Q.

NOTE 1: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

RDC-Q is valid only for the current channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

Radio downlink failure for the current channel shall be declared when the RDC-Q falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred on that channel using a TMC-REPORT indication primitive.

NOTE 2:  $N_{.209}$  on a QAM channel is equivalent to  $N_{.210}$  on a  $\pi/4$ -DQPSK or D8PSK channel. It controls the AACH-Q message error rate threshold at which radio downlink failure occurs on a QAM channel. The value of  $N_{.209}$  may be different from the value of  $N_{.210}$ .

#### 23.7.3.1.1.6 RDC-DA on QAM channels on the DA main carrier - DA MS

When the MAC first acquires cell synchronization and begins to receive the downlink of a common control channel on a DA cell, RDC-DA shall be initialized to a value equal to RADIO\_DOWNLINK\_TIMEOUT. The RADIO\_DOWNLINK\_TIMEOUT parameter is broadcast in the SYSINFO-DA PDU.

If the MAC is unable to decode an AACH-Q, RDC-DA shall be decreased by  $N \times N_{.209}$ . ( $N_{.209}$  is a constant which defines the quality threshold for the MS on a QAM channel.) In the case of a successful reception of an AACH-Q, RDC-DA shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT.

The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode; therefore,  $N$  is dependent on the MS mode of operation. Some examples are listed below.

NOTE 1: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

a) MS in normal mode on a single-slot common control channel:

In this mode, the MS is receiving a single-slot MCCH-Q or a QAM common SCCH and so listens to one slot per TDMA frame. Therefore, in this case,  $N = 4$ .

b) MS in normal mode on a multi-slot common control channel:

In this mode, the MS is receiving a multi-slot MCCH-Q and so listens to more than one slot per TDMA frame. In this case,  $N = 4 / \text{number of timeslots per TDMA frame comprising the MCCH-Q}$ .

c) MS in part-time reception mode on a multi-slot common control channel:

In this mode, the MS may only be attempting to receive one slot of the multi-slot MCCH-Q per TDMA frame. In this case,  $N = 4$  when the MS is using part-time reception.

d) MS in an energy economy or dual watch mode:

In this mode, the MS is not receiving all downlink slots of the common control channel.

EXAMPLE 1: For example, an MS operating with an energy group, EG5, on a single-slot common control channel (or on a multi-slot MCCH-Q if enhanced energy economy is available) may only be attempting to receive and decode one downlink slot per multiframe. In this case,  $N = 72$ .

e) MS receiving on an assigned channel:

In this mode, the MS is receiving one or more timeslots per TDMA frame depending upon the number of slots assigned to that channel. In this case,  $N = 4 / \text{number of timeslots per TDMA frame assigned to that channel on the downlink}$ .

f) MS in napping mode on an assigned channel:

In this mode, the MS is not receiving all downlink slots of the assigned channel.

EXAMPLE 2: For example, if an MS on a multi-slot assigned channel is only required to attempt to receive and decode one slot per TDMA frame when in napping mode then  $N = 4$  when in napping mode.

When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC-DA.

A single RDC-DA is valid for all QAM channels on the DA main carrier i.e. for QAM common control channels and for conforming assigned QAM channels with the same carrier frequency and RF bandwidth as the DA main carrier and with BS transmit power relative to the main carrier of 0 dB. Thus, if the MS moves to another QAM channel on the DA main carrier, the RDC-DA shall continue to run without re-initialization. If the MS moves to a QAM channel that is not on the DA main carrier, or to a  $\pi/4$ -DQPSK or D8PSK channel, the MAC shall store the current value of RDC-DA; then, when the MS returns to reception of a QAM channel on the DA main carrier, the MAC should resume updating of that RDC-DA (using the usual value of  $N$  i.e. it shall not re-calculate the value of  $N$  taking account of the additional time since the last reception on a QAM channel on the DA main carrier).

NOTE 2: If the MS returns to reception of a QAM channel on the DA main carrier after a long period of receiving only QAM channel(s) not on the DA main carrier, or  $\pi/4$ -DQPSK or D8PSK channel(s), the MS may choose to re-initialize the RDC-DA to a value equal to RADIO\_DOWNLINK\_TIMEOUT.

NOTE 3: The BS should indicate the same value of the RADIO\_DOWNLINK\_TIMEOUT parameter on all QAM channels on the DA main carrier.

Radio downlink failure shall be declared when the RDC-DA falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred using a TMC-REPORT indication primitive.

NOTE 4:  $N_{.209}$  controls the AACH-Q message error rate threshold at which radio downlink failure occurs on a QAM channel. For example, if  $N_{.209} = 4$ , the ratio 4 to 1 between failure and success counting gives a decreasing RDC-DA when the message error rate exceeds 20 %. Therefore, a continuing message error rate greater than 20 % will cause radio downlink failure in this case.

#### 23.7.3.1.1.7 RDC-DA-Q on QAM channels not on the DA main carrier - DA MS

When a DA MS moves to a QAM channel that is not on the DA main carrier, the MAC shall use an independent radio downlink counter RDC-DA-Q for that channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

If the MS is moving from one conforming QAM channel to another conforming QAM channel with the same carrier frequency, RF bandwidth and BS transmit power relative to the main carrier, the MS may continue use of the previous RDC-DA-Q without re-initialization. Otherwise the MAC shall initialize the RDC-DA-Q to a value equal to the assumed value of RADIO\_DOWNLINK\_TIMEOUT for that channel (see clause 23.6.11.1), and shall start to decrease or increase RDC-DA-Q according to failure to decode or successful reception of the AACH-Q as described below. On receiving a SYSINFO-DA PDU on that channel, if the value of the RADIO\_DOWNLINK\_TIMEOUT parameter in the SYSINFO-DA PDU is different from the assumed value, the MAC shall make a correction by adding the difference between the true value and the assumed value of the RADIO\_DOWNLINK\_TIMEOUT to the current value of RDC-DA-Q.

As in clause 23.7.3.1.1.6:

- If the MAC is unable to decode an AACH-Q, RDC-DA-Q shall be decreased by  $N \times N_{.209}$ . In the case of a successful reception of an AACH-Q, RDC-DA-Q shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT for that channel.
- The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode; therefore,  $N$  is dependent on the MS mode of operation. Examples e) and f) in clause 23.7.3.1.1.6 apply. When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC-DA-Q.

NOTE: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

RDC-DA-Q is valid only for the current channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

Radio downlink failure for the current channel shall be declared when the RDC-DA-Q falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred on that channel using a TMC-REPORT indication primitive.

#### 23.7.3.1.1.8 RDC-DA-P on $\pi/4$ -DQPSK and D8PSK channels - DA MS

When a DA MS moves to a  $\pi/4$ -DQPSK or D8PSK channel, the MAC shall use an independent radio downlink counter RDC-DA-P for that channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

If the MS is moving from one conforming  $\pi/4$ -DQPSK or D8PSK channel to another conforming  $\pi/4$ -DQPSK or D8PSK channel with the same carrier frequency and BS transmit power relative to the main carrier, the MS may continue use of the previous RDC-DA-P without re-initialization. Otherwise the MAC shall initialize the RDC-DA-P to a value equal to the assumed value of RADIO\_DOWNLINK\_TIMEOUT for that channel (see clauses 23.6.11.2 and 23.6.11.3), and shall start to decrease or increase RDC-DA-P according to failure to decode or successful reception of the AACH as described below. On receiving a SYSINFO PDU on that channel, if the value of the RADIO\_DOWNLINK\_TIMEOUT parameter in the SYSINFO PDU is different from the assumed value, the MAC shall make a correction by adding the difference between the true value and the assumed value of the RADIO\_DOWNLINK\_TIMEOUT to the current value of RDC-DA-P.

If the MAC is unable to decode an AACH, RDC-DA-P shall be decreased by  $N \times N.210$ . ( $N.210$  is a constant which defines the quality threshold for the MS on a  $\pi/4$ -DQPSK or D8PSK channel.) In the case of a successful reception of an AACH, RDC-DA-P shall be increased by  $N$  but shall not be increased above the value of RADIO\_DOWNLINK\_TIMEOUT for that channel.

The parameter  $N$  is equal to the number of timeslots between successive downlink slots which the MS is attempting to receive and decode; therefore,  $N$  is dependent on the MS mode of operation. Examples e) and f) in clause 23.7.3.1.1.6 apply. Another example is as follows:

- MS transmitting traffic on a single-slot assigned channel:

In this mode, the MS is transmitting on the uplink and is receiving the downlink according to the monitoring pattern(s) given at channel assignment. In this case,  $N = 12 / \text{number of monitoring patterns allocated to the MS}$ . This applies when 1, 2 or 3 monitoring patterns are assigned.

When the mode of operation of the MS is changed, the corresponding value of  $N$  shall be calculated by the MAC and used for updating RDC-DA-P.

NOTE 1: The parameter  $N$  includes the downlink slot that the MS is attempting to receive and decode, in addition to the gap between downlink slots that the MS attempts to receive and decode.

RDC-DA-P is valid only for the current channel (except possibly in the case of concurrent channels; see clause 23.7.3.1.4).

Radio downlink failure for the current channel shall be declared when the RDC-DA-P falls below 0. If this happens, the MAC shall inform the MLE that radio downlink failure has occurred on that channel using a TMC-REPORT indication primitive.

NOTE 2:  $N.210$  on a  $\pi/4$ -DQPSK or D8PSK channel is equivalent to  $N.209$  on a QAM channel. It controls the AACH message error rate threshold at which radio downlink failure occurs on a  $\pi/4$ -DQPSK or D8PSK channel. The value of  $N.210$  may be different from the value of  $N.209$ .

#### 23.7.3.1.2 Assessment of the main carrier from a non-conforming assigned channel

As defined in clause 23.7.3.1.1.1, having selected and acquired synchronization on a cell, the MAC begins measurement of the downlink RSSI on the current channel(s) on the serving cell, and uses this to calculate  $C1$  for the current channel(s). It then periodically reports each  $C1$  to the MLE using a TMC-MEASUREMENT indication primitive.

When the MS is not currently receiving a conforming channel, and the current channel is a non-conforming concentric or sectorized channel, the following additional procedure shall apply.

When the MAC calculates C1 for the current channel on the serving cell, it shall also estimate the path loss C3 on the main carrier of the serving cell - based on the RF signal strength or equivalent measurements made on the current channel (see clause 23.7.1.3). The MAC shall include the C3 result in the TMC-MEASUREMENT indication primitive whenever it reports C1 to the MLE.

When the MAC calculates C3:

- for CA, it shall use the cell selection parameters (RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL) last received in the SYSINFO PDU on a conforming  $\pi/4$ -DQPSK channel in this cell;
- for DA, it shall use the cell selection parameters (RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL) last received in the SYSINFO-DA PDU on a conforming QAM channel in this cell with the same bandwidth as the main carrier or (optionally) in the SYNC-DA PDU;
- it shall use the BS transmit power relative to the main carrier for the current channel, as received in the channel allocation (or as calculated from element "conditional element A" in the channel allocation).

NOTE: Additionally, if the MLE prefers the MAC to make direct measurements of the path loss on the main carrier, the MLE may request monitoring of the main carrier on the serving cell (see clause 23.7.4).

If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform assessment of the main carrier based on the measurements made on that assigned channel. Therefore the MS needs to perform monitoring of the main carrier on the serving cell (path loss parameter C2) instead of performing assessment of the main carrier (path loss parameter C3). Thus, when the MS is not currently receiving a concentric or sectored channel, the MLE requests that the MAC performs monitoring of the main carrier on the serving cell, by including the main carrier of the serving cell in the TMC-MONITOR-LIST request primitive (see clause 18 and clause 23.7.4).

### 23.7.3.1.3 Serving cell channel class assessment

Serving cell channel class assessment is an MS function which uses measurements made on the current channel to estimate the path loss C4 for selected channel classes. The current channel may be either a conforming channel or a non-conforming concentric or sectored channel (see note 3).

Figure 23.16 illustrates how the MLE initiates the procedure for serving cell channel class assessment. The MLE sends a TMC-ASSESSMENT-LIST request primitive including a list of channel classes to be assessed, together with the characteristics of each channel class to be assessed.

NOTE 1: The characteristics of each channel class to be assessed include the modulation mode for that channel class, the maximum MS transmit power for that channel class, the minimum RX access level for that channel class and the BS transmit power relative to the main carrier of the serving cell.

The MAC shall measure the received RF signal strength or equivalent on the current channel as described in clause 23.7.3.1.1.1. Based on these measurements, the MAC shall estimate the path loss C4 for each of the channel classes (see clause 23.7.1.4). The MAC shall estimate the path loss C4 for each channel class at least every 5 s.

The result of the TMC-ASSESSMENT-LIST request primitive shall be contained in the TMC-ASSESSMENT indication primitive. The MAC shall estimate C4 for each channel class and shall periodically pass the results to the MLE using the TMC-ASSESSMENT indication primitive.

When the MAC calculates C4 for a channel class, it shall use the values of the channel class characteristics parameters provided by the MLE (received by the MLE in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU). It shall also use the BS transmit power relative to the main carrier for the current channel. (This is assumed to be 0 dB unless the current channel is an assigned channel allocated with an augmented channel allocation.)

A TMC-ASSESSMENT-LIST request primitive with an empty channel class list shall inform the MAC to cease serving cell channel class assessment.

NOTE 2: Alternatively (or additionally) to requesting serving cell channel class assessment, if the MLE wishes the channel classes on the serving cell to be assessed using measurements made on the main carrier, the MLE may request main carrier monitoring with assessment of channel classes (see clause 23.7.4.5).

NOTE 3: If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform serving cell channel class assessment based on the measurements made on that assigned channel. Therefore, if the MS is currently receiving only super-sectored and/or eccentric channel(s) and/or channel(s) for which it does not understand the conforming channel status, and it wishes to perform assessment of channel classes, it needs to perform main carrier monitoring with assessment of channel classes (see clause 23.7.4.5).

**Figure 23.16: Scenario for serving cell channel class assessment**

#### 23.7.3.1.4 Concurrent channels on the serving cell

If the MAC is using concurrent channels on the serving cell, it shall perform the measurements and fulfil the requirements of providing the C1 parameter to the MLE (and C3 when appropriate), and information about the channel quality, in a way which is equivalent to or better than the method described below.

If the MAC is using concurrent channels, it may measure and report C1 independently for each individual channel.

Alternatively, if two or more of the concurrent channels are conforming channels with the same RF parameters, the MAC may make a single C1 calculation for those channels, based on measurements made on the combination of those channels. For the purposes of this procedure, the channels may be regarded as having the same RF parameters if they have the same value of  $P_{MSMAX}$ ,  $RXLEV\_ACCESS\_MIN$ ,  $MS\_TXPWR\_MAX\_CELL$ , BS transmit power relative to the main carrier, carrier frequency and RF bandwidth.

If none of the concurrent channels is a conforming channel, and the MS is receiving one or more non-conforming concentric or sectored channels, the MAC is required to provide an estimate of the path loss C3 to the MLE (see clause 23.7.3.1.2). The MAC shall provide C3 to the MLE when it provides C1, for at least one of the non-conforming concentric or sectored channels (see note 1).

NOTE 1: If any of the concurrent channels are super-sectored or eccentric, or if the MS did not understand the conforming channel status for any of the concurrent channels, the MS cannot perform assessment of the main carrier based on the measurements made on those channels.

If the MLE initiates the procedure for serving cell channel class assessment, the MAC may use the measurements made on any of the current concentric or sectored channels to estimate the path loss C4 for the selected channel classes; however, if the MS is currently using both concentric and sectored channel(s), the MS should use the measurements made on a concentric channel in preference to measurements made on a sectored channel. If two or more of the concurrent channels are conforming channels with the same RF parameters (as defined above), the MAC may estimate the path loss C4 based on measurements made on the combination of those channels.

NOTE 2: If the MS is on a super-sectored or eccentric assigned channel, or if the MS did not understand the conforming channel status for the assigned channel, it cannot perform serving cell channel class assessment based on the measurements made on that assigned channel.

For a CA MS:

- If the MS is using concurrent conforming  $\pi/4$ -DQPSK and/or D8PSK channels, the MAC shall use a single radio downlink counter RDC for those channels, as defined in clause 23.7.3.1.1.3.

NOTE 3: The BS should indicate the same value of the `RADIO_DOWNLINK_TIMEOUT` parameter on all conforming  $\pi/4$ -DQPSK and D8PSK channels on the cell.

- If the MS is using concurrent non-conforming  $\pi/4$ -DQPSK and/or D8PSK channels with the same carrier frequency, BS transmit power relative to the main carrier and value of `RADIO_DOWNLINK_TIMEOUT`, the MAC may use a single radio downlink counter RDC-NC for those channels.

- If the MS is using concurrent conforming QAM channels with the same carrier frequency, RF bandwidth, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-Q for those channels.
- If the MS is using concurrent non-conforming QAM channels with the same carrier frequency, RF bandwidth, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-Q for those channels.
- Otherwise the MAC shall use separate radio downlink counters for concurrent channels.

For a DA MS:

- If the MS is using concurrent QAM channels on the DA main carrier, the MAC shall use a single radio downlink counter RDC-DA for those channels.

NOTE 4: The BS should indicate the same value of the RADIO\_DOWNLINK\_TIMEOUT parameter on all channels on the DA main carrier.

- For QAM channels not on the DA main carrier:
  - If the MS is using concurrent conforming QAM channels with the same carrier frequency, RF bandwidth, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-DA-Q for those channels.
  - If the MS is using concurrent non-conforming QAM channels with the same carrier frequency, RF bandwidth, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-DA-Q for those channels.
- If the MS is using concurrent conforming  $\pi/4$ -DQPSK and/or D8PSK channels with the same carrier frequency, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-DA-P for those channels.
- If the MS is using concurrent non-conforming  $\pi/4$ -DQPSK and/or D8PSK channels with the same carrier frequency, BS transmit power relative to the main carrier and value of RADIO\_DOWNLINK\_TIMEOUT, the MAC may use a single radio downlink counter RDC-DA-P for those channels.
- Otherwise the MAC shall use separate radio downlink counters for concurrent channels.

### 23.7.3.2 Uplink measurements

The criterion for determining the relinquishment of the radio uplink in the BS may be based upon uplink received signal strength measurement or an equivalent signal quality measurement and a measurement of the path delay from MS to BS derived from the time at which uplink slots are received at the BS.

The measurement of uplink received signal strength or quality may be used by the BS as a criterion to relinquish the radio link. The BS may inform the MS if this happens by sending a MAC-RESOURCE PDU which includes the optional "Power control" element with a value set to "Radio uplink failure". On receiving this, the MS MAC shall inform the MLE using a TMC-REPORT indication primitive. (The MLE action on receipt of this report depends on whether the current channel is a conforming channel; see clause 18.)

The measurement of uplink path delay may also be used by the BS as a criterion to relinquish the radio link. This allows the BS to limit the MS-BS distance and prevent the MS grossly exceeding the planned cell boundaries. The BS may inform the MS if this happens by sending a MAC-RESOURCE PDU which includes the optional "Power control" element with a value set to "maximum path delay exceeded" or "maximum path delay almost exceeded" (see note). On receiving either of these, the MS MAC shall inform the MLE using a TMC-REPORT indication primitive in order to initiate the MLE cell reselection procedures.

NOTE: The interpretation "maximum path delay almost exceeded" is applicable only to MSs that support the AGA service (see annex O).

## 23.7.4 Monitoring

### 23.7.4.0 General

The monitoring procedure is an MS function which measures the signal strength of carriers other than the carrier of the current channel and calculates C2. The monitoring procedure may be used for neighbour cell monitoring, irregular channel monitoring and main carrier monitoring.

Neighbour cell monitoring is an MS function which measures the signal strength of the main carrier on adjacent cells and calculates C2. The cell selection parameters for the adjacent cell may be broadcast on the serving cell for the C2 calculation. Monitoring is used when the MS is not synchronized to the adjacent cells and so cannot decode the adjacent cell BNCH (for a CA adjacent cell) or BSCH-Q (for a DA adjacent cell).

For neighbour cell monitoring, when the MLE initiates the monitoring procedure in the MAC, the MLE may also request assessment of the path loss (C5) for a number of channel classes on an adjacent cell (using the measurements made on the main carrier of that adjacent cell).

Irregular channel monitoring is an MS function which measures the signal strength of irregular carriers on the serving cell or on adjacent cells. The parameters for the irregular carrier are broadcast on the serving cell for the C2 calculation.

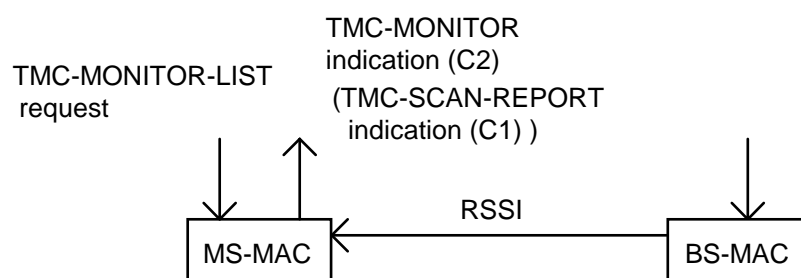

Main carrier monitoring is an MS function which measures the signal strength of the main carrier of the serving cell and calculates C2. The parameters for the main carrier are broadcast on the serving cell.

For main carrier monitoring, when the MLE initiates the monitoring procedure in the MAC, the MLE may also request assessment of the path loss (C5) for a number of channel classes on the serving cell (using the measurements made on the main carrier of the serving cell).

The following clauses describe the monitoring procedure. The MS MAC shall perform the measurements and fulfil the requirements of providing the C2 parameter to the MLE in a way which is equivalent to or better than the method described.

### 23.7.4.1 Monitoring scenario

Figure 23.17 illustrates how the MLE initiates the monitoring procedure in the MAC by sending TMC-MONITOR-LIST request primitive along with a list of channel numbers which correspond to the frequencies of the RF channels (carriers) to be monitored. The channel numbers in the list may correspond to a combination of adjacent cell main carriers, serving cell irregular carriers and/or adjacent cell irregular carriers, and may include the main carrier of the serving cell.

**Figure 23.17: Monitoring scenario**

The result of the TMC-MONITOR-LIST request primitive shall be contained in the TMC-MONITOR indication primitive. The MAC shall make the measurements needed to calculate C2 for each RF channel and shall periodically pass the result for each one using the TMC-MONITOR indication primitive.

**NOTE 1:** It is possible that the MLE may request neighbour cell monitoring of a channel that the MAC is currently receiving, for example, if a CA MS is currently receiving an assigned channel on a DA main carrier, or if a DA MS is currently receiving an assigned channel on the (if any) local CA main carrier.

The following points apply for neighbour cell monitoring:

- When monitoring a CA adjacent cell, the MAC shall use the adjacent cell parameters provided by the MLE for the C2 calculation (if they have been received on the serving cell by the MLE in the D-NWRK-BROADCAST PDU (or D-NWRK-BROADCAST-DA PDU, see note 2)). If the MS has not received these, the MAC shall use cell selection parameters as specified in clause 23.7.1.2 to calculate C2 instead.

NOTE 2: MSs generally obtain information about the main carrier on CA adjacent cells from the D-NWRK-BROADCAST PDU. However DA MSs may obtain information about the main carrier of the (if any) local CA cell from the D-NWRK-BROADCAST-DA PDU. (They obtain information about the channel classes and/or irregular channels on the local CA cell from the D-NWRK-BROADCAST-EXTENSION PDU.)

- When monitoring a DA adjacent cell:
  - the TMC-MONITOR-LIST request primitive indicates the RF bandwidth of the adjacent cell main carrier (received on the serving cell by the MLE in the D-NWRK-BROADCAST-DA PDU);
  - the MAC shall use the adjacent cell parameters provided by the MLE for the C2 calculation (if they have been received on the serving cell by the MLE in the D-NWRK-BROADCAST-DA PDU). If the MS has not received these, the MAC shall use cell selection parameters as specified in clause 23.7.1.2 to calculate C2 instead.

NOTE 3: For bandwidths greater than 25 kHz, the carrier number in the D-NWRK-BROADCAST-DA PDU refers to the centre frequency of the lowest 25 kHz comprising the carrier (as for a channel allocation, see clause 21.5.2).

- If the MS has already acquired synchronization on an adjacent cell and it has decoded the broadcast parameters needed to calculate C1, the MAC shall report the updated value of C1 for the adjacent cell using the TMC-SCAN-REPORT indication primitive instead of reporting C2 for that cell.

The following points apply for irregular channel monitoring:

- For each irregular carrier to be monitored, the TMC-MONITOR-LIST request primitive indicates the modulation mode and the RF bandwidth (received on the serving cell by the MLE in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).
- The MLE provides the parameters for the C2 calculation (received on the serving cell by the MLE in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

NOTE 4: For bandwidths greater than 25 kHz, the carrier number in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU refers to the centre frequency of the lowest 25 kHz comprising the carrier (as for a channel allocation, see clause 21.5.2).

The following points apply for main carrier monitoring:

- A CA MS shall use the parameters RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell for the C2 calculation.
- A DA MS shall use the parameters RXLEV\_ACCESS\_MIN and MS\_TXPWR\_MAX\_CELL last received on a conforming QAM channel on the serving cell with the same bandwidth as the main carrier for the C2 calculation.

A TMC-MONITOR-LIST request primitive with an empty channel list shall inform the MAC to cease monitoring.

#### 23.7.4.2 Monitoring measurements

The MAC shall measure the received RF signal strength or equivalent signal quality for all RF channels (carriers) of the monitor list.

As far as possible the same number of measurement samples shall be taken for all RF channels and the measurement samples shall be uniformly distributed over the averaging period.

The MAC shall measure the received RF signal strength or make an equivalent signal quality measurement for all RF channels of the monitor list. For each RF channel, it shall calculate a running average of at least 5 measurement samples. These samples shall be taken during at least the last 5 s and at most the last 60 s. If less than 5 measurements were collected during this period, for example due to the constraints of an energy economy or dual watch mode, then the last 5 measurements may be used. The measurement sample duration shall be at least SD1 (refer to clause 10). Using the average of these measurements, the MAC shall calculate the parameter C2 at least every 5 s. In the case of neighbour cell monitoring, the MAC may in addition calculate the parameter C1 for all RF channels of the monitoring list with which it has already synchronized and decoded the BNCH (for a CA cell) or BSCH-Q (for a DA cell).

### 23.7.4.3 Signal strength measurement

The RSSI measurements or equivalent signal quality measurements shall be made during the non-assigned or non-used timeslots of the physical channel(s) to which the MS is attached.

- EXAMPLE:
- for a receiving or idle MS, during the uplink slots of the physical channel;
  - for a transmitting MS, during the downlink slots not already assigned to serving cell reception as defined by the monitoring pattern(s) allocated to the MS;
  - for an MS in full duplex, during the unused uplink slot of the control frame;
  - when the MS is not transmitting, during the downlink slots in which the MS is not required to receive, as a result of the napping or energy economy or part-time reception procedures.

The measurements shall be made whenever possible, taking into account the mode of operation and the frequency switching capability of the MS. However, the overall frequency of measurement, taking into account all RF channels, need not exceed the following rate:

- |                                  |  |
|----------------------------------|--|
| MS in half duplex RX or TX mode: | 6 measurements per multiframe period;  |
| MS in idle mode:                 | 1 measurement per 3 downlink TDMA frames of the MCCH or single-slot MCCH-Q or common SCCH; |
|                                  | 6 measurements per multiframe period of a multi-slot MCCH-Q.                               |

If the RF channel does not operate in timesharing mode, the measurement sample duration shall be at least SD2 as defined in clause 10.

If the RF channel operates in timesharing mode and if the MS has knowledge of the timesharing synchronization, the MS shall perform the measurements only during the timeslots exclusively reserved to the monitored channel. If no active timeslots can be found that coincide with the monitoring periods, the measurement shall not be performed on this RF channel. If some can be found, the measurement sample duration shall be at least SD1.

If the RF channel operates in timesharing mode and if the MS does not have knowledge of the timesharing synchronization, the measurement sample duration shall be at least SD1 and several measurements are allowed on the same RF channel during one monitoring period. The MS shall calculate the average of the 5 samples showing the highest RF signal strength during the preceding 10 s, these samples being separated by at least 50 ms.

- NOTE: Timesharing mode may apply for neighbour cell monitoring on a CA adjacent cell (indicated by the MLE in the TMC-MONITOR-LIST request primitive); timesharing mode may apply for main carrier monitoring on a CA serving cell (indicated by the SYNC PDU on the serving cell); timesharing mode does not apply for irregular channel monitoring or for neighbour cell monitoring on a DA adjacent cell or for main carrier monitoring on a DA serving cell.

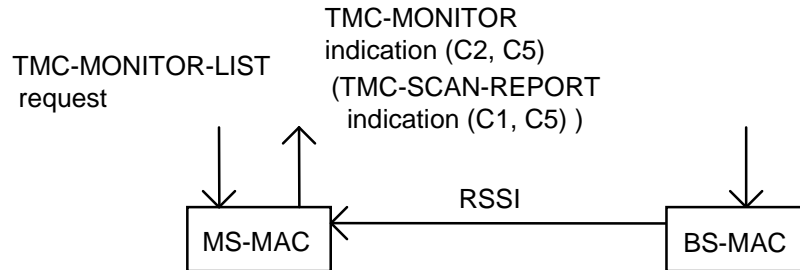

### 23.7.4.4 Neighbour cell monitoring with assessment of channel classes

When the MLE initiates the monitoring procedure for the main carrier on an adjacent cell, it may also request assessment of the path loss (C5) for a number of channel classes on that adjacent cell.

Figure 23.18 illustrates how the MLE initiates the neighbour cell monitoring procedure with assessment of channel classes on the adjacent cell(s). The MLE sends a TMC-MONITOR-LIST request primitive including one or more channel numbers, of which at least one corresponds to the frequency of an adjacent cell main carrier to be monitored. For each adjacent cell main carrier to be monitored, the MLE may include a list of channel classes to be assessed (together with the characteristics of each channel class to be assessed).

NOTE 1: The characteristics of each channel class to be assessed include the modulation mode for that channel class, the maximum MS transmit power for that channel class, the minimum RX access level for that channel class and the BS transmit power relative to the main carrier of that adjacent cell.

NOTE 2: For monitoring of a DA adjacent cell, the TMC-MONITOR-LIST request primitive also indicates the RF bandwidth of the main carrier of that adjacent cell.

**Figure 23.18: Neighbour cell monitoring scenario with assessment of channel classes**

The MAC shall make the measurements needed to calculate C2 for the adjacent cell main carrier (as defined in clauses 23.7.4.2 and 23.7.4.3), and shall then estimate the path loss (C5) for each of the channel classes to be assessed - based on the RSSI or equivalent measurements made on the monitored main carrier. The MAC shall then pass the C2 result and the C5 results to the MLE using the TMC-MONITOR indication primitive.

The MAC shall make the measurements needed to calculate C2 for each adjacent cell main carrier and shall periodically pass the result for each one, and also the corresponding C5 results for each one, using the TMC-MONITOR indication primitive.

The MAC shall use the adjacent cell parameters provided by the MLE for the C2 calculation (if they have been received on the serving cell by the MLE in the D-NWRK-BROADCAST or D-NWRK-BROADCAST-DA PDU). If the MS has not received these, the MAC shall use cell selection parameters as specified in clause 23.7.1.2 to calculate C2 instead. The MAC shall use the values of the channel class characteristics parameters provided by the MLE for the C5 calculation (received on the serving cell by the MLE in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

If the MS has already acquired synchronization on an adjacent cell and it has decoded the broadcast parameters needed to calculate C1, the MAC shall report the updated value of C1 for the adjacent cell using the TMC-SCAN-REPORT indication primitive instead of reporting C2 for that cell. In this case the MAC shall include the C5 results in the TMC-SCAN-REPORT indication primitive.

### 23.7.4.5 Main carrier monitoring with assessment of channel classes

When the MLE initiates the monitoring procedure for the main carrier on the serving cell, it may also request assessment of the path loss (C5) for a number of channel classes on the serving cell.

Figure 23.19 illustrates how the MLE initiates the main carrier monitoring procedure with assessment of channel classes on the serving cell. The MLE sends a TMC-MONITOR-LIST request primitive including one or more channel numbers, one of which corresponds to the frequency of the main carrier on the serving cell. The MLE also includes a list of channel classes to be assessed (together with the characteristics of each channel class to be assessed).

NOTE: The characteristics of each channel class to be assessed include the modulation mode for that channel class, the maximum MS transmit power for that channel class, the minimum RX access level for that channel class and the BS transmit power relative to the main carrier of the serving cell.

**Figure 23.19: Main carrier monitoring scenario with assessment of channel classes**

The MAC shall make the measurements needed to calculate C2 for the main carrier (as defined in clauses 23.7.4.2 and 23.7.4.3), and shall then estimate the path loss (C5) for each of the channel classes to be assessed - based on the RSSI or equivalent measurements made on the main carrier. The MAC shall then pass the C2 result and the C5 results to the MLE using the TMC-MONITOR indication primitive.

The MAC shall make the measurements needed to calculate C2 for the main carrier and shall periodically pass the result, and also the corresponding C5 results, using the TMC-MONITOR indication primitive.

The MAC in a CA MS shall use the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a conforming  $\pi/4$ -DQPSK channel on the serving cell for the C2 calculation. The MAC shall use the values of the channel class characteristics parameters provided by the MLE for the C5 calculation (received by the MLE in the D-NWRK-BROADCAST-EXTENSION PDU).

The MAC in a DA MS shall use the parameters `RXLEV_ACCESS_MIN` and `MS_TXPWR_MAX_CELL` last received on a conforming QAM channel on the serving cell with the same bandwidth as the main carrier for the C2 calculation. The MAC shall use the values of the channel class characteristics parameters provided by the MLE for the C5 calculation (received by the MLE in the D-NWRK-BROADCAST-DA PDU).

## 23.7.5 Scanning

### 23.7.5.0 General

Scanning is an MS function which measures the signal strength on the main carrier of the adjacent cells and calculates C1 using the adjacent cell parameters broadcast on the relevant adjacent cell. It is used when the MS obtains synchronization to the adjacent cell and is able to decode:

- the adjacent cell BSCH and BNCH for a CA adjacent cell; or
- the adjacent cell BSCH-Q for a DA adjacent cell.

When the MLE initiates the scanning procedure in the MAC, it may also request assessment of the path loss (C5) for a number of channel classes on that adjacent cell (using the measurements made on the main carrier of the adjacent cell).

The following clauses describe the scanning procedure. The MS MAC shall perform the measurements and fulfil the requirements of providing the C1 parameter to the MLE in a way which is equivalent to or better than the method described.

### 23.7.5.1 Scanning scenario

Figures 23.20 and 23.21 illustrate how the MLE initiates the scanning procedure in the MAC by sending TMC-SCAN request primitive along with a channel number which corresponds to the frequency of the adjacent cell main carrier to be scanned, the modulation mode and RF bandwidth of the adjacent cell main carrier to be scanned, and a scanning measurement method to indicate whether foreground, background or interrupted scanning is to be used.

The MAC shall make the measurements needed to calculate C1 for the adjacent cell RF channel (carrier) and shall pass the result using TMC-SCAN confirm primitive. The MS shall use the cell selection parameters broadcast on the adjacent cell for the C1 calculation.

Figure 23.20: Scanning scenario for CA adjacent cell

Figure 23.21: Scanning scenario for DA adjacent cell

## 23.7.5.2 Scanning measurement

### 23.7.5.2.0 General

Scanning shall comprise of achieving synchronization with an adjacent cell, measuring the received signal strength or an equivalent signal quality and decoding:

- the BSCH and BNCH broadcast on the adjacent cell for a CA adjacent cell; or
- the BSCH-Q broadcast on the adjacent cell for a DA adjacent cell (see note).

NOTE: When scanning a DA cell, the SYNC-DA PDU (carried in the BSCH-Q) contains all the essential information needed for the MS to decide whether it wishes to use the cell. However the SYSINFO-DA PDU contains some additional details about the cell and information needed for transmission, and the MS needs to receive the SYSINFO-DA PDU before it can use a DA cell (see clause 23.7.2), so the MS may prefer to receive the SYSINFO-DA PDU on a likely DA cell before confirming its decision to use that cell. The MLE instructs the MAC to attempt to receive the SYSINFO-DA PDU on a DA adjacent cell by using the TMC-CELL-READ request primitive; see clause 23.7.5.4.

Scanning shall be performed on one RF channel at a time. Three different methods of scanning are defined:

- foreground, where scanning is the only activity;
- background, where communications with the current serving cell are maintained in parallel with the scanning, and the scanning causes no interruption to that service;
- interrupting, where communications with the current serving cell are maintained in parallel with the scanning, but the scanning causes limited interruptions to that service.

### 23.7.5.2.1 Foreground scanning

Foreground scanning is used when the MS is in idle mode on the serving cell and wishes to scan an adjacent cell. The MS switches from the serving cell main carrier to the adjacent cell main carrier. The MS then acquires synchronization and makes the adjacent cell measurements before returning to the serving cell main carrier.

The MS MAC shall carry out the following in response to an MLE instruction to perform foreground scanning:

- Change frequency to the RF channel to be scanned in the adjacent cell.
- Attempt to acquire synchronization on the RF channel to be scanned and:
  - for a CA adjacent cell, decode the cell selection parameters in BNCH; if the BNCH cannot be decoded within 5 s, the scanning shall be stopped;
  - for a DA adjacent cell, decode the cell selection parameters in BSCH-Q; if the BSCH-Q cannot be decoded within 5 s, the scanning shall be stopped.
- Measure the received RF signal strength or equivalent received signal quality. These measurements shall be used for calculating C1. The averaging shall be calculated using at least 5 measurement samples, each sample having a duration of at least SD2 (as defined in clause 10). As far as possible, these samples should be evenly spread over at least 300 ms.
- Calculate C1 for the scanned RF channel.
- Return to the serving cell main carrier.

The MAC may decode the cell selection parameters at the same time as making the RSSI or equivalent measurements. Any measurements made within the 5 s before the start of scanning may also be used to calculate C1.

In the case where the BS is operating in timesharing mode on a CA cell, the measurements shall be made during the timeslots exclusively reserved to the scanned channel and the number of periods may be reduced to the number of active timeslots over a period of two multiframe.

### 23.7.5.2.2 Background scanning

Background scanning is used when the MS wishes to scan an adjacent cell and maintain any current service on the serving cell, whether that is receiving the downlink control channel or transmitting or receiving as part of a call. The MS switches from the serving cell carrier to the adjacent cell main carrier in between any transmissions or receptions on the serving cell. The MS attempts to acquire synchronization on the adjacent cell during those times.

**NOTE:** It is possible that the MLE may request scanning of a channel that the MAC is currently receiving, for example, if a CA MS is currently receiving an assigned channel on a DA main carrier, or if a DA MS is currently receiving an assigned channel on the (if any) local CA main carrier.

The signal strength measurements shall be identical to those performed during monitoring (see clause 23.7.4.3).

When scanning a CA adjacent cell, the MAC shall attempt to synchronize and read the BSCH and BNCH for the scanned RF channel. The MAC shall devote all its monitoring capability to these operations. The parameters decoded on the BNCH shall be used to calculate the path loss parameter C1.

When scanning a DA adjacent cell, the MAC shall attempt to synchronize and read the BSCH-Q for the scanned RF channel. The MAC shall devote all its monitoring capability to these operations. The parameters decoded on the BSCH-Q shall be used to calculate the path loss parameter C1.

The MAC shall keep the information concerning the time synchronization for the RF channels of the list. This information may be used to schedule the subsequent decoding of cell selection parameters and shall be used when accessing a re-selected cell.

When a new RF channel for which the MAC does not have synchronization has to be scanned, the MAC shall devote all its monitoring capability to synchronize on this RF channel and read the cell selection parameters contained in the BNCH (for a CA cell) or BSCH-Q (for a DA cell), in priority over signal strength measurements on all other RF channels. If the cell selection parameters cannot be read within 15 s, a re-attempt shall not take place before  $\text{Attempt\_number} \times 15$  s after the end of the last attempt period,  $\text{Attempt\_number}$  being the number of attempts already performed.

The MAC shall attempt to read the cell selection parameters of each of the RF channels of the list at least every minute, to confirm that it is monitoring the same cell and update the value of these parameters. If a change of identity is detected then the RF channel shall be treated as a new RF channel in the list. If the BSCH or BSCH-Q cannot be decoded, a re-attempt shall be made at the next available opportunity.

For initial and subsequent cell selection parameters decoding, if the cell selection parameters cannot be decoded after 5 attempts, its RF channel shall be discarded from the list and any existing signal strength measurements shall be discarded.

The MAC shall re-calculate the parameter C1 at least every 10 s for the RF channels of the list based on the updated measurement done by monitoring (C2).

### 23.7.5.2.3 Interrupting scanning

Interrupting scanning is similar to foreground scanning except that the MS is participating in a call on the serving cell and temporarily suspends service in order to scan an adjacent cell.

**NOTE:** It is possible that the MLE may request scanning of a channel that the MAC is currently receiving, for example, if a CA MS is currently receiving an assigned channel on a DA main carrier, or if a DA MS is currently receiving an assigned channel on the (if any) local CA main carrier.

The signal strength measurements shall be identical to those performed during monitoring (see clause 23.7.4.3).

The MAC shall attempt to synchronize, read the cell selection parameters and calculate the path loss parameter C1 for all RF channels as instructed by the MLE.

The MAC shall devote all its resources to these operations. If the cell selection parameters cannot be read within 5 s for an RF channel, all signal strength measurements on this RF channel shall be discarded.

The MAC shall keep the information concerning the time synchronization for the RF channels. This information may be used to schedule the subsequent decoding of cell selection parameters and when accessing a re-selected cell. Whenever the MAC re-calculates the parameter C2 for one of these RF channels, it shall re-calculate the parameter C1 for this RF channel. The MAC may periodically attempt to read the cell selection parameters for these RF channels, to confirm that it is monitoring the same cells and update the value of these parameters.

In the case where the radio link is relinquished before the link is declared relinquishable, the MAC shall first check all RF channels for which it has kept the time synchronization according to the indication given by the MLE. If none of the RF channels meets this criterion, the MAC shall perform the cell selection parameters measurement as for unprepared cell selection.

### 23.7.5.3 Scanning with assessment of channel classes on adjacent cell

When the MLE initiates the scanning procedure in the MAC, it may also request assessment of the path loss (C5) for a number of channel classes on that adjacent cell.

Figure 23.22 illustrates how the MLE initiates the scanning procedure with assessment of channel classes on the adjacent cell. The MLE sends a TMC-SCAN request primitive along with a channel number which corresponds to the frequency of the adjacent cell main carrier to be scanned, the modulation mode and RF bandwidth of the adjacent cell main carrier to be scanned, a scanning measurement method to indicate whether foreground, background or interrupted scanning is to be used, and a list of channel classes to be assessed (together with the characteristics of each channel class to be assessed).

**NOTE:** The characteristics of each channel class to be assessed include the modulation mode for that channel class, the maximum MS transmit power for that channel class, the minimum RX access level for that channel class and the BS transmit power relative to the main carrier of the adjacent cell.

The MAC shall make the measurements needed to calculate C1 for the adjacent cell (as defined in clause 23.7.5.2), and shall estimate the path loss (C5) for each of the channel classes to be assessed - based on the RSSI or equivalent measurements made on the scanned main carrier. The MAC shall then pass the C1 result and the C5 results to the MLE using TMC-SCAN confirm primitive. The MS shall use the cell selection parameters broadcast on the adjacent cell for the C1 calculation. The MAC shall use the values of the channel class characteristics parameters provided by the MLE for the C5 calculation (received on the serving cell by the MLE in the D-NWRK-BROADCAST-EXTENSION or D-NWRK-BROADCAST-DA PDU).

**Figure 23.22: Scanning scenario for CA adjacent cell with assessment of channel classes**

**Figure 23.23: Scanning scenario for DA adjacent cell with assessment of channel classes**

#### 23.7.5.4 Reading SYSINFO-DA PDU on DA adjacent cell

When scanning a DA cell, the MS is only required to receive the SYNC-DA PDU; see clause 23.7.5.2. However the MS needs to receive the SYSINFO-DA PDU before it can use a DA cell. Therefore the MS may prefer to receive the SYSINFO-DA PDU on a likely DA cell before confirming its decision to use that cell.

Figure 23.24 illustrates how the MLE instructs the MAC to attempt to receive the SYSINFO-DA PDU on a DA adjacent cell by sending the TMC-CELL-READ request primitive along with a channel number which corresponds to the frequency of the DA adjacent cell main carrier (and the RF bandwidth of the DA adjacent cell main carrier).

The MAC shall attempt to receive the SYSINFO-DA PDU on the specified DA adjacent cell main carrier and shall pass the result to the MLE using the TMC-CELL-READ confirm primitive. If the MAC receives the SYSINFO-DA PDU on the adjacent cell, it shall store the broadcast parameters from the PDU; it shall also pass the TM-SDU and other appropriate parameters to the MLE e.g. using the TMB-SYSINFO-DA indication primitive (see clause 23.6.1.3).

**NOTE:** The MAC needs to refer to information from the SYNC-DA PDU received when scanning that DA adjacent cell e.g. in order to obtain the synchronization of the DA adjacent cell main carrier and the scrambling code to be used for reception of the SYSINFO-DA PDU.

**Figure 23.24: Scenario for reading SYSINFO-DA PDU on DA adjacent cell**

#### 23.7.6 Selection of energy economy mode

An MS may enter energy economy mode by negotiating with the BS. This negotiation shall be performed by an MM message exchange (see clause 16.7.1). Once MM has negotiated a particular energy economy group, the MAC shall be informed through the protocol stack using MLE-INFO request, TL-CONFIGURE request and TMC-CONFIGURE request primitives. These primitives shall include two parameters:

- "Energy economy group"; and
- "Energy economy start point".

"Energy economy group" shall specify how long the MS may sleep between receiving downlink slots on the control channel and shall have one of the values shown in table 23.9. "Energy economy start point" shall specify the frame and multiframe number at which energy economy operation shall begin.

**Table 23.9: Definition of the Economy Groups and duration**

| Economy Group | TDMA frames to sleep |
|---------------|----------------------|
| EG1           | 1                    |
| EG2           | 2                    |
| EG3           | 5                    |
| EG4           | 8                    |
| EG5           | 17                   |
| EG6           | 71                   |
| EG7           | 359                  |

An MS shall only request to enter energy economy mode while on its common control channel. A CA MS's common control channel is the MCCH or a  $\pi/4$ -DQPSK common SCCH. A DA MS's common control channel is the MCCH-Q or a QAM common SCCH.

If the common control channel is a single-slot channel (i.e. the MCCH or a single-slot MCCH-Q or a common SCCH), the MS shall attempt to receive and decode the relevant slot on the main carrier in all the TDMA frames up until and including the frame and multiframe given by the "Energy economy start point". The MS may then sleep for the number of TDMA frames indicated by the "Energy economy group". After this number of TDMA frames has elapsed, the MS shall then attempt to receive and decode the relevant downlink slot in the next TDMA frame. This operation (i.e. the regular cycle of sleeping for N TDMA frames and then receiving the relevant downlink slot in one TDMA frame) shall continue while the MS remains in energy economy mode using this energy economy group.

If the common control channel is a multi-slot MCCH-Q, there are two possible methods:

- a) If the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is available then, when in the sleeping cycle, the DA MS is only required to receive one downlink slot in the reception TDMA frames. That slot is derived from the parameter MS\_SCCH which the MS received on registration or subscription (also used to indicate to the MS which one of the downlink slots on the main carrier shall be used when common SCCHs are in operation). If an MS has received this value at subscription and then also is assigned a value at registration, the value given at registration shall be used. The following rule shall then be applied by the MS to derive its reception slot when in the sleeping cycle:

Reception slot on multi-slot MCCH-Q when in sleeping cycle:

$$= 1 + (\text{MS\_SCCH mod (Number of slots comprising the MCCH-Q)})$$

If the MS does not have a value of MS\_SCCH on this network, and has no value from subscription, it shall assume that its required reception slot on a multi-slot MCCH-Q when in the sleeping cycle is slot 1.

- b) If the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is not available then, when in the sleeping cycle, the DA MS is required to receive all slots comprising the multi-slot MCCH-Q in the reception TDMA frames.

NOTE 1: If the MS does not support enhanced energy economy (or does not wish to use enhanced energy economy) then, even if the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is available, the MS when in the sleeping cycle receives all slots comprising the multi-slot MCCH-Q in the reception TDMA frames. The MS indicates whether it may use enhanced energy economy (if permitted by the BS) using the "part-time reception" sub-element in the "extended capabilities" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

For either method on a multi-slot MCCH-Q, the MS shall attempt to receive and decode all downlink slots comprising the multi-slot MCCH-Q in all the TDMA frames up until and including the frame and multiframe given by the "Energy economy start point". The MS may then sleep for the number of TDMA frames indicated by the "Energy economy group". After this number of TDMA frames has elapsed the MS shall perform the appropriate procedure as follows:

- a) If enhanced energy economy is available, the MS shall attempt to receive and decode the relevant downlink slot (as specified above) in the next TDMA frame. This operation (i.e. the regular cycle of sleeping for N TDMA frames and then receiving the relevant downlink slot in one TDMA frame) shall continue while the MS remains in energy economy mode using this energy economy group.
- b) If enhanced energy economy is not available (or the MS is not using enhanced energy economy), the MS shall attempt to receive and decode all downlink slots comprising the multi-slot MCCH-Q in the next TDMA frame. This operation (i.e. the regular cycle of sleeping for N TDMA frames and then receiving all downlink slots comprising the multi-slot MCCH-Q in one TDMA frame) shall continue while the MS remains in energy economy mode using this energy economy group.

An energy economy mode shall be valid in all cells within a Registered Area (RA). If an MS changes cell within the RA, it may maintain the same energy economy mode and follow the same energy economy pattern after acquiring slot and frame synchronization on the new cell (but using the frame and multiframe numbering of the new cell). All energy economy groups have a cyclic energy economy pattern within a hyperframe and so, given a start point and energy economy group, the MS may calculate the absolute frame and multiframe numbers in which it shall attempt to receive and decode the relevant downlink slot (or relevant downlink slots if appropriate for a multi-slot MCCH-Q). Therefore, even although adjacent cells need not be synchronized, an MS may apply the same energy economy pattern on the new cell within the RA.

NOTE 2: At the time of the cell change, the MS may need to sleep for a shorter time if there is a different synchronization on the new cell. The MS then reverts to the negotiated cycle.

During energy economy mode, the MAC shall temporarily suspend the sleeping cycle if:

- it obeys a channel allocation command allocating an assigned channel; or
- the MS becomes active in an advanced link (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive; or
- the MS becomes active in a call (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive; or
- the MS has signalling messages to send; or
- it receives a TMA-SAP signalling message from the BS for any of its valid addresses or event labels, other than the predefined broadcast group address (all ones).

NOTE 3: If the MS is using enhanced energy economy operation on a multi-slot MCCH-Q, and then needs to suspend the sleeping cycle on the multi-slot MCCH-Q, the MS also reverts to multi-slot reception i.e. attempting to receive and decode all downlink slots comprising the multi-slot MCCH-Q.

However, if the MS suspends the sleeping cycle as the result of receiving a downlink signalling message from the BS, and the next immediate downlink slot is part of the MCCH-Q, the MS is not required to receive that next immediate downlink slot.

The MAC shall return to the sleeping cycle when it is on its common control channel and a time T.210 has elapsed since:

- the higher layers indicated no activity using the TMC-CONFIGURE request primitive; or
- it sent its last signalling message; or
- it last received a TMA-SAP signalling message from the BS for one of its valid addresses or event labels, other than the predefined broadcast group address (all ones),

whichever is the most recent. During this time-out period, the MS shall continue to receive the downlink MCCH or common SCCH slot or MCCH-Q slots for any further signalling from the BS.

NOTE 4: The MS may sleep only on its common control channel, not on an assigned channel.

An MS shall end energy economy mode via an exchange of MM messages with the BS. MM instructs the MAC via the MLE-INFO, TL-CONFIGURE and TMC-CONFIGURE request primitives and the "Energy economy group" set to "Stay alive" to return to receiving the common control channel during all TDMA frames. The MAC shall begin this immediately and so the "Energy economy start point" parameter shall have no meaning in this case.

An MS in energy economy mode may request to change its energy economy group via an exchange of MM messages with the BS. From the perception of the MAC, this function is seen only as receiving an instruction from MM to end energy economy mode and then receiving another instruction to enter energy economy mode.

NOTE 5: Thus, as defined for ending energy economy mode, the MAC obeys the instruction to "Stay alive" immediately so the "Energy economy start point" parameter has no meaning in this case. On receiving the instruction to enter energy economy mode, the MS continues to receive the control channel in all TDMA frames up until and including the frame and multiframe given by the new "Energy economy start point". The MS may then sleep for the number of TDMA frames indicated by the new "Energy economy group". After this number of TDMA frames has elapsed, the MS then receives and decodes the relevant downlink slot (or slots) in the next TDMA frame. Operation with the new sleeping cycle (i.e. the regular cycle of sleeping for N' TDMA frames and then receiving in one TDMA frame) continues while the MS remains in energy economy mode using this energy economy group.

If the MS is in energy economy mode and the MAC receives an instruction from MM to enter energy economy mode then it shall attempt to receive and decode the relevant slot (or slots) on the main carrier in all TDMA frames up until and including the frame and multiframe given by the new "Energy economy start point". It shall then use the sleeping cycle defined by the new "Energy economy group".

NOTE 6: This case may occur if the BS changes the MS's energy economy parameters.

The MS shall end energy economy mode if it leaves the RA (or if it is required to re-register when it moves between a DA cell and a CA cell irrespective of LA).

### 23.7.7 Selection of dual watch mode with energy economy group

An MS may enter dual watch mode by negotiating with the BS. This negotiation is performed by an MM message exchange (see clause 16.7.2). The procedures in this clause relate to dual watch mode when the MS is using an energy economy group.

NOTE 1: A full dual watch MS is capable of periodically receiving the V+D common control channel while it is in a Direct Mode call (when practicable). It is also capable of periodically receiving the Direct Mode RF carrier while it is in a V+D call and, when idle, it periodically receives both the Direct Mode RF carrier and the V+D common control channel. In order for the MS to periodically receive the V+D common control channel while in a Direct Mode call, the MS needs to request to use an appropriate energy economy group when it requests to perform the full dual watching procedure.

An MS may, alternatively, request to perform an idle dual watching procedure in which the MS may not be capable of receiving the V+D common control channel while it is in a Direct Mode call and may not be capable of receiving the Direct Mode RF carrier while it is in a V+D call. It is optional for the MS to request to use an energy economy group when it is performing the idle dual watching procedure.

The procedures defined in this clause relate to the full dual watching procedure. They apply also to the idle dual watching procedure in the case that the MS is using an energy economy group.

Once MM has negotiated dual watch mode with a particular energy economy group, the MAC shall be informed through the protocol stack using MLE-INFO request, TL-CONFIGURE request and TMC-CONFIGURE request primitives. These primitives shall include two parameters:

- "Dual watch energy economy group"; and
- "Dual watch start point".

"Dual watch energy economy group" shall specify how long the MS may be unreachable (transmitting and/or receiving in Direct Mode, and/or sleeping) between receiving downlink slots on the V+D control channel and shall have one of the values shown in table 23.9. "Dual watch start point" shall specify the V+D frame and multiframe number at which dual watch mode using the agreed energy economy group shall begin.

An MS shall only request to enter dual watch mode while on its common control channel. A CA MS's common control channel is the MCCH or a  $\pi/4$ -DQPSK common SCCH. A DA MS's common control channel is the MCCH-Q or a QAM common SCCH.

If the common control channel is a single-slot channel (i.e. the MCCH or a single-slot MCCH-Q or a common SCCH), the MS shall attempt to receive and decode the relevant slot on the main carrier if practicable (i.e. unless Direct Mode requirements take precedence), in all the TDMA frames up until and including the frame and multiframe given by the "Dual watch start point". The MS may then be unreachable (transmitting and/or receiving in Direct Mode, and/or sleeping) for the number of TDMA frames indicated by the "Dual watch energy economy group". After this number of TDMA frames has elapsed, the MS shall then attempt to receive and decode the relevant downlink slot in the next V+D TDMA frame if practicable. This operation (i.e. the regular cycle of being unreachable for N TDMA frames and then receiving the relevant downlink slot in one V+D TDMA frame when practicable) shall continue while the MS remains in dual watch mode using this energy economy group.

If the common control channel is a multi-slot MCCH-Q, there are two possible methods:

- a) If the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is available then, when in the dual watch reception cycle, the DA MS is only required to receive one downlink slot in the reception TDMA frames (when practicable). That slot is derived from the parameter MS\_SCCH which the MS received on registration or subscription (or when it negotiated dual watch). (The parameter MS\_SCCH is also used to indicate to the MS which one of the downlink slots on the main carrier shall be used when common SCCHs are in operation.) If an MS has received this value at subscription and then also is assigned a value at registration (or dual watch negotiation), the value given at registration (or dual watch negotiation) shall be used. The following rule shall then be applied by the MS to derive its reception slot when in the dual watch reception cycle:

Reception slot on multi-slot MCCH-Q when in dual watch reception cycle

$$= 1 + (\text{MS\_SCCH mod (Number of slots comprising the MCCH-Q)})$$

If the MS does not have a value of MS\_SCCH on this network, and has no value from subscription, it shall assume that its required reception slot (when practicable) on a multi-slot MCCH-Q when in the dual watch reception cycle is slot 1.

- b) If the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is not available then, when in the dual watch reception cycle, the DA MS is required to receive all slots comprising the multi-slot MCCH-Q in the reception TDMA frames when practicable.

NOTE 2: If the MS does not support enhanced energy economy (or does not wish to use enhanced energy economy) then, even if the BS indicates in the SYSINFO-DA PDU that enhanced energy economy is available, the MS when in the dual watch reception cycle receives all slots comprising the multi-slot MCCH-Q in the reception TDMA frames when practicable. The MS indicates whether it may use enhanced energy economy (if permitted by the BS) using the "part-time reception" sub-element in the "extended capabilities" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

For either method on a multi-slot MCCH-Q, the MS shall attempt to receive and decode all downlink slots comprising the multi-slot MCCH-Q if practicable, in all the TDMA frames up until and including the frame and multiframe given by the "Dual watch start point". The MS may then be unreachable for the number of TDMA frames indicated by the "Dual watch energy economy group". After this number of TDMA frames has elapsed the MS shall perform the appropriate procedure as follows:

- a) If enhanced energy economy is available, the MS shall attempt to receive and decode the relevant downlink slot (as specified above) in the next V+D TDMA frame if practicable. This operation (i.e. the regular cycle of being unreachable for N TDMA frames and then receiving the relevant downlink slot in one V+D TDMA frame when practicable) shall continue while the MS remains in dual watch mode using this energy economy group.
- b) If enhanced energy economy is not available (or the MS is not using enhanced energy economy), the MS shall attempt to receive and decode all downlink slots comprising the multi-slot MCCH-Q in the next V+D TDMA frame if practicable. This operation (i.e. the regular cycle of being unreachable for N TDMA frames and then receiving all downlink slots comprising the multi-slot MCCH-Q in one V+D TDMA frame when practicable) shall continue while the MS remains in dual watch mode using this energy economy group.

NOTE 3: For both single-slot and multi-slot common control channels, the MS is required to attempt to receive and decode the V+D downlink slots defined in this clause only when practicable i.e. when Direct Mode requirements do not take precedence. When a full dual watching MS is a calling or called party in a Direct Mode call, Direct Mode requirements sometimes take precedence over V+D dual watch requirements (see ETSI EN 300 396-3 [22], clause 8.4.7.10). When an idle dual watching MS is a calling or called party in a Direct Mode call, the MS may not be capable of receiving the V+D control channel for the duration of the Direct Mode call. Even when a dual watching MS is not in a Direct Mode call, if the V+D common control channel is a multi-slot MCCH-Q and the BS does not support enhanced energy economy, in some cases the MS may not be able to receive all slots comprising the MCCH-Q if it needs to maintain its Direct Mode surveillance.

Therefore the BS should be aware that a dual watching MS will not always be able to receive in the agreed slots. (This applies also in the case of an MS that is performing idle dual watch without an energy economy group.)

This may apply for all V+D common control channels. However, in particular, if the V+D common control channel is a multi-slot MCCH-Q and the BS does not support enhanced energy economy, there may be many cases when the MS may not be able to receive all slots comprising the MCCH-Q.

Also the BS should be aware that, even if the MS receives a V+D message, it may not always be able to send a response - even a layer 2 acknowledgement e.g. if the MS is currently in an emergency Direct Mode call or if the MS is in a non-emergency Direct Mode call and the BS does not grant a subslot or slot(s) on the current V+D channel. The BS should also be aware that, if it grants a subslot or slot(s) on the current V+D channel, the MS may sometimes need to use the first granted subslot for linearization (see clause 23.4.5). For a subslot or single-slot grant the MS should then send a response in the next granted subslot or slot (if this occurs within 4 multiframes). For a grant of more than one slot, the MS sends a response in the second granted slot.

Dual watch mode shall be valid in all cells within an RA. If an MS changes cell within the RA, it may maintain the same dual watch energy economy group and follow the same reception pattern after acquiring slot and frame synchronization on the new cell (but using the frame and multiframe numbering of the new cell). All energy economy groups have a cyclic reception pattern within a hyperframe and so, given a start point and energy economy group, the MS may calculate the absolute frame and multiframe numbers in which it shall attempt to receive and decode the relevant downlink slot when practicable (or relevant downlink slots if appropriate for a multi-slot MCCH-Q). Therefore, even although adjacent cells need not be synchronized, an MS may apply the same reception pattern on the new cell within the RA.

NOTE 4: At the time of the cell change, the MS may need to be unreachable for a shorter time if there is a different synchronization on the new cell. The MS then reverts to the negotiated reception cycle.

A dual watching MS shall temporarily revert to receiving the V+D channel in all TDMA frames if:

- it obeys a channel allocation command allocating an assigned channel; or
- it becomes active in a V+D advanced link (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive; or
- it becomes active in a V+D call (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive.

NOTE 5: While on an assigned channel, or when active in a V+D advanced link or call, a full dual watching MS should still periodically receive the Direct Mode RF carrier if practicable, in order to look for calls addressed to itself. However, this may not always be practicable e.g. for a three-slot or four-slot V+D call or for the transmitting party in a circuit mode V+D call if the BS has assigned monitoring pattern 11<sub>2</sub> (i.e. three monitoring patterns).

While on an assigned channel, or when active in a V+D advanced link or call, an idle dual watching MS need not attempt to receive the Direct Mode RF carrier.

If practicable (i.e. unless Direct Mode requirements take precedence), a dual watching MS shall temporarily revert to receiving the V+D channel in all TDMA frames if:

- it has V+D signalling messages to send; or
- it receives a TMA-SAP signalling message from the BS for any of its valid addresses or event labels, other than the predefined broadcast group address (all ones).

NOTE 6: When the MS is in a Direct Mode call, it need not revert to receiving the V+D channel in all TDMA frames when it has V+D signalling messages to send or has received a signalling message from the BS (see ETSI EN 300 396-3 [22], clause 8.4.7.10).

NOTE 7: If the MS is using dual watch with enhanced energy economy operation on a multi-slot MCCH-Q, and then reverts to receiving the V+D channel in all TDMA frames (when practicable), the MS also reverts to multi-slot reception i.e. attempting to receive and decode all downlink slots comprising the multi-slot MCCH-Q (when practicable).

However, if the MS reverts to receiving the V+D channel in all TDMA frames as the result of receiving a downlink signalling message from the BS, and the next immediate downlink slot is part of the MCCH-Q, the MS is not required to receive that next immediate downlink slot.

The MS shall return to the dual watch reception cycle when it is on its common control channel and a time T.220 has elapsed since:

- the higher layers indicated no V+D activity using the TMC-CONFIGURE request primitive; or
- it sent its last V+D signalling message; or
- it last received a TMA-SAP signalling message from the BS for one of its valid addresses or event labels, other than the predefined broadcast group address (all ones),

whichever is the most recent. During this time-out period, the MS shall continue to receive the downlink MCCH or common SCCH slot or MCCH-Q slots in all TDMA frames if practicable (i.e. unless Direct Mode requirements take precedence), for any further signalling from the BS.

NOTE 8: The BS should be aware that it will not always be practicable for the MS to receive the V+D channel in all TDMA frames during the T.220 time-out period e.g. if the MS is currently in a Direct Mode call or if the MS user decides to initiate or receive a Direct Mode call.

NOTE 9: The dual watch reception cycle applies only on the MS's common control channel, not on an assigned channel.

An MS ends dual watch mode via an exchange of MM messages with the BS. MM instructs the MAC via the MLE-INFO, TL-CONFIGURE and TMC-CONFIGURE request primitives and the "Dual watch energy economy group" set to "Stay alive" to return to receiving the common control channel during all TDMA frames. The MAC shall begin this immediately and so the "Dual watch start point" parameter shall have no meaning in this case.

An MS in dual watch mode may request to change its energy economy group via an exchange of MM messages with the BS. From the perception of the MAC, this function is seen only as receiving an instruction from MM to "Stay alive" and then receiving another instruction to enter dual watch mode with the specified energy economy group.

If the MS is in dual watch mode and the MAC receives an instruction from MM to enter dual watch mode with a specified energy economy group then it shall attempt to receive and decode the relevant slot (or slots) on the main carrier if practicable (i.e. unless Direct Mode requirements take precedence), in all TDMA frames up until and including the frame and multiframe given by the new "Dual watch start point". It shall then use the reception cycle defined by the new "Dual watch energy economy group".

NOTE 10: This case may occur if the BS changes the MS's dual watch energy economy group.

The MS cannot operate in both normal energy economy mode and dual watch mode at one time. An MS in energy economy mode may request to change to dual watch mode via an exchange of MM messages with the BS. Conversely, an MS in dual watch mode may request to change to energy economy mode via an exchange of MM messages with the BS. From the perception of the MAC, this function is seen only as receiving an instruction from MM to "Stay alive" and then receiving another instruction to enter the other mode with the specified energy economy group.

The MS shall end dual watch mode if it leaves the RA (or if it is required to re-register when it moves between a DA cell and a CA cell irrespective of LA).

### 23.7.8 Part-time reception for DA MS on multi-slot MCCH-Q

As described in clause 23.7.6, the MS may use energy economy mode when on its common control channel if it has negotiated an energy economy group by an MM message exchange.

The part-time reception procedure is an alternative procedure which may apply when a DA MS is on a multi-slot MCCH-Q. If part-time reception is permitted by the BS, this allows DA MSs in common mode on a multi-slot MCCH-Q to receive and decode just one downlink slot per TDMA frame when they have not sent or received a message recently (based on inactivity timer T.234). When an MS is active on the multi-slot MCCH-Q, it reverts to multi-slot operation.

The part-time reception procedure may provide DA MSs in common mode on a multi-slot MCCH-Q with some opportunities for battery economy, neighbour cell monitoring, irregular channel monitoring and/or background scanning. However it generally requires more reception than when the MS is using energy economy mode.

The BS indicates whether part-time reception by DA MSs on a multi-slot MCCH-Q is permitted using the "part-time reception" element in the SYSINFO-DA PDU.

NOTE 1: MS support of part-time reception on a multi-slot MCCH-Q is indicated in the "extended capabilities" element in the U-LOCATION UPDATE DEMAND PDU; see clause 16.

If the BS indicates in the SYSINFO-DA PDU that part-time reception on a multi-slot MCCH-Q is permitted then, when using part-time reception, the DA MS is only required to receive one downlink slot per TDMA frame. That slot is derived from the parameter MS\_SCCH which the MS received on registration or subscription (also used to indicate to the MS which one of the downlink slots on the main carrier shall be used when common SCCHs are in operation). If an MS has received this value at subscription and then also is assigned a value at registration, the value given at registration shall be used. The following rule shall then be applied by the MS to derive its reception slot when using part-time reception:

$$\begin{aligned} &\text{Reception slot on multi-slot MCCH-Q when using part-time reception} \\ &= 1 + (\text{MS\_SCCH mod (Number of slots comprising the MCCH-Q)}) \end{aligned}$$

If the MS does not have a value of MS\_SCCH on this network, and has no value from subscription, it shall assume that its required reception slot on a multi-slot MCCH-Q when using part-time reception is slot 1.

The MAC shall temporarily suspend part-time reception if:

- it obeys a channel allocation command allocating an assigned channel; or
- the MS becomes active in an advanced link (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive; or
- the MS becomes active in a call (see clause 18.3.5.3.3), as indicated by the MLE activity indicator parameter in the TMC-CONFIGURE request primitive; or
- the MS has signalling messages to send; or
- it receives a TMA-SAP signalling message from the BS for any of its valid addresses or event labels, other than the predefined broadcast group address (all ones).

NOTE 2: If the MS needs to suspend part-time reception while on a multi-slot MCCH-Q, it reverts to multi-slot reception i.e. attempting to receive and decode all downlink slots comprising the multi-slot MCCH-Q.

However, if the MS suspends part-time reception on a multi-slot MCCH-Q as the result of receiving a downlink signalling message from the BS, and the next immediate downlink slot is part of the MCCH-Q, the MS is not required to receive that next immediate downlink slot.

The MAC may return to part-time reception when it is on the multi-slot MCCH-Q and a time  $T_{234}$  has elapsed since:

- the higher layers indicated no activity using the TMC-CONFIGURE request primitive; or
- it sent its last signalling message; or
- it last received a TMA-SAP signalling message from the BS for one of its valid addresses or event labels, other than the predefined broadcast group address (all ones),

whichever is the most recent. During this time-out period, the MS shall continue to receive all slots of the downlink multi-slot MCCH-Q for any further signalling from the BS.

NOTE 3: The part-time reception procedure applies only when the MS is in common mode on a multi-slot MCCH-Q. It does not apply when the MS is on an assigned channel.

An MS may end part-time reception on a multi-slot MCCH-Q at any time if it wishes. The MS shall end part-time reception on a multi-slot MCCH-Q if the BS indicates in the SYSINFO-DA PDU that part-time reception on a multi-slot MCCH-Q is not permitted; the MS shall then revert to receiving all slots of the downlink multi-slot MCCH-Q (within the constraints of the cell reselection procedures, and linearization and transmission requirements).

## 23.8 PDU transfer for traffic (TMD-SAP)

### 23.8.0 General

Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels.

#### 23.8.1 Introduction

For a message trunked system, a complete circuit mode call generally takes place on one  $\pi/4$ -DQPSK assigned channel. Before any traffic transmission, the BS allocates a traffic usage marker for the call.

For a transmission trunked system, each traffic transmission (i.e. "over") takes place on a  $\pi/4$ -DQPSK assigned channel. Between "overs", the MS is directed to its common control channel or to an assigned SCCH. Before each traffic transmission, the BS allocates a traffic usage marker for use on the assigned channel.

For a quasi-transmission trunked system, each traffic transmission takes place on a  $\pi/4$ -DQPSK assigned channel. At the end of an "over", the MS(s) remain on the assigned channel for a short period (i.e. the channel hang-time). If another traffic transmission for the call is requested within the hang-time then the same channel is used for that traffic transmission. Otherwise, after the hang-time, the BS directs the MS(s) to their common control channel, or to an assigned SCCH, until the next traffic transmission is requested; the BS then assigns a channel for that traffic transmission (either the previous assigned channel or a different channel). Before any traffic transmission on an assigned channel, the BS allocates a traffic usage marker for use on that channel.

The choice between these modes is made by the BS. The MS procedures operate independently of this BS choice.

During a call, ACCH is always available in frame 18. When frames 1 to 17 are not being used for traffic, the fast ACCH is available in frames 1 to 18 (see clause 23.3.1.3). In the case of independent allocation of uplink and downlink, or for an inter-site call, the availability of FACCH at any time may be independent on uplink and downlink.

The usage of both uplink and downlink is indicated, independently, in the ACCESS-ASSIGN PDU on the AACH. A traffic usage marker is used when the corresponding direction is in use for traffic (i.e. TCH or STCH). During FACCH, the uplink is controlled by the access field, and the downlink is marked with the assigned control or common control pre-set usage marker as appropriate.

In traffic mode, on frames 1 to 17, capacity may be stolen from the circuit for signalling purposes, without changing the current mode of operation. Use of normal training sequence 2 (i.e. SF = 1) indicates when stealing has occurred and the MAC header in the first half slot indicates whether the second half slot is also stolen. This mechanism applies to both uplink and downlink.

See clause 19 for the configuration of the lower MAC in signalling and traffic mode. The default mode is signalling mode.

NOTE: The STCH mechanism applies only when the channel is in traffic mode, allowing signalling messages to be sent within an "over", and without waiting for frame 18. For example: U-plane signalling (i.e. user-to-user signalling and/or encryption synchronization) is sent on STCH; Call Control (CC) PDU U-TX CEASED should normally be sent on STCH; and D-TX CEASED may be sent on STCH. C-plane signalling messages unrelated to the call may also be sent on STCH.

Between "overs" on a message trunked (or quasi-transmission) trunked system, the assigned channel will normally return to signalling mode (FACCH). The SCH procedures then apply.

## 23.8.2 Criteria for transmission and reception of traffic

### 23.8.2.0 General

During a circuit mode call:

- a sending MS needs to be instructed when to start sending traffic (and when to stop);
- a receiving MS needs to know when to process any received TCH (and when to stop).

This process shall be performed by CC messages sent by the BS to the appropriate MS(s). The CMCE in the MS shall then instruct the MS-MAC using the TMC-CONFIGURE request primitive. There are also some back-up mechanisms using the ACCESS-ASSIGN PDU.

### 23.8.2.1 Use of TMC-CONFIGURE primitive

For the purposes of the protocol description, it is assumed that the instruction from the CMCE for changing the operating mode in the MS-MAC comprises the following sub-parameters:

- switch U-plane on/off;
- Tx-grant flag;
- simplex/duplex flag;
- type of circuit (i.e. TCH/S, TCH/2,4, TCH/4,8, TCH/7,2);
- interleaving depth N;
- end-to-end encryption flag;
- user device;
- endpoint identifier.

The possible combinations of the first three sub-parameters may be:

- |    |   |  |
|----|---|--|
| a) | Switch U-plane on, Tx-grant, Simplex:     | MS is authorized to transmit TCH;                                |
| b) | Switch U-plane on, Not Tx-grant, Simplex: | MS is authorized to receive TCH;                                 |
| c) | Switch U-plane on, Tx-grant, Duplex:      | MS is authorized to transmit and receive TCH;                    |
| d) | Switch U-plane off:                       | Withdraws previous authorization to transmit and/or receive TCH. |

The upper MAC shall inform the lower MAC of the appropriate type of TCH logical channel for transmission and/or reception, since this affects the coding/decoding method.

For the purposes of the protocol description, it is assumed that the process of the MAC issuing a TMA-UNITDATA indication primitive containing a CC message and then receiving the corresponding TMC-CONFIGURE request primitive is effectively instantaneous except in the case when the MS decides to obey a group addressed channel allocation after a delay.

If the MS decides to obey a group addressed channel allocation after a delay then the CMCE may indicate TCH receive authorization when it accepts the channel allocation. However, the MS-MAC shall not use this authorization if the decision to move to the allocated channel has been delayed by more than a time T.215 (see clause 23.8.2.2). If the decision has been delayed by more than a time T.215 then, after moving to the allocated channel, the MS shall not process received TCH until the "N.213 permission method" criterion applies (see clause 23.8.2.3.2) or until authorization by another CC message.

NOTE 1: In case a) above, the MS continues to receive the downlink in the normal manner (subject to the defined monitoring pattern(s)) and using the procedures in clause 23.5.6.3 for interpretation of the downlink. The downlink may be either in signalling or traffic mode.

NOTE 2: If the MS has independent circuit mode calls in progress on the uplink and downlink of the channel, it should use appropriate means to distinguish between the operating mode instructions from the CMCE.

NOTE 3: The MAC may receive changes to the operating mode for the same call, with consecutive changes both containing the instruction to "Switch U-plane on". For example, this may occur if the next traffic transmission has already been requested so that there is no need to return to signalling mode. The most recent instruction for the call over-writes previous instructions, e.g. case b) after case a) withdraws the TCH transmit authorization and gives TCH receive authorization; case a) after case b) withdraws the TCH receive authorization and gives TCH transmit authorization.

### 23.8.2.2 Timing of change of mode

For a switch to U-plane transmission, the MS shall use the following timings:

- If the downlink slot containing the transmit permission (or the final fragment) contained no channel change and no slot grant, then:
  - if in frames 1 to 17, the MS shall start sending traffic in the corresponding uplink slot in that TDMA frame;
  - if in frame 18, the MS shall start sending traffic in frame 1.

NOTE 1: If the MS with transmit permission has received previous slot grants on the assigned channel then that MS should assume that any granted slots in frames 1 to 17 are withdrawn whereas any granted slots in frame 18 are still valid.

- If the downlink slot containing the transmit permission (or the final fragment) contained a slot grant, either with no channel change or with a grant on the allocated channel, then the MS shall start sending traffic in the next full uplink slot on the assigned channel in frames 1 to 17, following the end of the grant. This rule applies even if the grant exceeds the MS's requirement to send signalling messages. When the MS starts sending traffic, note 1 applies to any previous slot grants on the assigned channel.
- If the downlink slot containing the transmit permission (or the final fragment) contained a channel change and no slot grant on the allocated channel, then:
  - if CLCH(-Q) permission is given then the MS shall start sending traffic in the next uplink slot on the assigned channel in frames 1 to 17; this is the next valid full uplink traffic slot following the slot containing the potential CLCH subslot, even if the MS does not need to use CLCH;
  - if CLCH(-Q) permission is not given, e.g. no change of RF carrier, then the MS shall start sending traffic in the first uplink slot on the allocated channel (as defined in clause 23.5.4.3.1) if that slot is in frames 1 to 17, or else in frame 1.

In the first traffic slot, and if the DATA-IN-BUFFER signal from the LLC indicates that there is a message in the buffer for this channel with the stealing permission parameter set to "steal within time T.214" or "steal immediately", then the MS-MAC shall issue a MAC-READY signal to the LLC offering stolen capacity, e.g. for a layer 2 acknowledgement to the layer 3 transmit permission message.

NOTE 2: For the purposes of the above procedures for timing a switch to U-plane transmission, a "slot grant" refers to a grant with "granting delay"  $\neq 1111_2$ . So the MS should regard a "basic slot granting" element with "granting delay" =  $1111_2$  as not being a slot grant.

For a switch to U-plane reception, with no channel change:

- for a single-slot channel, or for a multi-slot channel in which the next downlink slot is not part of that channel, the MS shall switch to U-plane reception at the end of the downlink slot containing the receive permission;
- for a multi-slot channel, and if the next downlink slot is part of that channel, the MS shall delay the switch to U-plane reception by one timeslot duration.

EXAMPLE 1: For a multi-slot channel comprising timeslots 2, 3 and 4, with a switch instruction in downlink slot 2, the MS assumes SCH for downlink slot 3 and then switches to U-plane reception for downlink slot 4. Whereas, if the switch instruction is in downlink slot 4 then the MS switches to U-plane reception for downlink slot 2 in the next TDMA frame.

For a switch to U-plane reception, with a channel change, the MS shall switch to U-plane mode when it moves to the allocated channel, for reception of the first downlink slot on the allocated channel (as defined in clause 23.5.4.3.1). The MS shall use this procedure for an individually addressed channel allocation or if the MS makes an immediate decision to obey a group addressed channel allocation. Also, the MS may use this procedure when it decides to obey a group addressed channel allocation after a delay, provided that the MS-MAC receives the TMC-CONFIGURE request primitive accepting the channel allocation within a time T.215 after receipt of the channel allocation.

In the case of a group addressed channel allocation, if the MS-MAC receives the TMC-CONFIGURE request primitive accepting the channel allocation more than a time T.215 after receipt of the channel allocation then, after moving to the allocated channel, the MS shall not process received traffic until the "N.213 permission method" criterion applies (see clause 23.8.2.3.2) or until authorization by another CC message.

For a switch out of U-plane transmission:

- for a single-slot channel, or for a multi-slot channel in which the next uplink slot is not part of that channel, the MS shall switch mode immediately, i.e. as soon as the downlink message has been processed;
- for a multi-slot channel, and if the next uplink slot is part of that channel, the MS shall delay the switch by one timeslot duration.

EXAMPLE 2: For a multi-slot channel comprising timeslots 2, 3 and 4, with a switch instruction in downlink slot 3, e.g. in frame 10, the MS continues to transmit TCH or STCH in uplink slot 2 before switching. Whereas, if the switch instruction is in downlink slot 2 then the MS stops U-plane transmission at the end of the coinciding uplink slot 4.

For a switch out of U-plane reception:

- for a single-slot channel, or for a multi-slot channel in which the next downlink slot is not part of that channel, the MS shall switch mode at the end of the downlink slot containing the switch instruction;
- for a multi-slot channel, and if the next downlink slot is part of that channel, the MS shall delay the switch by one timeslot duration.

EXAMPLE 3: For a multi-slot channel comprising timeslots 2, 3 and 4, with a switch instruction in downlink slot 2, the MS assumes TCH or STCH for downlink slot 3 and SCH for downlink slot 4.

NOTE 3: If the BS does not receive an expected layer 2 acknowledgement to a downlink message giving or withdrawing authorization to receive traffic on the downlink, it cannot know whether the MS actually received the message; therefore, it cannot know whether the MS is in signalling or traffic mode for reception. In either case, if the BS wishes to send a re-transmission, it is necessary that the MS is able to interpret the downlink channel correctly. At this time, it is recommended that the BS uses only normal training sequence 2, sending either STCH + STCH or SCH/HD + SCH/HD. Interpretation of these forms by MSs is very similar, provided that the BS uses only "length indication"  $111110_2$  or  $111111_2$  in the last PDU in a first half slot, even if that half slot actually contains SCH/HD.

NOTE 4: After being authorized to receive traffic, the MS may switch to traffic mode almost immediately. If TCH from the source is not ready at this time, the BS should send C-plane STCH + STCH on the downlink, e.g. containing Null PDUs.

NOTE 5: As specified above, the switch out of U-plane mode is almost immediate after the CMCE has received the command from the BS. Therefore, for a circuit mode data call with an interleaving depth of  $N = 4$  or  $8$ , the CMCE in the transmitting MS should ensure that the MS has been able to issue  $N - 1$  slots containing tail bits (zeros) to the lower MAC at the end of the required data transmission (on each allocated slot in the case of a multi-slot channel) before sending the U-TX CEASED PDU to the BS. These tail bits are needed to complete the interleaving of the circuit mode data.

### 23.8.2.3 AACH mechanisms

#### 23.8.2.3.0 General

The following procedures specify criteria for stopping transmitting or receiving traffic. There are also criteria for leaving an assigned traffic channel, based on received ACCESS-ASSIGN PDUs. (See clause 23.5.6 for maintenance of an assigned channel.)

#### 23.8.2.3.1 MS transmitting traffic

The MS shall not transmit traffic unless it has been authorized by a CC message and has a traffic usage marker applicable to the uplink channel (i.e. assigned with element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" =  $10_2$  or  $11_2$ ).

During traffic transmission, the MS shall receive and attempt to decode the downlink assigned channel for at least those frames defined by the monitoring pattern information, within the capabilities of that MS.

After starting to transmit traffic, and if the BS does not allow U-plane DTX (i.e. discontinuous traffic transmission by the MS), then the MS shall transmit traffic (TCH and/or STCH) in frames 1 to 17, in successive slots on the uplink assigned channel, as defined by element "Timeslot Assigned", until any one of the following criteria a), b), c) or d) occurs.

NOTE 1: The "U-plane DTX" element in the SYNC PDU, and in the SYSINFO-DA PDU, indicates whether or not the BS supports discontinuous traffic transmission by the MS.

After starting to transmit traffic, and if the BS allows U-plane DTX, then the MS may transmit traffic (TCH and/or STCH) in frames 1 to 17 on the uplink assigned channel, and shall transmit in at least one traffic slot every  $T.213$  TDMA frames, until any one of the following criteria a), b), c) or d) occurs.

- a) Authorization to transmit traffic is withdrawn (either by an instruction to switch the U-plane off or by a switch from transmit to receive for this call).
- b) If one or more monitoring patterns were assigned, i.e. element "Monitoring Pattern"  $\neq 00_2$ :
  - $N.211$  successive ACCESS-ASSIGN PDUs received in frames 1 to 17 on the downlink assigned channel contain "Header"  $\neq 11_2$  or do not contain the correct uplink traffic usage marker.

If no monitoring pattern was assigned, i.e. element "Monitoring Pattern" =  $00_2$ :

- $N.211$  successive ACCESS-ASSIGN PDUs received in any TDMA frame on the downlink assigned channel contain "Header"  $\neq 11_2$  or do not contain the correct uplink traffic usage marker.

- c) If one or more monitoring patterns were assigned, i.e. element "Monitoring Pattern"  $\neq 00_2$ :

- a time  $T.211$  elapses without receipt of an ACCESS-ASSIGN PDU in frames 1 to 17 on the downlink assigned channel, containing "Header" =  $11_2$  and containing the correct uplink traffic usage marker.

If no monitoring pattern was assigned, i.e. element "Monitoring Pattern" =  $00_2$ :

- a time  $18 \times T.211$  elapses without receipt of an ACCESS-ASSIGN PDU in any TDMA frame on the downlink assigned channel, containing "Header" =  $11_2$  and containing the correct uplink traffic usage marker (as "Field 2" in frames 1 to 17 or "Field 1" in frame 18).

- d) The MS leaves the assigned channel (see clause 23.5.6.1).

NOTE 2: For a multi-slot channel, if the MS is not frequency full duplex, and if the BS assigns monitoring pattern(s) that the MS is not capable of following in any slots in frames 2 to 17, then, in criteria b) and c), the MS should use the method specified for element "Monitoring Pattern" = 00<sub>2</sub>.

In all cases a), b), c) and d), the MS shall stop transmitting traffic (TCH and STCH) and shall revert to the normal C-plane methods of random access and reserved access in all frames 1 to 18.

In cases b) or c), the MS-MAC shall report the change of mode to the higher layers using the TMC-REPORT indication primitive.

In case d), the interruption may be only temporary. If the MS is changing channel on instruction from the BS and if:

- the "Allocation Type" = 00<sub>2</sub> or 11<sub>2</sub> ("Replace" or "Replace + CSS channel"); and
- the MS is being directed to an assigned channel (i.e. element "Timeslot Assigned" ≠ 0000<sub>2</sub>); and
- the uplink is assigned (i.e. element "Up/downlink assigned" or "Up/downlink assigned for augmented channel allocation" = 10<sub>2</sub> or 11<sub>2</sub>); and
- the MS receives a traffic usage marker assignment with the channel allocation; and
- the MS does not receive a CC message withdrawing authorization to transmit traffic; and
- this is an individually addressed channel allocation or, for a group addressed channel allocation, the MS decides within a time T.216 to obey the channel allocation,

then, on receipt of the channel allocation, the MS-MAC shall stop transmitting traffic on the current channel. For a single-slot channel, or for a multi-slot channel in which the next uplink slot is not part of that channel, the MS shall stop transmitting traffic immediately. For a multi-slot channel, and if the next uplink slot is part of that channel, the MS shall delay the switch by one timeslot duration. After changing channel, the MS shall continue traffic transmission as follows:

```

if the MS has a slot grant on the assigned channel
then the MS shall continue traffic transmission in the next uplink slot on the
    assigned channel (in frames 1 to 17), following the end of the slot grant
else
if "Immediate CLCH(Q) permission" is given
    then the MS shall continue traffic transmission in the next full uplink slot on the
        assigned channel (in frames 1 to 17), following the slot containing the potential
        CLCH subslot
    else the MS shall continue traffic transmission in the first uplink slot on the
        allocated channel (as defined in clause 23.5.4.3.1) if that slot is in
        frames 1 to 17 or otherwise in frame 1.

```

This rule shall apply both for allocation within the same cell and for a different cell (seamless handover i.e. type 1 announced cell reselection).

For a channel change that does not conform to the above, or if the MS decides not to move to the allocated channel, the MS-MAC shall stop transmitting traffic and shall report the change of mode to the higher layers.

If, after starting to transmit traffic and at any time other than during a temporary interruption for channel change, the MS receives a slot grant addressed to itself, and granting a reserved uplink subslot or slot(s) in frames 1 to 17 (i.e. where it expected to transmit traffic), then the MS-MAC shall stop transmitting traffic, reporting the change of mode to the higher layers.

NOTE 3: The scenario above should not occur except in case of transmission errors. It is not intended for use by the BS as a normal method for ending U-plane transmission.

NOTE 4: Criterion b) refers to a check on those ACCESS-ASSIGN PDUs that are received by the MS, irrespective of whether or not these are in successive slots on the assigned channel. Then criterion c) covers the case when the ACCESS-ASSIGN PDU is not received during the specified time.

If no monitoring pattern is assigned, the BS should use "Header" 11<sub>2</sub> in ACCESS-ASSIGN PDUs in frame 18 on the downlink assigned channel, including the traffic usage marker of the transmitting MS. This applies also for a multi-slot channel if the BS assigns monitoring pattern(s) that the MS may not be capable of following in any slots in frames 2 to 17.

NOTE 5: The "channel replace" mechanism without withdrawal of transmit authorization may be used within the cell, for convenience of BS resource allocation, or between cells e.g. for seamless handover (type 1 announced cell reselection). Before continuing U-plane transmission, the MS may be required to transmit a C-plane reply, in a reserved slot on either the current or allocated channel, or by stealing.

Alternatively, the BS may prefer to interrupt the traffic transmission by sending the CC PDU D-TX WAIT (temporarily withdrawing transmit permission).

### 23.8.2.3.2 MS receiving traffic

The MS should process received traffic after authorization by a CC message, except that it shall not process received TCH if it does not have a traffic usage marker applicable to the downlink channel (i.e. assigned with element "Up/downlink Assigned" or "Up/downlink assigned for augmented channel allocation" =  $01_2$  or  $11_2$ ). Also, if a group addressed channel allocation was sent with the CC message and the decision to accept the channel allocation was delayed by more than time T.215 then the MS shall not process received TCH on the allocated channel until the "N.213 permission method" criterion applies or until authorization by another CC message.

The MS may process received traffic, without specific authorization, if N.213 ACCESS-ASSIGN PDUs received in frames 1 to 17 in successive slots appropriate to the downlink assigned channel contain Header  $\neq 00_2$  and contain the correct downlink traffic usage marker for this MS. The MS-MAC should report the change of mode to the higher layers using the TMC-REPORT indication primitive.

NOTE 1: If the CMCE indicates traffic receive permission when it accepts a group addressed channel allocation after a delay of more than time T.215 then the MS-MAC is not precluded from reducing its value of N.213 provided that the reduced value of N.213  $\geq 2$ . This applies also for a channel replacement without withdrawal of receive authorization if the MS accepts a group addressed channel allocation after a delay of more than time T.215 (see below). The reduced value of N.213 may apply until the MS next receives a CC message indicating authorization or withdrawal of authorization to transmit or receive traffic on the allocated channel.

The MS shall process any received traffic (TCH and STCH) in frames 1 to 17 in slots on the downlink assigned channel until any one of the following occurs:

- a) authorization to receive traffic is withdrawn (either by an instruction to switch the U-plane off or by a switch from receive to transmit for this call);
- b) N.212 successive ACCESS-ASSIGN PDUs received in frames 1 to 17 on the downlink assigned channel contain "Header" =  $00_2$  or do not contain the correct downlink traffic usage marker;
- c) a time T.212 elapses without receipt of an ACCESS-ASSIGN PDU in frames 1 to 17 on the downlink assigned channel, containing "Header"  $\neq 00_2$  and containing the correct downlink traffic usage marker;
- d) the MS leaves the assigned channel (see clause 23.5.6.1), unless the criteria described below are satisfied.

In all cases, the MS shall stop processing received traffic.

In cases b), c) or d), the MS-MAC shall report the change of mode to the higher layers using the TMC-REPORT indication primitive.

In all cases, the MS may again process received traffic either after authorization by a CC message or by using the "N.213 permission method" described above.

The exception to case d) is that, if the MS changes channel on instruction from the BS and if:

- the "Allocation Type" =  $00_2$  or  $11_2$  ("Replace" or "Replace + CSS channel");
- the MS is being directed to an assigned channel (i.e. element "Timeslot Assigned"  $\neq 0000_2$ );
- the downlink is assigned (i.e. element "Up/downlink Assigned" or "Up/downlink assigned for augmented channel allocation" =  $01_2$  or  $11_2$ );
- the MS receives a traffic usage marker assignment with the channel allocation;
- the MS does not receive a CC message withdrawing authorization to receive traffic; and

- this is an individually addressed channel allocation or, for a group addressed channel allocation, the MS decides within a time T.215 to obey the channel allocation,

then the MS-MAC shall switch out of U-plane reception at the end of the downlink slot containing the channel allocation; or, for a multi-slot channel, and if the next downlink slot is part of that channel and the MS is still on the current channel to receive that slot (see note 2), the MS shall delay the switch by one timeslot duration. The MS shall switch back to U-plane reception when it moves to the allocated channel, using the newly assigned usage marker, for reception of the first downlink slot on the allocated channel (as defined in clause 23.5.4.3.1).

This rule shall apply both for allocation within the same cell and for a different cell.

NOTE 2: For the purposes of this procedure it is assumed that, for a multi-slot channel, and if the next downlink slot is part of that channel, then the MS is "still on the current channel to receive that slot" only in the cases defined in condition b) of procedure 1) in clause 23.5.4.3.1 and, for a frequency full duplex MS, condition c) of procedure 1) in clause 23.5.4.3.1 i.e. in the cases of a channel allocation with a slot grant on the current channel and, for a frequency full duplex MS, if the next immediate uplink slot following the channel allocation is part of the current channel and the MS is transmitting traffic in that slot or was previously granted that slot (or a subslot in that slot) for reserved access. So, for the purposes of this procedure, it is assumed that the MS is not "still on the current channel to receive that slot" if the timing of the channel change is based on condition a) of procedure 1) in clause 23.5.4.3.1.

NOTE 3: Criterion b) refers to a check on those ACCESS-ASSIGN PDUs that are received by the MS, irrespective of whether these are in successive slots on the assigned channel. Whereas the "N.213 permission method" applies only if ACCESS-ASSIGN PDUs are received in successive traffic slots on the assigned channel.

NOTE 4: The permission method based on parameter N.213 should not be used by an MS that is transmitting in simplex mode and that has only one circuit mode call on this channel i.e. the MS should not attempt to transmit and receive simultaneously in a simplex call.

NOTE 5: The "channel replace" mechanism without withdrawal of receive authorization may be used within the cell, for convenience of BS resource allocation, or between cells e.g. for seamless handover (type 1 announced cell reselection).

If an MS that is receiving traffic is sent to a different timeslot during an end-to-end encrypted call, the BS may choose to interrupt the transmitting station with the D-TX WAIT PDU, thereby causing the transmitting station to re-send encryption synchronization when the transmission starts again.

NOTE 6: In the case of circuit mode data, in order to avoid corrupting downlink data transmission, the BS designer may prefer (when possible) to send any channel allocation commands or D-TX WAIT PDUs in frame 18.

NOTE 7: The MS is not permitted to maintain traffic receive authorization if it accepts a group addressed channel allocation after a delay of more than time T.215; after moving to the new channel, it cannot process received TCH until the "N.213 permission method" criterion applies (using the traffic usage marker for the new channel) or until authorization by a CC message.

### 23.8.2.3.3 Multi-slot interleaving with interruption

If a circuit mode data transmission is interrupted, either by use of the CMCE's D-TX WAIT mechanism or by a "channel replace", as defined in the above two clauses, then the MS shall continue with the transmission or reception of the data as if the intervening time out of U-plane mode had not been present. This rule includes the interleaving/de-interleaving of the data for interleaving depth  $N = 4$  or  $8$ .

For a single-slot channel with  $N = 4$  or  $8$ , the MS shall continue to process the U-plane data after the interruption, performing interleaving/de-interleaving of the old data with the new data as traffic blocks are transmitted/received.

For a multi-slot channel with  $N = 4$  or  $8$ , multiple single-slot data TCHs are operated in parallel in order to obtain the multi-slot TCH transmission, as defined in clause 23.3.5. After an interruption, the order of presentation of the data at the receiving side shall be maintained. Therefore, across the interruption, the single-slot TCHs may be linked between different timeslot numbers according to the next occurring traffic slot.

**EXAMPLE:** For a multi-slot channel comprising timeslots 1, 2 and 3, where a slot 1 is the last traffic slot before interruption and a slot 3 is the next traffic slot:

- the old interleaving process corresponding to slot 2 continues in slot 3;
- the old interleaving process corresponding to slot 3 continues in slot 1;
- the old interleaving process corresponding to slot 1 continues in slot 2.

Similarly, for a multi-slot channel comprising timeslots 1, 2 and 3, with a new channel allocation comprising timeslots 1, 3 and 4, where a slot 2 contained the last traffic on the old channel and a slot 3 contains the first traffic on the new channel:

- the old interleaving process corresponding to slot 3 continues in slot 3;
- the old interleaving process corresponding to slot 1 continues in slot 4;
- the old interleaving process corresponding to slot 2 continues in slot 1.

This second example could be caused either by use of the channel replace without withdrawal of U-plane authorization, or by use of the D-TX WAIT mechanism with a channel replacement during the pause.

**NOTE:** The procedures defined in this clause do not apply for a group addressed channel replacement if the MS decides to obey the channel allocation after a delay.

## 23.8.3 Exchange of information at the TMD-SAP

### 23.8.3.0 General

In the protocol model, the actual user traffic is transferred between the U-plane application (e.g. the speech CODEC) and the MS-MAC via the TMD-SAP. The TMD-SAP is used for the transfer of speech frames or circuit mode data. It is also used if the U-plane application steals from the traffic capacity to send U-plane signalling.

For the purposes of the protocol description, the following services primitives are used. However, this does not imply any specific implementation. The word "shall" is used with the primitives and their parameters for traceability reasons in the protocol model, but the primitives are not testable.

- The TMD-UNITDATA request primitive shall be used when the U-plane application wishes to send information to the peer entity.
- The TMD-UNITDATA indication primitive shall be used for the MS-MAC to deliver information from the peer entity.
- The TMD-REPORT indication primitive shall be used by the sending MAC to issue reports to the U-plane application e.g. at the start and stop of traffic transmission, and when the MS changes channel within an "over", and when the MAC has stolen from the traffic capacity. It shall also be used by the receiving MAC at the start of a call.

The parameters specific to the TMD-UNITDATA primitive are as follows (see clause 20):

#### a) Half slot content:

The unit of information in the TMD-UNITDATA primitive is one half slot. The U-plane application shall provide a TM-SDU of the correct size for the appropriate logical channel, so that the MS-MAC does not have to insert filler bits to complete the MAC block nor have to remove filler bits on reception.

In particular, when the U-plane application steals from the traffic capacity for U-plane signalling, the TM-SDU shall always be 121 bits. The upper MAC shall then add a 3-bit MAC header, making the MAC block up to the 124 bits required for STCH. The U-plane signalling may be for user-to-user signalling or for encryption synchronization. However, the MAC is not aware of the intended purpose of the U-plane signalling. (Any necessary discrimination shall be included within the TM-SDU.)

User traffic TCH does not have a MAC header.

## b) Half slot position:

Each transferred half slot (in either direction) should be accompanied by a marker identifying it as the first or second half slot of a timeslot.

At all points in the system, half slots should be grouped in pairs, equivalent to the data transmitted over the air interface in one slot. The binding between these pairs shall remain intact and the correct timing/ordering relationships with adjacent half slots preserved, even when a half slot is stolen and the half slots are processed separately by the MAC.

## c) Stolen indication:

At the transmitting side, this parameter shall indicate whether the half slot is stolen for U-plane signalling or not stolen.

At the receiving side, this parameter shall indicate whether the half slot was stolen for C-plane signalling, stolen for U-plane signalling or not stolen.

## d) Half slot importance:

This parameter may be used only in the TMD-UNITDATA request primitive. It indicates the importance of the U-plane information, enabling the sending MS-MAC to decide when and whether to steal from the traffic capacity and to decide whether to use U-plane DTX (discontinuous traffic transmission). Four levels of importance may be used: no importance, and low, medium and high importance.

## e) Half slot condition:

This parameter may be used only in the TMD-UNITDATA indication primitive. It indicates to the receiving U-plane application whether a half traffic slot was received successfully. It may take the following values:

- "Good" if the half slot was decodeable;
- "Bad" if a valid training sequence was detected but the CRC check failed;
- "Null" if no valid training sequence was detected.

The distinction between "Good" and "Bad" is not appropriate for TCH/7,2.

## f) User device:

The user device parameter shall identify the appropriate circuit.

NOTE 1: For the purposes of the protocol description, channel encoding and decoding are performed in the lower MAC. However, this does not imply any particular implementation. If, for example, the implementers were to choose to perform the channel coding of TCH directly in the CODEC, then the descriptions of half slot transfer generally still apply (though the distinction between "Good" and "Bad" in the "half slot condition" parameter is no longer relevant).

NOTE 2: For the purposes of the protocol description, the unit of exchange at the TMD-SAP is always a half slot (corresponding to one speech frame). However, this does not imply any particular implementation. For example, implementers may prefer to use a full slot of data as the unit of exchange for circuit mode data TCH.

NOTE 3: It is assumed that the U-plane application provides valid data in the "half slot content" parameter even if the "half slot importance" is set to "no importance".

### 23.8.3.1 Interface at transmitting MS

At the start of a call (or before each "over"), or if the basic service information changes, the MS-MAC shall issue a report to the U-plane application to supply the traffic type, the interleaving depth, the number of slots per TDMA frame, a flag indicating whether end-to-end encryption applies and the user device parameter.

When the MS has been authorized to transmit TCH, and has established whether it will steal the first half slot for C-plane signalling (e.g. a layer 2 acknowledgement), the MS-MAC shall issue a report to the U-plane application. This report shall indicate the initial half slot synchronization i.e. whether the first valid U-plane half slot is a first or second half slot; that half slot may then be used either for TCH or for U-plane signalling.

A report should be issued to the U-plane application if there is any interruption (e.g. a channel change) so that, for an end-to-end encrypted call, the U-plane application can send encryption synchronization again.

A report should also be issued to the U-plane application when traffic transmission is no longer permitted.

When transmitting a slot in traffic mode, the sending MS-MAC is generally given the first half slot by the U-plane application, in a TMD-UNITDATA request primitive. That half slot may be either TCH, or U-plane signalling in the case of stealing by the U-plane application.

If the MS-MAC decides to steal the first half slot for C-plane signalling then the MAC should issue a TMD-REPORT indication primitive, enabling the U-plane application to revise the intended use of the second half slot.

The MS-MAC is then given the second half slot in another TMD-UNITDATA request primitive. Again, if the MS-MAC decides to steal the half slot for C-plane signalling then the MAC should issue a TMD-REPORT indication primitive.

In the case of circuit mode data with low or high protection: if the U-plane application steals the first half slot but not the second half slot then it should issue two TMD-UNITDATA request primitives for the first half slot (one containing the U-plane signalling data and the other containing TCH) and one TMD-UNITDATA request primitive for the second half slot (containing TCH). In the case of circuit mode data with interleaving depth  $N = 4$  or  $8$ : if the U-plane application steals both half slots then it should issue two TMD-UNITDATA request primitives for each half slot (one containing the U-plane signalling data and the other containing TCH).

At this time, the MS-MAC has the contents of one slot. Permitted combinations for the two half slots are as follows:

- a) Not stolen i.e. TCH / Not stolen i.e. TCH;
- b) Stolen for C-plane / Not stolen i.e. TCH;
- c) Stolen for U-plane / Not stolen i.e. TCH;
- d) Stolen for C-plane / Stolen for C-plane;
- e) Stolen for C-plane / Stolen for U-plane;
- f) Stolen for U-plane / Stolen for C-plane;
- g) Stolen for U-plane / Stolen for U-plane.

In case a), and if the BS allows U-plane DTX, the MS may decide not to transmit in the slot, based on the "half slot importance" of the two half slots. If the MS transmits in the slot then normal training sequence 1 shall be used, with a full slot of TCH (MAC-TRAFFIC PDU). In all the other cases, normal training sequence 2 shall be used and the stealing procedure described in clause 23.8.4 shall apply.

In cases b) and c), for a speech call or unprotected data, the upper MAC shall issue a half slot of STCH and a half slot of TCH to the lower MAC. In cases d), e), f) and g), for a speech call or unprotected data, the upper MAC shall issue two half slots of STCH to the lower MAC.

In cases b) and c), for a circuit mode data call with low or high protection, the upper MAC shall issue both a half slot of STCH and a full slot of TCH to the lower MAC. In cases d), e), f) and g), for a circuit mode data call with  $N = 1$ , the upper MAC shall issue two half slots of STCH to the lower MAC. In cases d), e), f) and g), for a circuit mode data call with  $N = 4$  or  $8$ , the upper MAC shall issue two half slots of STCH and also a full slot of TCH to the lower MAC.

NOTE 1: Not stolen + Stolen for C-plane is not a permitted combination.

If the MAC receives Not stolen + Stolen for U-plane from the U-plane application, it could use case e), replacing the traffic with a dummy C-plane message (containing no TM-SDU). However, this would make inefficient use of the channel. It is recommended that the U-plane application does not request this form.

NOTE 2: In an implementation, it may be preferred that (when practicable) the MAC informs the U-plane application as soon as it knows that it will perform C-plane stealing. For example, for a high priority C-plane message, the MAC may intend to steal irrespective of the U-plane half slot importance.

NOTE 3: The above procedure specifies that, for protected circuit mode data with stealing in a slot, the upper MAC may issue both the STCH and a full slot of TCH to the lower MAC. This is because, for protected circuit mode data, the lower MAC replaces traffic bits with STCH bits after normal coding and interleaving of the TCH (see clause 8). This contrasts with the method for speech, where the second half slot is half-slot interleaved if the first half slot is stolen.

### 23.8.3.2 Interface at receiving MS

At the start of a call, or if the basic service information changes, the receiving MS-MAC shall issue a report to the U-plane application to supply the traffic type, the interleaving depth, the number of slots per TDMA frame, a flag indicating whether end-to-end encryption applies and the user device parameter.

The following procedures in this clause shall apply for reception in frames 1 to 17 by an MS that is authorized to receive TCH.

TCH shall be passed to the U-plane application.

U-plane signalling shall be passed to the U-plane application after removal of the 3-bit MAC header.

C-plane STCH shall be processed by the MAC, and any suitably addressed TM-SDUs shall be passed to the LLC.

In all cases, for each half slot, the MS-MAC shall issue the TMD-UNITDATA indication primitive to the U-plane application containing any U-plane information (TCH or STCH) and indicating whether the half slot was stolen for C-plane signalling, stolen for U-plane signalling or not stolen.

For protected circuit mode data, in the case of a slot in which only the first half slot was stolen, the upper MAC should receive a half slot of STCH and a full slot of TCH from the lower MAC. The upper MAC shall issue a TMD-UNITDATA indication primitive to the U-plane application containing the U-plane signalling data (if the first half slot was stolen for U-plane signalling) and shall issue two TMD-UNITDATA indication primitives containing TCH, one for each half slot. For circuit mode data with  $N = 4$  or  $8$ , in the case that both half slots are stolen, the upper MAC should receive two half slots of STCH and a full slot of TCH from the lower MAC. The upper MAC shall issue the appropriate TMD-UNITDATA indication primitive(s) to the U-plane application containing U-plane signalling data (if either half slot was stolen for U-plane signalling) and shall issue two TMD-UNITDATA indication primitives containing TCH.

NOTE 1: For the purposes of the protocol description, in the case of U-plane stealing from circuit mode data with  $N = 1$ : when the U-plane signalling data is delivered to the U-plane application, it is associated with the same half slot as the circuit mode data delivered for that half slot. In any instances for which it is necessary to define the relative order of the two types of data associated with a half slot, it is recommended that the U-plane application considers the U-plane signalling data associated with the half slot to be available before the circuit mode data associated with that half slot.

The same principle applies to circuit mode data with  $N = 4$  or  $8$ . However, the  $N - 1$  traffic frame delay procedure for U-plane signalling also applies, as described below.

For the purposes of the protocol description (see note 3): in the case of U-plane stealing from circuit mode data with  $N = 4$  or  $8$ , the receiving upper MAC shall delay the issuing of the TMD-UNITDATA indication primitive(s) containing the U-plane signalling data by  $N - 1$  traffic frames.

NOTE 2: This procedure for delaying the delivery of signalling data for  $N = 4$  and  $8$  applies only to U-plane stealing (not to C-plane stealing).

The procedure is defined so that the U-plane signalling is delivered to the U-plane application with the same U-plane circuit mode data as when it was given by the sending U-plane application to the sending upper MAC. The need for the procedure arises because the multi-slot interleaving causes the circuit mode data to be delayed by  $N - 1$  traffic frames across a link of the air interface, whereas the U-plane signalling is not delayed.

NOTE 3: For the purposes of the protocol description, the U-plane signalling is delayed in the upper MAC. However, in an implementation, it may be preferred that the upper MAC delivers the U-plane signalling to the U-plane application as soon as it is received. In this case, it is a task of the U-plane application to delay position-sensitive signalling (such as end-to-end encryption synchronization) before use.

In the case of un-decodeable TCH, the MS-MAC may pass the received data to the U-plane application, but shall set the "half slot condition" parameter appropriately in the TMD-UNITDATA indication primitive.

## 23.8.4 Stealing from circuit mode capacity

### 23.8.4.1 Uplink stealing

#### 23.8.4.1.1 Transmission on uplink STCH

Transmission on STCH shall only be used by an MS that has been authorized to transmit traffic.

The appropriate PDUs for C-plane STCH on the uplink shall be:

- MAC-DATA PDU: first or second half slot;
- MAC-END PDU: second half slot only (final fragment).

The appropriate PDU for U-plane STCH shall be:

- MAC-U-SIGNAL PDU: first or second half slot.

The MAC header of a MAC-U-SIGNAL PDU sent in a first half slot shall indicate whether the second half slot is also stolen, using the second half slot stolen flag. If the second half slot is stolen, it may contain either U-plane or C-plane signalling (as indicated by the first MAC header in the second half slot).

For C-plane stealing within the first half slot, PDU association may be used. The "Length indication" in the last MAC-DATA PDU, or in the only MAC-DATA PDU, in the first half slot shall indicate whether the second half slot is also stolen.

- i) "Length indication"  $\leq 010000_2$ : second half slot not stolen.

Then the second half slot shall contain TCH (MAC-TRAFFIC PDU).

- ii) "Length indication" =  $111110_2$ : second half slot stolen, no fragmentation.

Then the second half slot may contain either U-plane or C-plane signalling (as indicated by the first MAC header in the second half slot). For C-plane signalling, PDU association may be used within the second half slot.

- iii) "Length indication" =  $111111_2$ : second half slot stolen, start of fragmentation.

Then the final fragment shall be sent in the second half slot (except in case of cancellation), using the MAC-END PDU. If PDU association is used within the second half slot, then the fragment shall be sent as the first PDU in the MAC block.

After transmitting a C-plane TM-SDU, the MS-MAC shall report to the LLC that the message has been sent by stealing (using the TMA-REPORT indication primitive).

#### 23.8.4.1.2 Criteria for uplink stealing

When an MS is authorized to transmit traffic, the MS-MAC may steal from the traffic capacity to send C-plane signalling. The MS then sends C-plane signalling instead of the data received from the U-plane application. The MS-MAC shall not move the replaced U-plane data (neither traffic nor signalling) to a different half slot or slot.

The MS-MAC should report C-plane stealing to the U-plane application, enabling the application to revise the intended use of subsequent half slots, or to retransmit any U-plane signalling that has been overwritten by the MAC.

The following procedures shall apply for the different settings of the stealing permission parameter for the C-plane message.

a) Steal immediately

The MS-MAC shall send the C-plane message at the first opportunity on the uplink assigned channel, without regard to the half slot importance. This rule shall apply to both one- and two-half-slot messages.

For this setting of the stealing permission parameter, and if the MS is authorized to transmit traffic, the MS-MAC shall use stealing in preference to using random access or reserved access on frame 18.

b) Steal within time T.214

If the MS has not been granted a reserved subslot or slot in frame 18 (i.e. in the uplink SACCH for this channel) then the MS-MAC shall send the message within the next T.214 traffic slots on the uplink assigned channel (i.e. within the next T.214 TDMA frames 1 to 17 for a single-slot channel). This rule shall apply to both one- and two-half-slot messages.

The MS-MAC should send the message in the first slot for which the half slot importance is not "high". Or, if this does not occur within T.214 - 1 slots, the MS-MAC shall send the message in the T.214<sup>th</sup> traffic slot on the uplink assigned channel, without regard to the half slot importance.

c) Steal when convenient

The MS designer should choose suitable criteria for deciding when the MS-MAC may steal, based on the priority of the C-plane message, the half slot importance and the time since the last stealing occurrence. It is recommended that the MS-MAC does not re-steal over U-plane signalling.

d) Stealing not required

The MS-MAC should not use stealing to send the message (unless the half slot importance of the traffic is set to "no importance").

The MS designer should note that frequent stealing would degrade the quality of the circuit.

NOTE 1: The stealing permission parameter should be set to "steal immediately" for U-TX CEASED (and U-DISCONNECT if currently transmitting traffic). The stealing permission parameter should be set to "steal within time T.214" for the reply to a BS message received while the MS is transmitting traffic, e.g. for a layer 2 acknowledgement.

NOTE 2: For "steal within time T.214", the MS-MAC may plan when to steal based on the stealing permission parameter in the DATA-IN-BUFFER signal from the LLC. The MAC should not issue the MAC-READY signal until it is actually ready to send the message, thereby allowing the maximum time if the layer 3 in the MS is preparing a response to the BS message.

### 23.8.4.1.3 Stealing repeats mechanism

When the MS-MAC has used stealing to transmit a C-plane PDU with stealing permission parameter = "steal immediately", it shall check the setting of the "stealing repeats flag" in the TMA-UNITDATA request primitive. For a message with stealing permission parameter  $\neq$  "steal immediately", or if this flag is not set, the MS-MAC shall regard the requested procedure as complete and shall discard the TM-SDU, i.e. it shall use the normal procedure.

A special procedure shall apply for a message with "steal immediately" if the stealing repeats flag is set.

Then the MS-MAC shall repeat the message on STCH, sending the message once per frame in successive traffic frames (i.e. frames 1 to 17) on the assigned uplink channel, until either:

- a) it has sent the message N.214 times (including the first transmission); or
- b) it has stopped transmitting traffic, e.g. as a result of a higher layer message or after checks on the ACCESS-ASSIGN PDU; or
- c) it receives a TMA-CANCEL request primitive from the higher layers instructing it to abort transmission of the message.

In cases a) and b), the MS-MAC shall regard the requested procedure as complete and shall discard the TM-SDU. In case c), the MS-MAC shall cease attempting to send the message and shall discard the TM-SDU (see also clause 23.5.3).

While the MS-MAC is performing the "stealing repeats" mechanism described above, it shall over-ride the normal monitoring pattern information, and shall attempt to receive and decode the downlink assigned channel in every TDMA frame. For a multi-slot channel, and if the MS is not frequency full duplex, the MS shall transmit only in the lowest numbered uplink slot appropriate to the assigned channel, sending its message in that slot. It shall attempt to receive and decode at least the lowest numbered downlink slot appropriate to the assigned channel in all frames 1 to 17, and all slots appropriate to the assigned channel in frame 18 (within the constraints of linearization and transmission requirements).

If the MS-MAC stops the requested procedure on criterion a) or c) above then it shall continue to use the modified rules for receiving and decoding the downlink channel for the T.251 TDMA frames following the N.214<sup>th</sup> transmission of the message.

NOTE 1: The stealing repeats flag may be used by the higher layers to trigger this special stealing method in the MAC. This method is intended for signalling at the end of an uplink traffic transmission, for U-TX CEASED or possibly U-DISCONNECT. It provides a faster procedure for signalling the end of traffic transmission in case of propagation errors. Firstly, it allows more frequent repeats of the message. Also, the method of modifying the normal monitoring pattern and the structure of a multi-slot channel enables a faster response from the BS.

NOTE 2: This special procedure affects MAC operation only; the LLC re-transmission protocol is unchanged. The MAC should issue the TMA-REPORT indication primitive to the LLC only after the first transmission of the message.

#### 23.8.4.1.4 Reception on uplink STCH

This clause describes the procedure for BS reception on uplink slots that have been assigned for traffic.

The training sequence in each slot shall indicate whether stealing has occurred.

For normal training sequence 1 (i.e. SF = 0), the receiving BS shall assume that the slot contains only TCH.

For normal training sequence 2 (i.e. SF = 1), the first half slot shall be assumed to be STCH. Then the MAC PDU type shall indicate whether the first half slot was stolen for C-plane signalling (MAC-DATA PDU) or for U-plane signalling (MAC-U-SIGNAL PDU). The receiving BS shall inspect the MAC header(s) to discover whether the second half slot is also stolen.

- For U-plane signalling, the "second half slot stolen flag" shall indicate whether the second half slot is stolen.
- For C-plane signalling, PDU dissociation may be necessary within the first half slot.
- If the last PDU (or only PDU) in the first half slot is a MAC-DATA PDU containing "Length indication" not equal to  $111110_2$  nor  $111111_2$ , then the BS shall assume that the second half slot is not stolen.
- If the last PDU (or only PDU) in the first half slot is a MAC-DATA PDU containing "Length indication" =  $111110_2$  or  $111111_2$ , the BS shall assume that the second half slot is stolen. Also, for "Length indication" =  $111111_2$ , the BS shall assume the start of fragmentation and shall store the TM-SDU fragment.

If the second half slot is not stolen, the BS shall interpret the second half slot as TCH.

If the second half slot is stolen, the BS shall interpret the second half slot as STCH. Then the MAC PDU type shall indicate whether the second half slot was stolen for C-plane signalling (MAC-DATA or MAC-END PDU) or for U-plane signalling (MAC-U-SIGNAL PDU). For C-plane signalling, PDU dissociation may be necessary within the second half slot.

In the case of fragmentation: If the second half slot is not decodeable, or if the second half slot does not include a MAC-END PDU, then the BS should discard the first fragment. Otherwise, it shall append the fragment from the MAC-END PDU to the already received fragment and shall assume that the received TM-SDU is complete.

## 23.8.4.2 Downlink stealing

### 23.8.4.2.1 Transmission on downlink STCH

The BS may steal from a traffic circuit to send C-plane signalling messages on the downlink, either to the MS(s) receiving the traffic or to other MSs on the channel. However, the BS designer should note that frequent stealing would degrade the quality of the circuit, especially for circuit mode data calls. Also, it is recommended that, when the BS requires to steal, it steals from TCH in preference to overwriting U-plane signalling. This recommendation applies particularly to end-to-end encrypted calls.

Valid PDUs for C-plane STCH on the downlink are:

- MAC-RESOURCE PDU: first or second half slot;
- SYSINFO PDU: first or second half slot;
- ACCESS-DEFINE PDU: first or second half slot;
- MAC-END PDU: second half slot only (final fragment).

The appropriate PDU for U-plane STCH is:

- MAC-U-SIGNAL PDU: first or second half slot.

The downlink MAC-U-SIGNAL PDU should be identical to that received from the transmitting station, except that the setting of the "second half slot stolen flag" may be changed when appropriate.

The MAC header of a MAC-U-SIGNAL PDU sent in a first half slot shall indicate whether the second half slot is also stolen, using the second half slot stolen flag. If the second half slot is stolen, it may contain either U-plane or C-plane signalling (as indicated by the first MAC header in the second half slot).

For C-plane stealing within the first half slot, PDU association may be used. The PDU type or "Length indication" in the last PDU (or only PDU) in the first half slot shall indicate whether the second half slot is also stolen.

- i) TMB-SAP PDU (SYSINFO or ACCESS-DEFINE): second half slot not stolen.

Then the second half slot shall contain TCH (MAC-TRAFFIC PDU).

- ii) MAC-RESOURCE PDU with "Length indication"  $\leq 010000_2$ : second half slot not stolen.

Then the second half slot shall contain TCH (MAC-TRAFFIC PDU).

- iii) MAC-RESOURCE PDU with "Length indication" =  $111110_2$ : second half slot stolen, no fragmentation.

Then the second half slot may contain either U-plane or C-plane signalling (as indicated by the first MAC header in the second half slot). For C-plane signalling, PDU association may be used within the second half slot.

- iv) MAC-RESOURCE PDU with "Length indication" =  $111111_2$ : second half slot stolen, start of fragmentation.

Then the final fragment should be sent in the second half slot, using the MAC-END PDU. PDU association may be used within the second half slot.

NOTE 1: The BS may use the Null PDU as a dummy C-plane message on STCH, in either the first half slot, second half slot or both. As always, "Address type"  $000_2$  in the MAC-RESOURCE PDU indicates a downlink Null PDU. In the first half slot, the "Length indication" indicates whether or not the second half slot is stolen.

NOTE 2: The SYSINFO PDU cannot be sent in the first half slot if the second half slot is also to be stolen.

If the second half slot is to be stolen, the ACCESS-DEFINE PDU can be included in the first half slot if required, but not as the last PDU (or only PDU) in the first half slot.

### 23.8.4.2.2 Reception on downlink STCH

This procedure shall be used by all MSs that are receiving the downlink channel.

All MSs that are receiving the channel shall check whether C-plane messages are addressed to itself and, if so, shall process the message and deliver any TM-SDU to the LLC. Only MSs that are currently permitted to process received traffic shall pass the TCH, and the TM-SDU in U-plane signalling (MAC-U-SIGNAL PDU), to the U-plane application.

The training sequence in each slot shall indicate whether stealing has occurred.

For normal training sequence 1 (i.e. SF = 0), the receiving MS shall assume that the slot contains only TCH.

For normal training sequence 2 (i.e. SF = 1), the first half slot shall be assumed to be STCH. Then the MAC PDU type shall indicate whether the first half slot was stolen for C-plane (TMA-SAP/TMB-SAP) or for U-plane (TMD-SAP) signalling. The receiving MAC shall inspect the MAC header(s) to discover whether the second half slot is also stolen.

- For U-plane signalling, the "second half slot stolen flag" shall indicate whether the second half slot is stolen.
- For C-plane signalling, PDU dissociation may be necessary within the first half slot.
- If the last PDU (or only PDU) in the first half slot is a TMB-SAP PDU, or a MAC-RESOURCE PDU (or Null PDU) containing "Length indication" not equal to 111110<sub>2</sub> nor 111111<sub>2</sub>, then the MS shall assume that the second half slot is not stolen.
- If the last PDU (or only PDU) in the first half slot is a MAC-RESOURCE PDU (or Null PDU) containing "Length indication" = 111110<sub>2</sub> or 111111<sub>2</sub>, the MS shall assume that the second half slot is stolen. Also, for "Length indication" = 111111<sub>2</sub>, the addressed MS(s) shall assume the start of fragmentation and shall store the TM-SDU fragment.

If the first half slot is not decodeable, the MS designer should choose an appropriate method for processing the second half of the slot.

**EXAMPLE:** The MS might make a first assumption that the second half slot is stolen, but revise that decision if the CRC fails. (This method could be particularly useful at the start of an encrypted transmission when encryption synchronization might be sent in both halves of the slot.) Otherwise the MS could treat the second half slot as "CRC fail" TCH.

If the second half slot is not stolen, the receiving MS shall interpret the second half slot as TCH.

If the second half slot is stolen, the MS shall interpret the second half slot as STCH. Then the MAC PDU type shall indicate whether the second half slot was stolen for C-plane (TMA-SAP/TMB-SAP) or U-plane (TMD-SAP) signalling. If the second half slot is not decodeable, the MS should regard the MAC block as C-plane signalling with CRC failure.

In the case of C-plane signalling, PDU dissociation may be necessary within the second half slot.

If the second half slot is not decodeable, or if the second half slot does not include a MAC-END PDU, an MS-MAC that stored a first fragment in the first half slot shall discard that fragment. Otherwise, it shall append the fragment from the MAC-END PDU to the already received fragment, and shall deliver the complete TM-SDU to the LLC.

## 23.8.5 BS operation

For traffic slots received on the uplink:

- a) for normal training sequence 1, channel decoding (and re-encoding) may be performed at the BS, allowing error correction for multiple hops;
- b) channel decoding (and re-encoding) should be performed at the BS in the case of normal training sequence 2, in order that the BS can recognize C-plane stealing;
- c) when a half slot has been stolen on the uplink for C-plane signalling, the BS should replace the stolen half slot (e.g. with another C-plane message or with the Null PDU or with substitution traffic) before transmission on the downlink.

The BS should pass the U-plane signalling and TCH on towards the destination. The timing and ordering and half-slot pairing of the U-plane information (signalling and TCH) shall be preserved. The BS may replace (i.e. overwrite) U-plane information when performing C-plane stealing, but shall not move the replaced U-plane information to a different position.

If the BS does not receive data from the sending MS, e.g. in the case of U-plane DTX, it should still transmit on the downlink channel to the receiving MS(s). For example, it could fill the slot with two stolen half slots each containing the C-plane Null PDU, or it could fill the slot with substitution traffic.

If the BS is decoding and re-encoding the traffic for a circuit mode data call with an interleaving depth of  $N = 4$  or  $8$  then:

- i) the BS should delay U-plane signalling by  $N - 1$  traffic frames before transmission on the downlink;

NOTE 1: This procedure for  $N = 4$  or  $8$  means that the BS transmits the U-plane data stream with the U-plane signalling in the same position as when the MS transmitted it. This position may be important if the U-plane signalling is carrying end-to-end encryption synchronization.

The need for the procedure arises because the de-interleaving process causes the circuit mode data to be delayed by  $N - 1$  traffic frames relative to the U-plane signalling. The receiving MS's procedure (see clause 23.8.3.2) takes account of the relative delay over the air interface if the BS does not de-interleave the traffic before transmission on the downlink. The BS needs to compensate for the additional relative delay introduced by its de-interleaving and re-interleaving of the traffic.

- ii) after a U-TX CEASED or U-DISCONNECT PDU has been received from the transmitting MS, the BS should ensure that it has been able to issue  $N - 1$  slots containing tail bits to the lower MAC at the end of the data transmission (on each allocated slot in the case of a multi-slot channel) before sending the D-TX CEASED, D-RELEASE or D-DISCONNECT PDU to receiving MS(s).

NOTE 2: These tail bits are needed to complete the interleaving of the circuit mode data that has been received from the transmitting MS.

Some examples of scenarios for call set-up and channel usage for circuit mode calls are illustrated in annex D.

## 28 TETRA Packet Data Protocol

### 28.0 General

Clause 28 defines the TETRA Packet Data Protocol (PDP) for packet data operation. The TETRA packet data service is built on top of the Mobile Link Entity (MLE) defined in clauses 17 and 18 of the present document.

NOTE 1: The TETRA packet data service is separate from the Connection Oriented Network Service (CONS) and the Specific Connectionless Network Service (SCLNS) which were defined in clauses 24 to 27 of the ETSI ETS 300 392-2, edition 1.

The TETRA packet data service provides mechanisms to convey different higher layer protocols. The present document supports the following network layer protocols:

- Internet Protocol (IP), versions 4 and 6.

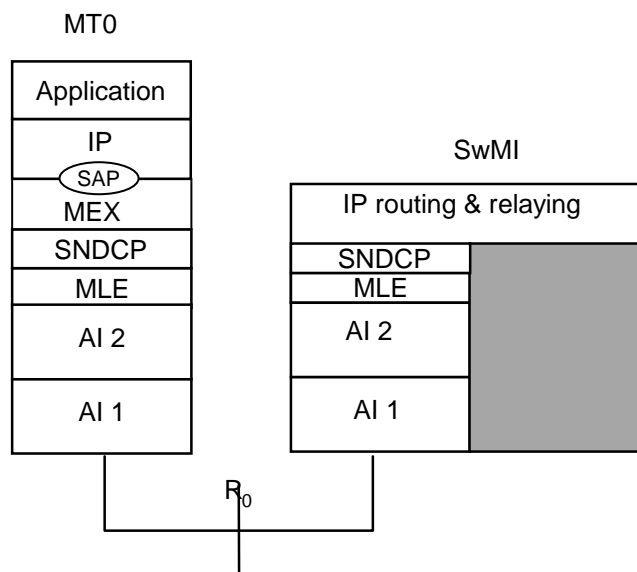

TETRA packet data extends TETRA to act as an IP subnet. This enables application programmers to build their applications in a well-standardized environment.

At the MS side the IP and the higher layers on top of it may be located at:

- MT0;
- TE2 where the protocol used between TE2 and MT2 is defined in ETSI EN 300 392-5 [7];
- TE where the protocol used between TE and MT0 is outside the scope of the present document and ETSI EN 300 392-5 [7];
- MEX layer (clause 30).

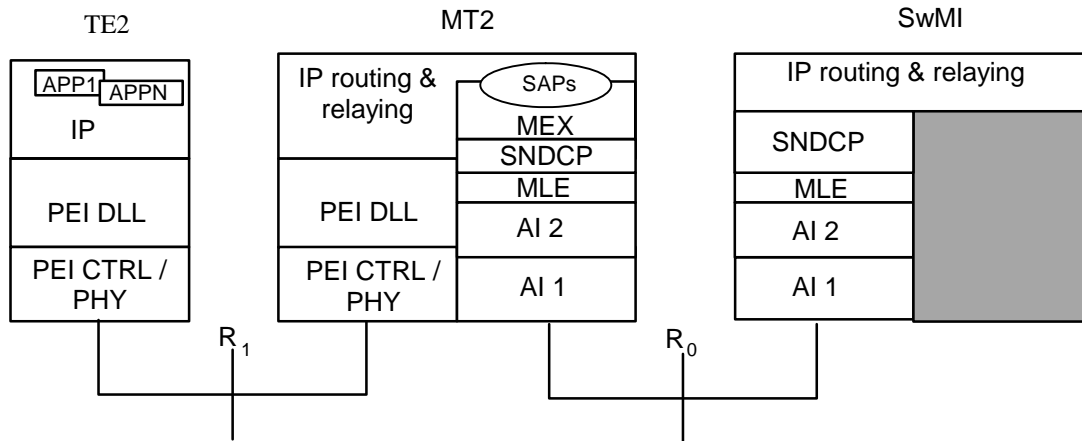

The implementation of the SwMI's IP routing and relaying as well as the connection to external networks is outside the scope of the present document.

Figure 28.1 illustrates the usage of TETRA packet data when the application is located in MT0.

**Figure 28.1: Usage of TETRA packet data for MT0 IP application**

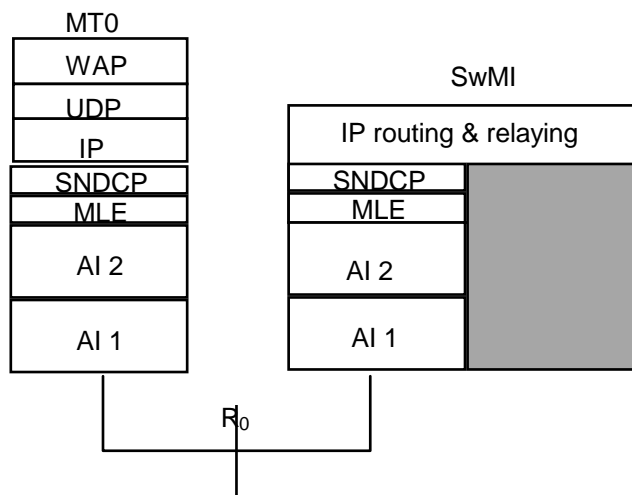

Figure 28.2 illustrates the usage of TETRA packet data when the applications use IP protocol and are located in TE2. Mapping between PEI DLL (MT2) and MEX is via the TNMXPI-SAP (see clause 30).

**Figure 28.2: Usage of TETRA packet data for TE2 IP application**

The Wireless Application Protocol (WAP) architecture, see WAP2.0 [i.9], defines a framework to meet the challenges of the advanced services, differentiation and fast/flexible service creation in wireless networks. The WAP defines a set of protocols in transport, session and application layers.

The upper layers of WAP will be independent of the underlying wireless network, while the transport layer should be adapted to specific features of underlying services. This adaptation to TETRA packet data is, however, outside of the scope of the present document. When used in conjunction with the TETRA packet data service, it is recommended that WAP be located on top of UDP/IP. Figure 28.3 illustrates the recommended usage of TETRA packet data when the application is a WAP application and it is located in MT0.

**Figure 28.3: Usage of TETRA packet data for MT0 WAP application**

NOTE 2: The MEX layer, defined in clause 30 of the present document, may be used to enhance the interface between SNDCP and its user applications.

## 28.1 Subnetwork Dependent Convergence Protocol (SNDCP) overview

The Subnetwork Dependent Convergence Protocol (SNDCP) is a TETRA specific network layer protocol that has two main functions:

- 1) to negotiate and maintain PDP contexts between an MS and the SwMI. A unique primary PDP context is established for each PDP address active (i.e. which requires packets to be routed to it) on the network. The primary PDP context activation procedure involves the binding of a PDP address to a TETRA ITSI and also the optional negotiation of compression algorithms and QoS parameters to be used during data transfer. Secondary PDP context activation involves binding the secondary PDP context to the PDP address of a primary PDP context and also the optional negotiation of compression algorithms and QoS parameters to be used during data transfer;
- 2) to control PDP data transfer between MS and SwMI. Data transfer is unacknowledged (i.e. SNDCP does not perform retransmissions); however, SNDCP allows the service user to select the acknowledged or unacknowledged layer 2 services for data transfer over the air interface. SNDCP provides mechanisms by which data may be compressed before being transmitted over the air interface.

Figure 28.4 describes the protocol model for TETRA packet data and the SNDCP position in it.

NOTE: Legend:

**Subnetwork Dependent Convergence Protocol (SNDCP):** TETRA specific Network layer protocol that shall be used to negotiate and maintain PDP contexts between MS and SwMI

**Mobile Link Entity (MLE):** MLE protocol discriminator entity (data transfer) routes TETRA Packet data signalling and data to corresponding TETRA Packet data SAP at the peer entity (SwMI/MS).

**Logical Link Control (LLC):** This layer provides a logical link.

**Medium Access Control (MAC):** This controls the access signalling (request and grant) procedures for the radio channel, and the mapping of LLC frames onto the TETRA physical channel.

**Air Interface layer 1 (AI-1):** As defined in the present document.

**Figure 28.4: Subnetwork Dependent Convergence Protocol (SNDCP)**

Before a MS may gain access to any SNDCP services, it firstly goes through a packet data registration procedure, called PDP context activation. PDP context activation is initiated by the MS. The MS may activate primary PDP contexts and secondary PDP contexts. Activation of a primary PDP context involves the negotiation of a PDP address (e.g. an IPv4 address) and other parameters to be used during data transfer. Each primary PDP context should have a different PDP address. When the MS has established one or more primary PDP contexts, it may request establishment of secondary PDP contexts. A secondary PDP context derives its PDP address from a primary PDP context and is used by the SwMI to differentiate the QoS given to different types of packets being sent to the same PDP address. The SwMI uses a QoS filter to determine if a downlink packet should use a secondary PDP context. If a downlink packet does not match the PDP address and the QoS filter of any secondary PDP context, the SwMI should instead send the packet via the primary PDP context for the relevant PDP address. The MS SNDCP may also specify a differentiated services field ("diffserv") filter for a secondary PDP context. The SwMI may inspect the lower 5 bits (4 to 0) of the 6-bit Differentiated Services Code Point (DSCP) in downlink IP packet headers and route the packets through a secondary PDP context with a matching diffserv filter.

If the MS does not specify a QoS filter during activation of a secondary PDP context, the SwMI should generate an automatic QoS filter.

**EXAMPLE:** The SwMI may generate an automatic QoS filter by recording the source port numbers and NSAPIs of uplink TCP/IP and UDP/IP packets received via secondary PDP contexts and use this to filter downlink packets on the basis of the downlink packets' destination IP addresses and destination ports.

PDP data transfer normally takes place over an assigned secondary control channel (assigned SCCH), termed in this specification a Packet Data CHannel (PDCH). An advanced link is set up before data transfer may begin on the PDCH using the acknowledged layer 2 service. When a MS has data to transfer, it implicitly requests permission to switch to the PDCH. If accepted, the SwMI normally responds with a channel allocation, directing the MS to a PDCH.

**NOTE:** The SwMI may allow the MS to use the MCCH or MCCH-Q (or common SCCH) for the exchange of packet data.

The protocol for SNDCP is described in terms of a state machine. There are three main states which are defined for both the MS and SwMI, namely READY, STANDBY and IDLE.

READY state typically implies a MS is located on a PDCH and is currently engaged in data transfer or has recently (defined by a timer) been engaged in packet data transfer.

STANDBY state implies a MS is no longer on a PDCH i.e. the MS has not recently (defined by a timer) been engaged in data transfer.

IDLE state implies that a MS has no PDP contexts activated.

A more complete description of SNDCP is given in the following clauses.

## 28.2 SNDCP service description

### 28.2.1 Introduction

This clause describes the services offered by the Subnetwork Dependent Convergence Protocol (SNDCP) entity for the voice plus data TETRA layer 3 air interface.

### 28.2.2 Services offered

SNDCP shall be a service provider for packet data users. The services shall be made available through the SNDCP Service Access Point (SN-SAP). The SNDCP procedures and protocol description are defined in clauses 28.3 and 28.4.

The services offered shall be:

- PDP context activation and PDP context deactivation;
- PDP context modification;
- Negotiation and modification of QoS requirements;
- Packet Data CHannel (PDCH) handling;
- Multiplexing of N-PDUs from one or several higher protocol entities onto a single layer 2 connection;
- Mapping of SN primitives received from the network layer into corresponding MLE-UNITDATA request primitives to be passed to the MLE;
- If data priority is not supported:
  - management of the delivery sequence according to the PDU priority of SN-UNITDATA request and SN-DATA request primitives;

- If data priority is supported:
  - management of the delivery sequence according to the PDU priority and data priority of SN-UNITDATA request and SN-DATA request primitives;
  - mapping of N-PDU data priorities into a priority for reserved access;
- Compression and recovery of redundant protocol control information (e.g. TCP/IP header). Header compression is performed independently for each NSAPI;
- Compression and recovery of redundant user data. Data compression is performed independently for each NSAPI;
- Interface to MEX mediated applications and applications which bypass MEX (see clause 30).

The SwMI indicates support for the SNDSCP service on conventional access cells in the D-MLE-SYSINFO and D-MLE-SYSINFO-Q PDUs (in the "BS service details" information element). A direct access cell always supports the SNDSCP service while the "system wide services" information element in the D-MLE-SYSINFO-DA (and the D-MLE-SYNC-DA) PDU is indicating "normal mode" (system wide services supported). It is optional for the DA cell to support the SNDSCP service while the "system wide services" information element in the D-MLE-SYSINFO-DA (and the D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported".

The MS SNDSCP shall not attempt to use the SNDSCP service on a conventional access cell that indicates no support for the SNDSCP service. If the MS SNDSCP possesses activated PDP contexts at the time that the SwMI indicates that the present cell does not support the SNDSCP service, the MS SNDSCP shall cease use of its activated PDP contexts, but may attempt to continue using the activated PDP contexts if the SwMI later indicates that the present cell does support the SNDSCP service or if the MS performs a cell reselection to a DA cell or to a CA cell that indicates support for the SNDSCP service.

The MS SNDSCP shall not attempt to use the SNDSCP services on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

## 28.2.3 Service Primitives

### 28.2.3.0 General

The services shall be provided through primitives at the service access point SN-SAP. This clause describes the primitives and their parameters.

Mapping of various protocols to the SNDSCP operation is defined with respect to an abstract underlying service. The underlying service consists of the following primitives:

- SN-DATA {Request, Indication};
- SN-DELIVERY {Indication};
- SN-NSAPI ALLOC {Request, Indication, Confirm};
- SN-NSAPI CONFIGURE {Request, Confirm};
- SN-NSAPI DEALLOC {Request, Indication};
- SN-NSAPI MODIFY {Request, Indication, Confirm};
- SN-QOS {Request, Indication};
- SN-UNITDATA {Request, Indication};
- SN-PAGE { Request, Indication, Response, Confirm}.

### 28.2.3.1 Primitive descriptions

In parameter descriptions:

- M = Mandatory:
- O = Optional:
- - = Not allowed.

**SN-DATA request/indication:** SN-DATA primitive is used for acknowledged data transfer service at the LLC. The receipt of data shall be confirmed by the LLC layer.

Parameters of the primitive shall be as shown in table 28.1.

**Table 28.1: Parameters for the primitive SN-DATA**

| Parameter  | Request        | Indication |
|--|----------------|------------|
| NSAPI  | M              | M          |
| Handle   | M              | -          |
| PDU priority   | O (see note 1) | -          |
| Data priority  | O (see note 2) | -          |
| Data importance  | O (see note 3) | -          |
| Schedule surplus flag  | O (see note 4) | -          |
| N-PDU  | M              | M          |
| NOTE 1: If PDU priority is not given in the primitive, then the value assigned by the SwMI during context activation is used.            |                |            |
| NOTE 2: If the data priority is not given in the primitive, then the value "undefined" should be assumed by SNDCCP.                      |                |            |
| NOTE 3: If the data importance is not given in the primitive, then the value "low" should be assumed by SNDCCP.                          |                |            |
| NOTE 4: If the schedule surplus flag is not given in the primitive then the value "not surplus to schedule" should be assumed by SNDCCP. |                |            |

**SN-DELIVERY indication:** SN-DELIVERY primitive is used to indicate that SNDCCP has completed its transmission of the N-PDU in a SN-DATA request primitive (success/failure/deleted or cancelled by SNDCCP) or SN-UNITDATA request primitive (failure/deleted or cancelled by SNDCCP).

Parameters of the primitive shall be as shown in table 28.2.

**Table 28.2: Parameters for the primitive SN-DELIVERY**

| Parameter       | Indication |
|-----------------|------------|
| Handle          | M          |
| Delivery report | M          |

**SN-NSAPI ALLOC request/indication/confirm:** SN-NSAPI ALLOC primitive is used to set NSAPI into use.

Parameters of the primitive shall be as shown in table 28.3.

**Table 28.3: Parameters for the primitive SN-NSAPI ALLOC**

| Parameter   | Request<br>(MS only) | Indication<br>(SwMI only) | Confirm<br>(MS only)  |
|---|----------------------|---------------------------|-----------------------|
| NSAPI   | M                    | M                         | M                     |
| NSAPI alloc report  | -                    | -                         | M                     |
| PDP type  | M                    | M                         | C (see note 3)        |
| PDP address   | C (see note 1)       | M                         | C (see notes 2 and 3) |
| DCOMP negotiation   | O                    | O                         | O (see note 3)        |
| PCOMP negotiation   | O                    | O                         | O (see note 3)        |
| NSAPI alloc reject cause  | -                    | -                         | C (see note 4)        |
| PDU priority max  | -                    | -                         | C (see note 3)        |
| NSAPI data priority   | O (see note 6)       | -                         | -                     |
| Maximum transmission unit   | -                    | -                         | M                     |
| Mobile IPv4 information   | -                    | -                         | C (see notes 3 and 5) |
| NSAPI QoS negotiation   | O                    | O                         | O (see note 3)        |
| NOTE 1: Conditional on PDP type. PDP address not present in case of IPv4 dynamic address negotiation or IPv6.               |                      |                           |                       |
| NOTE 2: Conditional on PDP type. PDP address not present in case of IPv6 or Mobile IPv4 FA care of address requested.       |                      |                           |                       |
| NOTE 3: Conditional on NSAPI alloc report. Not present in case of NSAPI alloc report set to "Failure".                      |                      |                           |                       |
| NOTE 4: Conditional on NSAPI alloc report. Present in case of NSAPI alloc report set to "Failure".                          |                      |                           |                       |
| NOTE 5: Conditional on PDP type. Present if PDP type set to Mobile IPv4.  |                      |                           |                       |
| NOTE 6: If the "NSAPI data priority" is not given in the primitive, then the value "undefined" should be assumed by SNDCCP. |                      |                           |                       |

**SN-NSAPI CONFIGURE request/confirm:** SN-NSAPI CONFIGURE primitive is used to make local modifications to the characteristics of an activated NSAPI.

Parameters of the primitive shall be as shown in table 28.4.

**Table 28.4: Parameters for the primitive SN-NSAPI CONFIGURE**

| Parameter           | Request | Confirm |
|---------------------|---------|---------|
| NSAPI               | M       | M       |
| NSAPI data priority | M       | M       |

**SN-NSAPI DEALLOC request/indication:** SN-NSAPI DEALLOC primitive is used to withdraw NSAPI from use.

Parameters of the primitive shall be as shown in table 28.5.

**Table 28.5: Parameters for the primitive SN-NSAPI DEALLOC**

| Parameter   | Request      | Indication   |
|---|--------------|--------------|
| Deactivation type   | M            | M            |
| NSAPI   | C (see note) | C (see note) |
| NOTE: Not present if Deactivation Type is set to "Deactivate All NSAPIs". |              |              |

**SN-NSAPI MODIFY request/indication/confirm:** SN-NSAPI MODIFY primitive is used to modify the characteristics of an activated NSAPI which have been agreed with the SwMI.

Parameters of the primitive shall be as shown in table 28.6.

**Table 28.6: Parameters for the primitive SN-NSAPI MODIFY**

| Parameter   | Request | Indication | Confirm        |
|---|---------|------------|----------------|
| NSAPI   | M       | M          | M              |
| NSAPI modify report   | -       | -          | M              |
| NSAPI modify reject cause   | -       | -          | C (see note 1) |
| NSAPI QoS negotiation (see note 3)  | O       | O          | O (see note 2) |
| Schedule availability   | -       | O          | -              |
| NSAPI usage (see note 3)  | O       | -          | -              |
| NOTE 1: Conditional on NSAPI modify report. Present only in case of NSAPI modify report set to "failure".         |         |            |                |
| NOTE 2: Conditional on NSAPI modify report. Not present in case of NSAPI modify report set to "failure".          |         |            |                |
| NOTE 3: Only one of "NSAPI QoS negotiation" and "NSAPI usage" should be included in a single primitive, not both. |         |            |                |

**SN-QOS request/indication:** SN-QOS primitive is used to negotiate about QoS to the peer entity.

Parameters of the primitive shall be as shown in table 28.7.

**Table 28.7: Parameters for the primitive SN-QOS**

| Parameter  | Request | Indication |
|--|---------|------------|
| QoS requested  | M       | M          |
| QoS minimum  | M       | -          |
| QoS negotiated   | -       | M          |
| QoS negotiation result   | -       | M          |
| NOTE: It is recommended that this primitive is used only to set parameters within the MS SNDPCP entity, to be used at a later stage during advanced link setup negotiation. This primitive should not in itself trigger the establishment or resetting of the advanced link. |         |            |

NOTE: The SN-QOS request primitive is retained for backward compatibility with previous versions of this document, and is applicable only to  $\pi/4$ -DQPSK modulation. The optional NSAPI QoS negotiation parameter included in the SN-NSAPI ALLOC and SN-NSAPI MODIFY primitives has more general applicability, and should be used instead of the SN-QOS request primitive.

**SN-UNITDATA request/indication:** SN-UNITDATA primitive is used for unacknowledged data transfer service at the LLC. The receipt of data is not confirmed by the SNDCP or lower layers.

Parameters of the primitive shall be as shown in table 28.8.

**Table 28.8: Parameters for the primitive SN-UNITDATA**

| Parameter   | Request        | Indication |
|---|----------------|------------|
| NSAPI   | M              | M          |
| Handle  | M              | -          |
| PDU priority  | O (see note 1) | -          |
| Data priority   | O (see note 2) |            |
| Data importance   | O (see note 3) |            |
| Schedule surplus flag   | O (see note 4) |            |
| N-PDU   | M              | M          |
| NOTE 1: If PDU priority is not given in the primitive, then the value assigned during context activation is used.                       |                |            |
| NOTE 2: If the data priority is not given in the primitive, then the value "undefined" should be assumed by SNDCP.                      |                |            |
| NOTE 3: If the data importance is not given in the primitive, then the value "low" should be assumed by SNDCP.                          |                |            |
| NOTE 4: If the schedule surplus flag is not given in the primitive then the value "not surplus to schedule" should be assumed by SNDCP. |                |            |

**SN-PAGE request/indication/response/confirm:** SN-PAGE primitive is used as part of the TETRA packet data paging mechanism.

Parameters of the primitive shall be as shown in table 28.9.

**Table 28.9: Parameters for the primitive SN-PAGE**

| Parameter         | Request (SwMI only) | Indication (MS only) | Response (MS only) | Confirm (SwMI only) |
|-------------------|---------------------|----------------------|--------------------|---------------------|
| NSAPI             | M                   | M                    | M                  | M                   |
| Reply requested   | M                   | M                    | -                  | -                   |
| PD service status | -                   | -                    | M                  | M                   |

### 28.2.3.2 Parameter descriptions

CONTEXT\_READY time =

- track READY timer;
- 200 ms;
- 500 ms;
- 700 ms;
- 1 s;
- 2 s;
- 3 s;
- 5 s;
- 10 s;
- 20 s;
- 30 s;

- 60 s;
- 120 s;
- 180 s;
- 300 s.

Data class =

- Real-time class - layer 2 link optimized for data which cannot tolerate delivery delay (late packets discarded by the receiving application);
- Telemetry class - layer 2 link optimized for intermittent data which can tolerate moderate delivery delay and packet loss;
- Background class - layer 2 link optimized for data which are intolerant of packet loss.

Data importance =

- Low;
- Medium;
- High.

NOTE 0: In circumstances where the MS SNDCP decides to delete or cancel untransmitted N-PDUs, "data importance" allows the MS SNDCP to preferentially delete or cancel N-PDUs containing lower-importance data. Data importance is not transmitted over the air interface.

Data priority =

- 0 Lowest data priority;  
etc.;
- 7 Highest data priority.

DCOMP negotiation =

- This parameter may contain several different data compression methods, such as Recommendation ITU-T V.42bis [27], and their parameters negotiated with the peer entity.

Deactivation type =

- Deactivate all NSAPIs;
- Deactivate NSAPI given in the primitive.

Delay class =

- Low;
- Moderate;
- High;
- Unpredictable.

Table 28.10 defines the meaning of the delay class values.

**Table 28.10: Packet delays for different delay classes**

| Delay Class   | N-PDU size ≤ 128 octets |                         | 128 < N-PDU size ≤ 1 024 octets |                         | 1 024 < N-PDU size ≤ 2 002 octets |                         |
|---------------|-------------------------|-------------------------|---------------------------------|-------------------------|-----------------------------------|-------------------------|
|               | Mean transfer delay (s) | 95 percentile delay (s) | Mean transfer delay (s)         | 95 percentile delay (s) | Mean transfer delay (s)           | 95 percentile delay (s) |
| Low           | < 1                     | < 3                     | < 3                             | < 7                     | < 5                               | < 10                    |
| Moderate      | < 5                     | < 25                    | < 15                            | < 75                    | < 30                              | < 150                   |
| High          | < 50                    | < 250                   | < 75                            | < 375                   | < 110                             | < 560                   |
| Unpredictable | Undefined               | Undefined               | undefined                       | undefined               | undefined                         | undefined               |

NOTE 1: For packets sizes up to 1 024 octets, the delays for moderate and high classes match those for GPRS, see ETSI TS 122 060 [i.10].

NOTE 2: Real-time class data requires the low delay class; if real-time class data is specified, the low delay class should be assumed by default.

NOTE 3: The delay values are for MS to MS communication in a single network (SwMI) including random access delay.

Delivery report =

- Success;
- Failure;
- Deleted or cancelled by SNDSCP.

DSCP =

- differentiated services code point.

Handle =

- Defines the handle used to generate a mapping between SN-DATA or SN-UNITDATA request primitives and SN-DELIVERY indication primitives.

Maximum transmission unit =

- This is the maximum size of N-PDU which may be presented by the MS service user to SNDSCP for transport over the air interface. This typically represents the maximum size of IP packet (prior to adding SNDSCP header and performing compression) which may be carried over the air-interface.

Mean active throughput =

- This is the mean throughput of N-PDUs expected by the SNDSCP service user while the PDP context is actively transmitting or receiving data (i.e. while the PDP context's CONTEXT\_READY timer is active, if supported, or while the READY timer is active if CONTEXT\_READY timers are not supported).
- The values are as for minimum peak throughput.

Mean throughput =

- This is the mean throughput of N-PDUs expected by the SNDSCP service user, averaged over the expected lifetime of the PDP context. It is given in units of octets/hour.
  - 100 (~0,22 bits/s);
  - 200 (~0,44 bits/s);
  - 500 (~1,11 bits/s);
  - 1 000 (~2,2 bits/s);

- 2 000 (~4,4 bits/s);
- 5 000 (~11,1 bits/s);
- 10 000 (~22 bits/s);
- 20 000 (~44 bits/s);
- 50 000 (~111 bits/s);
- 100 000 (~0,22 kbit/s);
- 200 000 (~0,44 kbit/s);
- 500 000 (~1,11 kbit/s);
- 1 000 000 (~2,2 kbit/s);
- 2 000 000 (~4,4 kbit/s);
- 5 000 000 (~11,1 kbit/s);
- 10 000 000 (~22 kbit/s);
- 20 000 000 (~44 kbit/s);
- 50 000 000 (~111 kbit/s);
- Best effort.

NOTE 4: These values follow those given for GPRS, see ETSI EN 301 344 [i.11].

Minimum peak throughput =

- This is the minimum peak throughput of N-PDUs in units of octets/s requested or offered for a particular PDP context. This is the minimum throughput required when the PDP context is at its most active; if the peak rate available is lower than this, the application may not be usable (though the application may be capable of using a higher rate than this).
  - < 1 000;
  - $\geq 1\ 000$ ;
  - $\geq 2\ 000$ ;
  - $\geq 4\ 000$ ;
  - $\geq 8\ 000$ ;
  - $\geq 16\ 000$ ;
  - $\geq 32\ 000$ ;
  - $\geq 64\ 000$ .

NOTE 5: The following examples show methods of providing the requested peak throughput in a reliable channel:

- a peak throughput less than 1 000 octets/s can be provided by any PDCH;
- a peak throughput  $\geq 1\ 000$  octets/s requires 4-QAM 25 kHz (3-, 4-slot),  $\pi/4$ -DQPSK (2-, 3-slot), etc.;
- a peak throughput  $\geq 2\ 000$  octets/s requires 4-QAM 50 kHz (3-, 4-slot),  $\pi/4$ -DQPSK (4-slot), etc.;
- a peak throughput  $\geq 4\ 000$  octets/s requires 4-QAM 100 kHz (3-, 4-slot), 4-QAM 150 kHz (2-slot), etc.;
- a peak throughput  $\geq 8\ 000$  octets/s requires 4-QAM 150 kHz (3-, 4-slot);

- a peak throughput  $\geq 16\ 000$  octets/s requires 16-QAM 150 kHz (4-slot), etc.;
- a peak throughput  $\geq 32\ 000$  octets/s requires 64-QAM  $r = \frac{1}{2}$ , 150 kHz (4-slot), etc.;
- a peak throughput  $\geq 64\ 000$  octets/s requires 64-QAM  $r = 1$ , 150 kHz (4-slot).

Mobile IPv4 Information =

- Information specific to Mobile IPv4 operation.

N-PDU =

- Any number of bits needed to carry a Network layer protocol PDU.

NSAPI =

- 0 Reserved;
- 1 Free;
- etc.;
- 14 Free;
- 15 Reserved.

NSAPI alloc reject cause =

- Undefined;
- MS not provisioned for Packet Data;
- IPv4 not supported;
- IPv6 not supported;
- IPv4 dynamic address negotiation not supported;
- IPv6 stateful address autoconfiguration not supported;
- IPv6 stateless address autoconfiguration not supported;
- Dynamic address pool empty;
- Static address not correct;
- Static address in use;
- Static address not allowed;
- Static IP address congestion;
- TETRA Packet Data not supported on this location area;
- TETRA Packet Data not supported on this network;
- Temporary rejection;
- Packet Data MS Type not supported;
- SNDCCP version not supported;
- Mobile IPv4 not supported;
- Mobile IPv4 Co-located Care of Addresses not supported;
- Maximum allowed PDP contexts per ITSI exceeded;

- User authentication failed;
- Activation rejected by external PDN;
- Access point name index not correct;
- No response from network;
- Bad response from network;
- NSAPI not available;
- NSAPI already allocated;
- Requested minimum peak throughput not available;
- Scheduled access not supported;
- Requested schedule not available;
- Requested QoS not available;
- Secondary PDP contexts not supported;
- Primary PDP context does not exist;
- Asymmetric QoS not supported;
- Automatic QoS filter not supported;
- Specified QoS filter not supported;
- QoS filter type not supported;
- QoS filter not available for primary PDP context;
- SNDCP service temporarily not available.

NSAPI alloc report =

- Failure;
- Success (Note that DCOMP negotiation, PCOMP negotiation and NSAPI QoS negotiation values might be changed).

NSAPI data priority =

- As data priority.

NSAPI modify reject cause =

- Undefined;
- Temporary rejection;
- No response from network;
- Bad response from network;
- NSAPI not activated;
- Requested minimum peak throughput not available;
- Scheduled access not supported;
- Requested schedule not supported;
- Requested QoS not available;
- Secondary PDP contexts not supported;
- Primary PDP context does not exist;
- Asymmetric QoS not supported;
- Automatic QoS filter not supported;
- Specified QoS filter not supported;
- QoS filter type not supported;
- QoS filter not available for primary PDP context;
- SNDCP service temporarily not available.

NSAPI modify report =

- Failure (the NSAPI QoS negotiation parameter was not changed from its previous value);
- Success (one or more of the items in the NSAPI QoS negotiation parameter were changed from their previous values).

NSAPI QoS negotiation =

- A set of: QoS for uplink and downlink or for uplink only, QoS for downlink, CONTEXT\_READY time, QoS filter (only when a secondary PDP context is requested) and scheduled access.

NSAPI Usage =

- Schedule paused;
- PDP context paused.

PCOMP negotiation =

- This parameter may contain several different protocol compression methods. They may be one or more of: TCP/IP header compression (not available for unacknowledged layer 2 service or real-time class data) and IP header compression.

PD service status =

- Available for packet data service;
- Temporarily unavailable for packet data service.

PDP address =

- IPv4 address (only when a primary PDP context is being requested); or
- NSAPI (only when a secondary PDP context is being requested).

PDP type =

- IPv4 (static address);
- IPv4 (dynamic address negotiation);
- IPv6;
- Mobile IPv4 - Foreign Agent care of address requested;
- Mobile IPv4 - Co-located care of address requested;
- Primary NSAPI (secondary PDP context requested).

PDU priority =

- 0 Lowest PDU priority;  
etc.;
- 7 Highest PDU priority.

PDU priority max =

- As PDU priority.

Port =

- A port number (0 to 65 535).

Port range =

- Lower limit of a range of port numbers (0 to 65 535);
- Upper limit of a range of port numbers (0 to 65 535).

QoS filter =

- A set of: QoS filter operation, QoS filter type and one of: port, port range or DSCP (port, port range and DSCP not required when QoS filter type = automatic QoS filter).

QoS filter operation =

- Add to any existing QoS filter for the specified PDP context;
- Replace any existing QoS filter for the specified PDP context;
- Remove from any existing QoS filter for the specified PDP context.

QoS filter type =

- Automatic QoS filter;
- All types of ports;
- UDP ports;
- TCP ports;
- Diffserv.

QoS for downlink =

- A set of: data class, minimum peak throughput, mean throughput, mean active throughput, delay class and reliability class.

QoS for uplink and downlink or for uplink only =

- A set of: data class, minimum peak throughput, mean throughput, mean active throughput, delay class and reliability class.

QoS minimum =

- As QoS requested.

QoS negotiated =

- As QoS requested.

QoS negotiation result =

- Success;
- Failure;
- Failure, try again.

NOTE 6: The QoS requested, QoS minimum and QoS negotiated and QoS negotiation result parameters are retained for compatibility with previous versions of this document. The NSAPI QoS negotiation parameter in the SN-NSAPI ALLOC and SN-NSAPI MODIFY request primitives should be used instead, if supported. SNDCP requires the information they contain to request any QoS other than background class operation with unspecified throughput, reliability and delay. For example, the NSAPI QoS negotiation parameter needs to be used if the application wishes to use scheduled access.

QoS requested =

- A set of:
  - Advanced link service (unacknowledged, acknowledged);
  - Maximum length of N-PDU;
  - Number of timeslots used per TDMA frame (1-4); and
  - Data transfer throughput (network dependent minimum, 1/32, 1/16, 1/8, 1/4, 1/2, maximum).

Reliability class =

- High (uses an acknowledged link with FCS enabled);
- Moderate (uses an acknowledged link with FCS disabled);
- Low (uses the unacknowledged basic link, normally with FCS disabled and no retransmissions).

Table 28.11 defines the reliability classes.

**Table 28.11: Definition of reliability classes**

| Reliability class                                       | Lost N-PDU Probability | Duplicate N-PDU Probability | Out of Sequence N-PDU Probability | Corrupt N-PDU Probability |
|---|------------------------|-----------------------------|-----------------------------------|---------------------------|
| High  | $< 10^{-9}$            | $< 10^{-9}$                 | $< 10^{-9}$                       | $< 10^{-9}$               |
| Moderate  | $< 10^{-4}$            | $< 10^{-9}$                 | $< 10^{-5}$                       | $< 10^{-4}$               |
| Low (see note 1)  | Undefined              | 0 (see note 2)              | 0 (see note 2)                    | $< 10^{-4}$               |
| NOTE 1: Uses an unacknowledged link.                    |                        |                             |                                   |                           |
| NOTE 2: Applies only if each N-PDU is transmitted once. |                        |                             |                                   |                           |

NOTE 7: Real-time class data uses the low reliability class.

The lost N-PDU probability for the low reliability class is shown in table 28.11 as "undefined". However, for example, some applications may need the lost N-PDU probability for real-time class data to be less than  $2,5 \times 10^{-2}$ .

Reply requested =

- SNDCP response required;
- SNDCP response not required.

Schedule availability =

- Available;
- Cancelled;
- Suspended.

Schedule repetition period =

- 4 slot durations;
- 5 slot durations;
- etc.;
- 706 slot durations (10 s).

NOTE 8: A slot has a duration of  $85/6$  ms.

Schedule surplus flag =

- Not surplus to schedule;
- Surplus to schedule.

Schedule timing error =

- $\leq 1$  slot duration;
- $\leq 2$  slot durations;
- $\leq 4$  slot durations;
- $\leq 8$  slot durations;
- $\leq 16$  slot durations;
- $\leq 32$  slot durations;
- $\leq 64$  slot durations;
- $\leq 128$  slot durations.

NOTE 9: A slot has a duration of  $85/6$  ms.

NOTE 10: The SwMI sets the earliest timing of successive scheduled slot grants relative to the time of the first slot grant. The schedule timing error is the maximum acceptable delay of a scheduled slot grant beyond the earliest time of a scheduled slot grant. The SNDCP application should not propose a schedule timing error which is greater than the schedule repetition period.

Scheduled Access =

- A set of:
  - schedule repetition period;
  - schedule timing error;
  - scheduled number of N-PDUs per grant;
  - scheduled N-PDU size.

NOTE 11: The scheduled N-PDU size parameter should be repeated as many times as necessary to indicate a size for each scheduled N-PDU per grant.

Scheduled N-PDU size =

- 1 octet;
- 2 octets;
- etc.;
- 2 002 octets.

Scheduled number of N-PDUs per grant =

- 1;
- 2;
- etc.;
- 7.

## 28.2.4 Definition of SNDCP states and state transitions

### 28.2.4.0 General

The SNDCP activities related to a TETRA MS are characterized by one of eight different SNDCP states: CLOSED, IDLE, IDLE-Temporary Break, STANDBY, STANDBY-Temporary Break, RESPONSE-WAITING, READY and READY-Temporary Break. The SNDCP activities related to a TETRA SwMI are characterized by one of three different SNDCP states: IDLE, STANDBY and READY.

Each state describes a certain level of functionality and information allocated to the involved entities. The SNDCP state relates only to SNDCP activities of a subscriber represented by the ITSI. It is independent of number of PDP contexts for that subscriber.

It is optional for a MS to support multiple PDP contexts. It is also optional for a SwMI to support multiple PDP contexts for a single ITSI.

NOTE: If multiple PDP contexts are used by a single ITSI, then the MS will release all its PDP contexts at the same time when entering to state IDLE from state STANDBY. The SwMI may use SwMI originated PDP Deactivation procedure in order to control PDP context lifetimes separately.

### 28.2.4.1 CLOSED

CLOSED state is valid for a MS only. In CLOSED state access to the communication resources is unavailable (e.g. due to MS not being registered or being temporarily disabled) and SNDCP is not permitted to communicate with its peer entity.

In CLOSED state, the MS does not have any PDP contexts active.

When entering state CLOSED, the READY, CONTEXT\_READY, RESPONSE\_WAIT and STANDBY timers are stopped. If the MS supports data priority, the MS SNDCP shall inform MLE that the MS default data priority is "not applicable" using the MLE-CONFIGURE request primitive. If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1), the MS SNDCP should inform MLE that the SNDCP status is "idle" using the MLE-CONFIGURE request primitive.

On reception of an indication that access to the communication resources has become available (on reception of MLE-OPEN indication primitive from MLE), if the MS is not temporarily disabled, the MS SNDCP entity shall enter IDLE state. If SNDCP is temporarily disabled, the MS SNDCP shall remain in the CLOSED state.

If SNDCP receives an MLE-ENABLE indication primitive, the MS SNDCP shall record that it is no longer temporarily disabled. Then, if SNDCP has previously received an MLE-OPEN indication primitive while in the CLOSED state, the MS SNDCP entity shall enter IDLE. If SNDCP has not received an MLE-OPEN indication primitive since it entered the CLOSED state, it shall remain in the CLOSED state.

#### 28.2.4.2 IDLE

In IDLE state the MS and SwMI shall not have PDP contexts. When entering to state IDLE, the STANDBY, RESPONSE\_WAIT, READY, and CONTEXT\_READY timers are stopped. If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1), MLE should be informed that the SNDCP status is "idle" (using the MLE-CONFIGURE request primitive).

Data transfer to and from the mobile subscriber is not possible. The MS is seen as not reachable in this case for TETRA Packet data.

In order to establish SNDCP contexts in the MS and the SwMI, the MS shall perform the PDP context activation procedure. After successful PDP context activation the MS shall start STANDBY timer and enter to state STANDBY.

On reception of an MLE-BREAK indication primitive from the MLE, the MS SNDCP entity shall enter IDLE-Temporary Break state.

#### 28.2.4.3 IDLE-temporary break

IDLE-Temporary Break state is only valid for the MS. This state is only entered while access to the communication resources has become temporarily unavailable (e.g. due to cell reselection). A temporary break in access to the communication resources is signalled to SNDCP by reception of the MLE-BREAK indication primitive from the MLE.

Network selection and initial cell selection and reselection processes are performed by the MS based on V+D procedures. The criteria to select a new cell should also contain weight for advanced link support in the cell.

This state shall be entered from IDLE state on reception of an MLE-BREAK indication primitive. This state shall also be entered from STANDBY-Temporary Break state when the STANDBY timer expires. On entering this state from STANDBY-Temporary Break, all PDP contexts shall be locally deactivated.

In IDLE-Temporary Break state the MS and SwMI shall not have PDP contexts.

Communication between the MS and SwMI SNDCP entities is not possible in this state.

On reception of an MLE-RESUME indication primitive from the MLE, the MS SNDCP entity shall enter IDLE state.

#### 28.2.4.4 STANDBY

In STANDBY state, the subscriber has at least one PDP context activated.

The MS may receive and respond to SN-PAGE REQUEST PDUs while in this state.

The MS may initiate activation of a new PDP context while in STANDBY state.

The MS and SwMI may initiate modification of PDP contexts while in STANDBY state.

The MS may initiate activation of an already-activated PDP context while in STANDBY state as an alternative method of modifying the PDP context; however if the reactivation fails, the PDP context is deactivated and no longer available for use until a successful activation has been performed.

If SNDCP is in the STANDBY state and the MS supports the use of non-conforming PDCHs (see clause 18.4.4.9.1) the MS SNDCP should inform the MLE that the SNDCP status is "standing-by" (using the MLE-CONFIGURE request primitive) in advance of transmitting an SN-DATA TRANSMIT REQUEST PDU requesting channel advice (see clause 28.2.5a). The MS MLE uses this information to start searching for suitable non-conforming PDCHs. The method by which the MS SNDCP gives the MS MLE time to locate a suitable non-conforming PDCH before transmitting a SN-DATA TRANSMIT REQUEST PDU requesting channel advice (see clause 18.3.4.9.11) is outside the scope of the present document.

The MS may initiate deactivation of PDP contexts while in STANDBY state. Before deactivation of the last PDP context assigned by the MS to a particular layer 2 logical link, the MS SNDCP entity shall disconnect that logical link using the method described in clause 28.3.4.3. After deactivation of the last PDP context the STANDBY timer is stopped and SNDCP state is changed to IDLE.

If the MS SNDCP has previously informed the MLE that the SNDCP status is "standing-by" or "ready" and the MS no longer expects to transmit or receive packet data in the foreseeable future, the MS SNDCP should inform the MLE that its SNDCP status is now "idle" (using the MLE-CONFIGURE request primitive). The MS MLE may use this information to stop assessing channel classes and monitoring irregular channels. The information should be sent to the MS MLE when SNDCP returns to the IDLE state, but may be sent sooner.

On reception of a SN-DATA request or SN-UNITDATA request primitive from the service user when the SERVICE\_CHANGE timer is inactive, the MS SNDCP entity shall transmit a SN-DATA TRANSMIT REQUEST PDU.

During an alternating voice and data communication, an MS SNDCP that has returned from READY to STANDBY because of READY timer expiry and now wishes to resume transmitting N-PDUs may transmit a SN-DATA TRANSMIT REQUEST PDU if the SERVICE\_CHANGE timer is inactive (see clause 28.3.4.2 item e).

On transmission of a SN-DATA TRANSMIT REQUEST PDU, the MS SNDCP entity shall send an MLE-ACTIVITY request primitive with sleep mode set to "stay alive", start the RESPONSE\_WAIT timer and enter RESPONSE-WAITING state. The STANDBY timer is not stopped on entering RESPONSE-WAITING state. On reception (MS only) or transmission (SwMI only) of a SN-ACTIVATE PDP CONTEXT ACCEPT PDU or a SN-MODIFY PDP CONTEXT RESPONSE PDU the SNDCP entity shall restart the STANDBY timer.

The STANDBY timer is stopped and the SNDCP state is changed to READY on transmission of (SwMI only) or reception of (MS only) SN-DATA TRANSMIT REQUEST PDU. Upon moving to the READY state the MS SNDCP shall issue an MLE-ACTIVITY request primitive with sleep mode set to "stay alive". If the PDU was individually addressed, the MS and SwMI SNDCPs shall each start the READY timer and the MS SNDCP shall, if supported (see clause 28.2.6.2), start a CONTEXT\_READY timer for each PDP context whose NSAPI was given in the SN-DATA TRANSMIT REQUEST PDU. The SwMI SNDCP may also start CONTEXT\_READY timers (see clause 28.2.6.2). Where the MS receives a group addressed SN-DATA TRANSMIT REQUEST PDU, on moving to READY state the MS shall not start the READY timer or a CONTEXT\_READY timer. (The READY timer and the CONTEXT\_READY timer are not activated when a MS enters READY state for reception of point to multipoint packet data) If data priority is supported by both MS and SwMI on the current cell, and the MS SNDCP wishes to make use of data priority (see clause 28.3.5.5), the MS SNDCP should inform MLE of the MS default data priority when it enters READY state using the MLE-CONFIGURE request primitive. If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1), the MS SNDCP should inform MLE that the SNDCP status is "ready" using the MLE-CONFIGURE request primitive, and should inform MLE of the most demanding data class of those NSAPIs in active use using the MLE-CONFIGURE request primitive, so that MLE can use the MS's currently most demanding data class when determining any reliability adjustment to the present assigned channel replacement threshold (see clause 18.3.4.9.9.1).

On transmission of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1 (i.e. Request accepted), the SwMI SNDCP entity shall stop the STANDBY timer, start the READY timer and enter READY state.

On transmission of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0 (i.e. Request rejected), the SwMI SNDCP entity shall remain in STANDBY state.

On reception of an SN-UNITDATA PDU, the MS SNDCP shall enter the READY state and, if the PDU was individually addressed, shall start the READY timer and, if supported, a CONTEXT\_READY timer. (The SwMI SNDCP starts READY timer and, if used, the CONTEXT\_READY timer on transmission of the PDU.) If the PDU was group addressed, the MS SNDCP shall not start the READY timer or a CONTEXT\_READY timer on entering the READY state. In either case, the MS SNDCP shall issue an MLE-ACTIVITY request primitive with sleep mode set to "stay alive".

During an alternating voice and data communication, an MS that returns from READY to STANDBY because of READY timer expiry during the voice call and now wishes to resume the interrupted PDCH communication but has no data to send may transmit an SN-RECONNECT PDU with "Data to Send" = 0 and remain in the STANDBY state (see clause 28.3.4.2 item e).

If the STANDBY timer expires, the PDP contexts in the SwMI and in the MS are deleted independently and the SNDCP state is changed to IDLE. The SNDCP entity shall issue a SN-NSAPI DEALLOC indication primitive to the service user having "Deactivation type" parameter set to value "Deactivate all NSAPIs". If the MS supports the use of non-conforming PDCHs, the MS SNDCP informs MLE that the SNDCP status is now "idle" (using the MLE-CONFIGURE request primitive).

Where there is a temporary break in access to the radio communication resources as indicated by the reception of an MLE-BREAK indication primitive from the MLE, the MS SNDCP entity shall issue MLE-RELEASE request primitives asking MLE to locally disconnect the advanced links and shall enter STANDBY-Temporary Break state.

If the MS SNDCP entity has an active SERVICE\_CHANGE timer and it receives a SN-DATA request or SN-UNITDATA request primitive from the service user, it shall delay the transmission of a SN-DATA TRANSMIT REQUEST PDU and keep the SN-DATA request or SN-UNITDATA request primitive in its buffers. If the SERVICE\_CHANGE timer expires, the MS SNDCP entity may continue normal operation and transmit a SN-DATA TRANSMIT REQUEST PDU if necessary.

NOTE: The MS SNDCP entity should handle other service requests normally regardless of active SERVICE\_CHANGE timer.

#### 28.2.4.5 STANDBY-temporary break

STANDBY-Temporary Break state is only valid for the MS. This state is only entered while access to the communication resources has become temporarily unavailable (e.g. due to cell reselection). A temporary break in access to the communication resources is signalled to SNDCP by reception of the MLE-BREAK indication primitive from the MLE.

Network selection and initial cell selection and reselection processes are performed by the MS based on V+D procedures. The criteria to select a new cell should also contain weight for advanced link support in the cell.

This state shall be entered from STANDBY state and RESPONSE-WAITING state on reception of an MLE-BREAK indication primitive. This state shall also be entered from READY-Temporary Break state when the READY timer expires.

Communication between the MS and SwMI SNDCP entities is not possible in this state.

On reception of an MLE-RESUME indication primitive from the MLE, the MS SNDCP entity shall enter STANDBY state. In case the MNI values in the MLE-RESUME indication primitive do not match with ones in the MLE-OPEN indication primitive, the MS knows that it has changed the network. Therefore it shall enter the IDLE state and may attempt to reactivate the existing PDP contexts by sending SN-ACTIVATE PDP CONTEXT DEMAND PDUs to the SwMI after state transition, otherwise all contexts shall be deactivated locally. After successful PDP context activation the MS shall start the STANDBY timer and enter to state STANDBY.

If the STANDBY timer expires, the PDP contexts are deleted locally and the SNDCP state is changed to IDLE-Temporary Break. The SNDCP entity shall issue a SN-NSAPI DEALLOC indication primitive to the service user having "Deactivation type" parameter set to value "Deactivate all NSAPIs". If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1), the MS SNDCP should inform MLE that the SNDCP status is now "idle" (using the MLE-CONFIGURE request primitive).

#### 28.2.4.6 RESPONSE-WAITING

RESPONSE-WAITING state is only valid for the MS. In RESPONSE-WAITING state, the MS has at least one PDP context activated.

The MS SNDCP entity shall enter RESPONSE-WAITING state from STANDBY state on transmission of a SN-DATA TRANSMIT REQUEST PDU. On entering RESPONSE-WAITING state the STANDBY timer remains active and the RESPONSE\_WAIT timer is started.

The MS SNDCP entity shall also enter RESPONSE-WAITING state from READY-Temporary Break state on reception of an MLE-RESUME indication primitive from the MLE if pending SN-DATA request or SN-UNITDATA request primitives from the service user cause the MS to transmit an SN-RECONNECT PDU containing "Data to Send" = 1. In this case the MS stops the READY timer and starts the RESPONSE\_WAIT and STANDBY timers.

The MS shall not initiate the activation or modification of PDP contexts while in RESPONSE-WAITING state. The MS shall not initiate the deactivation of PDP contexts while in RESPONSE-WAITING state. The MS may respond to a SN-PAGE REQUEST while in RESPONSE-WAITING state.

On reception of a SN-DATA request or SN-UNITDATA request primitive from the service user, the MS SNDCP entity shall store the request. If the primitive includes a data priority parameter with higher value than the data priority which the MS indicated to MLE with the SN-DATA TRANSMIT REQUEST PDU for which a response is awaited, the MS SNDCP may transmit a new SN-DATA TRANSMIT REQUEST PDU including the new data priority in the MLE-UNITDATA request primitive. In this case, the RESPONSE\_WAIT timer is restarted.

On reception of a SN-DATA TRANSMIT REQUEST PDU, the MS SNDCP shall stop the STANDBY and RESPONSE\_WAIT timers, start the READY timer and, if supported, the CONTEXT\_READY timers for the indicated PDP contexts, and enter READY state. (The SwMI SNDCP may start CONTEXT\_READY timers on transmission of the PDU - see clause 28.2.6.2.) Where the MS receives a group addressed SN-DATA TRANSMIT REQUEST PDU, on moving to READY state the MS shall not start the READY timer or a CONTEXT-READY timer. Neither the READY timer nor a CONTEXT-READY timer is activated when a MS enters READY state for reception of point to multipoint packet data.

On reception of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1, the MS SNDCP shall stop the STANDBY and RESPONSE\_WAIT timers, start the READY timer and enter READY state. The MS shall also, if supported, start the CONTEXT\_READY timers for the PDP contexts whose NSAPIs were given in the SN-DATA TRANSMIT RESPONSE PDU. (The SwMI SNDCP may start CONTEXT\_READY timers on transmission of this PDU.)

If data priority is supported by both MS and SwMI on the current cell (see clause 28.3.5.5), the MS SNDCP shall inform MLE of the MS default data priority when it enters READY state if it wishes to use data priority, using the MLE-CONFIGURE request primitive.

If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1), the MS SNDCP should inform the MLE that the SNDCP status is "ready" (using the MLE-CONFIGURE request primitive) when it enters the READY state, and should inform MLE of the most demanding data class of the NSAPIs given in the SN-DATA TRANSMIT RESPONSE PDU using the MLE-CONFIGURE request primitive, so that MLE can use the MS's currently most demanding data class when determining any reliability adjustment to the present assigned channel replacement threshold (see clause 18.3.4.9.9.1).

On reception of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0, the MS SNDCP shall:

- send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted";
- stop the RESPONSE\_WAIT timer;
- if the MS SNDCP was awaiting a response to an SN-RECONNECT PDU: issue MLE-RELEASE request primitives instructing MLE to locally disconnect the advanced links;
- enter STANDBY state.

Where the RESPONSE\_WAIT timer expires, the MS SNDCP shall:

- send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted";
- if the MS SNDCP was awaiting a response to an SN-RECONNECT PDU: issue MLE-RELEASE request primitives instructing MLE to locally disconnect the advanced links;
- enter STANDBY state.

Where the STANDBY timer expires, the RESPONSE\_WAIT timer is stopped, all PDP contexts are deleted locally and the SNDSCP state is changed to IDLE. The SNDSCP entity shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted", issue a SN-NSAPI DEALLOC indication primitive to the service user having "Deactivation type" parameter set to value "Deactivate all NSAPIs". If the MS supports the use of non-conforming PDCHs, the MS SNDSCP should inform MLE that the SNDSCP status is now "idle" (using the MLE-CONFIGURE request primitive).

Where there is a temporary break in access to the radio communication resources as indicated by the reception of an MLE-BREAK indication primitive from the MLE, the MS SNDSCP entity shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted", stop the RESPONSE\_WAIT timer and enter STANDBY-Temporary Break state.

Prior to entering states STANDBY, STANDBY-Temporary Break, CLOSED or IDLE from state RESPONSE-WAITING, the MS SNDSCP entity shall ensure that all stored SN-DATA request and SN-UNITDATA request primitives are deleted. For each SN-DATA request or SN-UNITDATA request primitive deleted, a corresponding notification of failure shall be sent to the service user in the form of a SN-DELIVERY indication primitive.

#### 28.2.4.7 READY

In READY state, the subscriber has at least one PDP context activated.

The MS may receive and transmit N-PDUs while in this state.

The MS SNDSCP shall enter READY state on reception of a SN-DATA TRANSMIT REQUEST PDU or of a SN-DATA TRANSMIT RESPONSE PDU (with Accept/Reject = 1) and the MS SNDSCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "stay alive". On entering the READY state, the MS SNDSCP shall stop the RESPONSE\_WAIT and STANDBY timers. If the SN-DATA TRANSMIT REQUEST PDU was individually addressed (but not if it was group addressed), the MS SNDSCP shall start the READY timer and, if supported (see clause 28.2.6.2), CONTEXT\_READY timers for the relevant PDP contexts (i.e. the PDP contexts whose NSAPIs were included in the SN-DATA TRANSMIT REQUEST PDU or SN-DATA TRANSMIT RESPONSE PDU).

The SwMI SNDSCP shall enter READY state on transmission of a SN-DATA TRANSMIT RESPONSE PDU (with Accept/Reject = 1) or of a SN-DATA TRANSMIT REQUEST PDU. On entering READY state, the RESPONSE\_WAIT and STANDBY timers are stopped and the READY timer. The SwMI SNDSCP may start the appropriate CONTEXT\_READY timers on transmission of the PDU (see clause 28.2.6.2).

In the case where the MS enters READY state after reception of a group addressed SN-DATA TRANSMIT REQUEST PDU, the MS shall not start the READY timer or a CONTEXT\_READY timer. Neither the READY timer nor a CONTEXT\_READY timer is activated when a MS enters READY state for reception of point to multipoint packet data.

If data priority is supported by both MS and SwMI on the current cell (see clause 28.3.5.5), the MS SNDSCP should inform layer 2 of the MS default data priority when it enters READY state if it wishes to use data priority, using the MLE-CONFIGURE request primitive. If the MS supports the use of non-conforming PDCHs (see clause 18.3.4.9.1) the MS SNDSCP should inform MLE that the SNDSCP status is "ready" using the MLE-CONFIGURE request primitive.

The READY timer is re-started when a SN-DATA PDU (point-to-point) is successfully transmitted as indicated by the reception of a MLE-REPORT indication primitive and accordingly, the READY timer is re-started when an N-PDU is received. The READY timer is also re-started when a SN-UNITDATA (point-to-point) is sent to the MLE for transmission in an MLE-UNITDATA request primitive. In the case of reception of point to multipoint N-PDUs, the READY timer and CONTEXT-READY timer are not (re)started in the MS.

In addition the SwMI should have some other mechanisms to optimize the usage of the PDCH. Because the transfer delay on the LLC can vary substantially as a function of message length, radio link quality, and other traffic on the PDCH, and because only full N-PDUs are delivered to the SNDSCP, the READY timer does not provide tight control of the stay on the PDCH.

The SwMI may therefore further refine the state transition handling by using the MLE-RECEIVE indication primitive and/or other methods to ensure a timely exit from the READY state (by sending an SN-END OF DATA PDU to the MS). The SwMI may use this indication to optimize the length of the stay on the PDCH and should use this indication to prevent sending SN-END OF DATA PDU while data reception is in progress on the LLC. The optimal procedures for this will depend on SwMI design as well as application behaviour, and is therefore outside the scope of the present document.

If the MS possesses more than one activated PDP context and supports the use of CONTEXT\_READY timers, the MS SNDPCP shall maintain a separate CONTEXT\_READY timer for each activated PDP context. Whenever a SN-DATA PDU or SN-UNITDATA PDU is successfully transmitted (as indicated by the reception of a MLE-REPORT indication primitive), whenever a SN-DATA PDU is received and whenever an individually addressed SN-UNITDATA PDU is received, the CONTEXT\_READY timer for the PDP context addressed by the NSAPI in the PDU shall, if supported, be restarted.

If the MS SNDPCP in the READY state receives SN-DATA request primitives or SN-UNITDATA request primitives referencing PDP contexts with inactive or expired CONTEXT\_READY timers, the MS SNDPCP entity shall, if supported, transmit a SN-DATA TRANSMIT REQUEST PDU containing the NSAPIs of the relevant PDP contexts. This warns the SwMI to expect an increase in data throughput, and gives the SwMI an opportunity to reassign the MS to a more suitable PDCH. The MS SNDPCP should use the MLE-CONFIGURE request primitive to inform MLE of the most demanding data class of those PDP contexts with active CONTEXT\_READY timers and the PDP context indicated in the SN-DATA TRANSMIT REQUEST PDU.

NOTE 1: The real-time data class is more demanding than the telemetry data class, and the telemetry data class is more demanding than the background data class.

After transmitting an SN-DATA TRANSMIT REQUEST PDU in the READY state, the MS SNDPCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "stay alive", shall start (or restart) the RESPONSE\_WAIT timer and remain in the READY state. It shall not transmit any SN-DATA or SN-UNITDATA PDUs referencing an NSAPI included in the SN-DATA TRANSMIT REQUEST PDU until it receives an SN-DATA TRANSMIT RESPONSE PDU referencing that NSAPI with Accept/Reject = 1.

On receiving an SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1 referencing waiting NSAPIs, the MS SNDPCP shall stop the RESPONSE\_WAIT timer, shall set up new advanced links if required, and shall commence transmitting SN-DATA PDUs or SN-UNITDATA PDUs for those NSAPIs. (The MS SNDPCP should support the ability to maintain multiple RESPONSE\_WAIT timers in the READY state if it supports sending parallel SN-DATA TRANSMIT REQUEST PDUs for different PDP contexts.)

On reception of an SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0, or if the RESPONSE\_WAIT timer expires, the MS SNDPCP shall stop the RESPONSE\_WAIT timer and remain in the READY state. The MS SNDPCP entity shall ensure that all stored SN-DATA request and SN-UNITDATA request primitives relating to the relevant PDP context are deleted. For each SN-DATA request and SN-UNITDATA request primitive deleted, a corresponding notification of failure shall be sent to the service user in the form of a SN-DELIVERY indication primitive.

The MS shall not deactivate PDP contexts while in READY state. To initiate the deactivation of one or more PDP contexts, a MS returns to STANDBY state. On reception of the SN-NSAPI-DEALLOC request primitive from the SNDPCP service user requesting deactivation of all NSAPIs with active CONTEXT-READY timers, the MS SNDPCP entity may attempt to return to STANDBY state prior to the expiry of the READY timer by sending a SN-END OF DATA PDU to the SwMI. The SwMI shall respond to the SN-END OF DATA PDU with a SN-END OF DATA PDU (unless the MS included an "immediate service change" indication, in which case the MS shall return to the STANDBY state immediately after sending the SN-END OF DATA PDU). See clause 28.3.4.

NOTE 2: If the MS does not get any response to the SN-END OF DATA PDU from the SwMI after a number of retransmissions and restarts of READY timer, it may return independently to the STANDBY state even before inactivity time-out on assigned SCCH. The number of used retransmissions is an implementation dependent issue and is out of the scope of the present document.

NOTE 3: The MS may also return independently to the STANDBY state without any SN-END OF DATA PDU response if the packet data service is overridden by some other service and the channel change to other channel is needed to do immediately (e.g. in case of emergency service). However, the MS should then send a SN-END OF DATA PDU to the SwMI before the state transition and use the "immediate service change" information element to indicate that an immediate service change has occurred and therefore the MS has left the PDCH. An SN-END OF DATA PDU indicating "immediate service change" may be sent on the PDCH, some other allocated channel or a common control channel.

The MS may initiate activation of a new PDP context while in READY state. The MS may also initiate modification of PDP contexts while in this state. Should either happen, the MS shall remain in the state READY.

The MS may initiate activation of an already-activated PDP context while in READY state as an alternative method of modifying the PDP context; however if the reactivation fails, the PDP context is deactivated and no longer available for use until a successful activation has been performed.

Except during cell change or following loss of radio resources, the MS SNDCP remains in the READY state while the READY timer is active even when there is no data being communicated.

When a CONTEXT\_READY timer expires, the MS SNDCP should inform MLE of the most demanding data class of any remaining PDP contexts with active CONTEXT\_READY timers, using the data class information parameter of MLE-CONFIGURE request primitive.

If the READY timer expires in the MS when the MS SNDCP is in the READY state, the MS shall send SN-END OF DATA PDU to the SwMI and shall restart the READY timer.

When the READY timer expires in the SwMI, the SwMI shall send an SN-END OF DATA PDU to the MS. The SwMI shall also send an SN-END OF DATA PDU in response to reception of an SN-END OF DATA PDU from the MS that does not indicate "immediate service change". The SwMI should not send an SN-END OF DATA PDU in response to reception of an SN-END OF DATA PDU that indicates "immediate service change".

The MS SNDCP shall stop the READY timer, stop all active CONTEXT\_READY timers, send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted", start the STANDBY timer and enter to state STANDBY on receiving an SN-END OF DATA PDU, unless the SN-END OF DATA PDU is group addressed and the READY timer is active. The SwMI SNDCP shall enter to state STANDBY when sending an individually addressed SN-END OF DATA PDU.

In the case where an MS with an active READY timer receives a group addressed SN-END OF DATA PDU, the MS shall remain in the READY state with the READY timer still active; if, in this same case, the SN-END OF DATA PDU is accompanied by a "channel change response required" parameter set to "true", the MS shall issue an MLE-CONFIGURE request primitive containing a "channel change accepted" parameter set to "ignore".

If the MS supports data priority, the MS SNDCP shall inform MLE that the MS default data priority is "not applicable" when it exits the READY state, using the MLE-CONFIGURE request primitive. The MS should inform MLE that the SNDCP status is "standing by" when it exits the READY state if the MS supports the use of non-conforming PDCHs.

NOTE 4: An active READY timer normally implies that the MS is on the PDCH and involved in point to point packet data exchanges. Hence the MS in such a case may not wish to leave the READY state.

An MS SNDCP that is in the READY state with an inactive READY timer (i.e. waiting to receive group addressed SN-UNITDATA PDUs) should have a means of returning to the STANDBY state after at least 120 s have elapsed without reception of an SN-UNITDATA PDU or an SN-END OF DATA PDU.

When a SwMI is required by this specification to respond to a SN-END OF DATA PDU received from a MS by sending another SN-END OF DATA PDU to the MS, the SwMI may delay sending the SN-END OF DATA PDU until any outstanding data being prepared for transmission on the downlink, has been transmitted if the MS has not indicated immediate service change in the SN-END OF DATA PDU.

NOTE 5: This delay is required due to the MS SNDCP entity having no knowledge of the status of the LLC entity i.e. if it is currently receiving advanced link segments from the SwMI. Hence the MS SNDCP entity may be unaware that the lower layers are currently receiving packet data.

If the MS indicates "immediate service change" in an SN-END OF DATA PDU (see clause 28.3.4), the SwMI shall cancel the downlink data transmission immediately and enter to state STANDBY.

NOTE 6: If "immediate service change" is indicated by the MS, it does not have to wait for an SN-END OF DATA PDU response from the SwMI before entering to state STANDBY. However, the layer 2 acknowledgement to the SN-END OF DATA PDU sending should be expected before any state transition.

If the SwMI indicates "immediate service change" in an SN-END OF DATA PDU, the MS SNDCP entity should stop the READY timer and any CONTEXT\_READY timers, start the STANDBY timer and SERVICE\_CHANGE timer and enter to state STANDBY and, if data priority is supported by the MS, the MS SNDCP shall inform MLE that the MS default data priority is "not applicable" using the MLE-CONFIGURE request primitive. If the MS supports the use of non-conforming PDCHs, the MS SNDCP should inform the MLE that the SNDCP status is "standing-by" (using the MLE-CONFIGURE request primitive) when it exits the READY state.

NOTE 7: The SwMI should indicate "immediate service change" only if it is going to send a request to another service to the MS which is capable to handle only one active service at the time. When new service is accepted in this case, the exact SNDCP functioning is outside the scope of the present document.

Where there is a temporary break in access to the radio communication resources as indicated by the reception of an MLE-BREAK indication primitive from the MLE, the MS SNDCP entity shall enter READY-temporary break state and, if data priority is supported by the MS, the MS SNDCP shall inform MLE that the MS default data priority is "not applicable" using the MLE-CONFIGURE request primitive. If the MS supports the use of non-conforming PDCHs, the MS SNDCP shall inform the MLE that the SNDCP status is "standing-by" (using the MLE-CONFIGURE request primitive).

Where there is a failure of the PDCH as indicated by reception of an MLE-CONFIGURE indication primitive from the MS MLE indicating "loss of radio resources", the MS SNDCP shall respond as described in clause 28.3.4.7.

The SwMI SNDCP entity shall stop the READY timer and any CONTEXT\_READY timers, start the STANDBY timer and enter STANDBY state on reception of the SN-RECONNECT PDU.

Upon moving to the STANDBY state the MS SNDCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted".

#### 28.2.4.8 READY-temporary break

READY-Temporary Break state is only valid for the MS. This state shall be entered only from the READY state and only when access to the communication resources has become temporarily unavailable (e.g. due to cell reselection or loss of radio resource). A temporary break in access to the communication resources is signalled to SNDCP by reception of the MLE-BREAK indication primitive or MLE-CONFIGURE indication primitive indicating "loss of radio resources" from the MLE.

Communication between the MS and SwMI SNDCP entities may not be possible in this state.

While in the READY-temporary break state, the MS SNDCP shall not attempt to transmit SN-DATA or SN-UNITDATA PDUs.

NOTE 1: When the MS SNDCP is in the READY-temporary break state, the MS should suspend transmission of N-PDUs, including any partially sent or unacknowledged N-PDUs in the LLC buffers, until the MS SNDCP returns to the READY state.

On reception of an MLE-RESUME indication primitive from the MLE, the MS SNDCP entity shall first check if it has a pending SN-DATA request or SN-UNITDATA request primitive. If there is data awaiting transmission, or if the MS wishes to be on a PDCH because it expects imminent reception of data on the downlink or imminent arrival of data for transmission on the uplink, then the MS SNDCP entity shall send to the SwMI a SN-RECONNECT PDU with the field "Data to Send" set to 1 for each NSAPI with data to send or for which downlink or uplink data is imminently expected. The PDU should include the NSAPIs of all PDP contexts for which the MS has active CONTEXT\_READY timers. Where the MS supports advanced link roaming (see clause 28.3.4.4) and where the SNDCP entity is aware that a partially transmitted TL-SDU is in the LLC buffers (i.e. one which has not yet been fully transmitted or one for which an acknowledgement has not yet been received from the peer entity), then the MS shall also set the field "Data to Send" to 1. It shall then stop the READY timer and any CONTEXT\_READY timers, shall start the STANDBY and RESPONSE\_WAIT timers and enter RESPONSE-WAITING state.

If there is no data awaiting transmission, then MS SNDCP entity shall send to the SwMI a SN-RECONNECT PDU with the field "Data to Send" set to 0. It shall then stop the READY timer, start the STANDBY timer and enter STANDBY state.

If the MNI values in the MLE-RESUME indication primitive do not match with the ones in the MLE-OPEN indication primitive, the MS knows that it has changed the network and it shall enter the IDLE state. If the MS supports the use of non-conforming PDCHs, the MS SNDCP should inform MLE that the SNDCP status is "idle" using the ML-CONFIGURE request primitive. The MS shall stop the READY timer and any CONTEXT\_READY timers and may attempt to reactivate the existing PDP contexts by sending SN-ACTIVATE PDP CONTEXT DEMAND PDUs to the SwMI after state transition, otherwise it shall deactivate all contexts locally. After successful PDP context activation the MS shall start the STANDBY timer and enter STANDBY state.

On reception of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1, the MS SNDCP shall stop the RESPONSE\_WAIT timer, start the READY timer and, if supported, the CONTEXT\_READY timers for the indicated PDP contexts and shall enter the READY state. If data priority is supported by both MS and SwMI on the current cell (see clause 28.3.5.5), the MS SNDCP should inform MLE of the MS default data priority when it enters the READY state if it wishes to use data priority, using the MLE-CONFIGURE request primitive.

On reception of an SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0, the MS SNDCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted", stop the RESPONSE\_WAIT timer, the READY timer and any CONTEXT\_READY timers, start the STANDBY timer and shall enter the STANDBY state.

On reception of an SN-DATA TRANSMIT REQUEST PDU, the MS SNDCP shall stop the RESPONSE\_WAIT timer, start the READY timer and, if supported, the CONTEXT-READY timers for the indicated PDP contexts, and shall enter the READY state. Where the MS receives a group addressed SN-DATA TRANSMIT REQUEST PDU, on moving to READY state the MS shall not start the READY timer or a CONTEXT-READY timer. Neither the READY timer nor a CONTEXT-READY timer is activated when a MS enters READY state for reception of point to multipoint packet data.

Where the RESPONSE\_WAIT timer expires, the MS SNDCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted", start the STANDBY timer, shall stop the READY timer and any CONTEXT\_READY timers and shall enter the STANDBY state.

On reception of an MLE-BREAK indication primitive, the MS SNDCP shall stop the RESPONSE\_WAIT timer.

When the READY timer expires, the MS SNDCP entity shall enter STANDBY-Temporary Break state and shall start the STANDBY timer.

NOTE 2: The READY timer does not expire while the RESPONSE\_WAIT timer is active.

Upon moving to the STANDBY, STANDBY-temporary break or IDLE states the MS SNDCP shall send an MLE-ACTIVITY request primitive with sleep mode set to "sleep permitted".

### 28.2.5 State transitions and functions

The movement from one state to the next is dependent on the current state and the triggering event. Figures 28.5 and 28.6 show the state transition diagrams for the MS and SwMI SMDCP entities respectively.

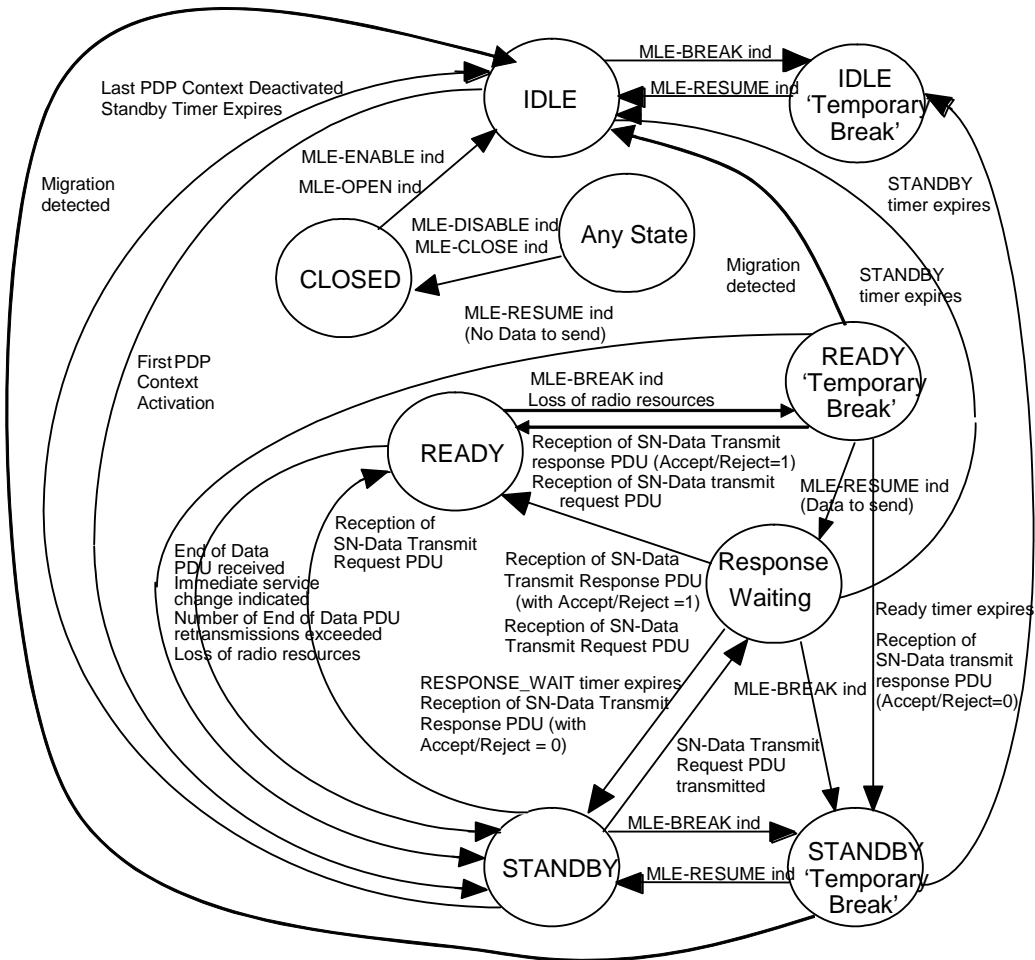

Figure 28.5: Functional SMDCP State Transition Model for MS

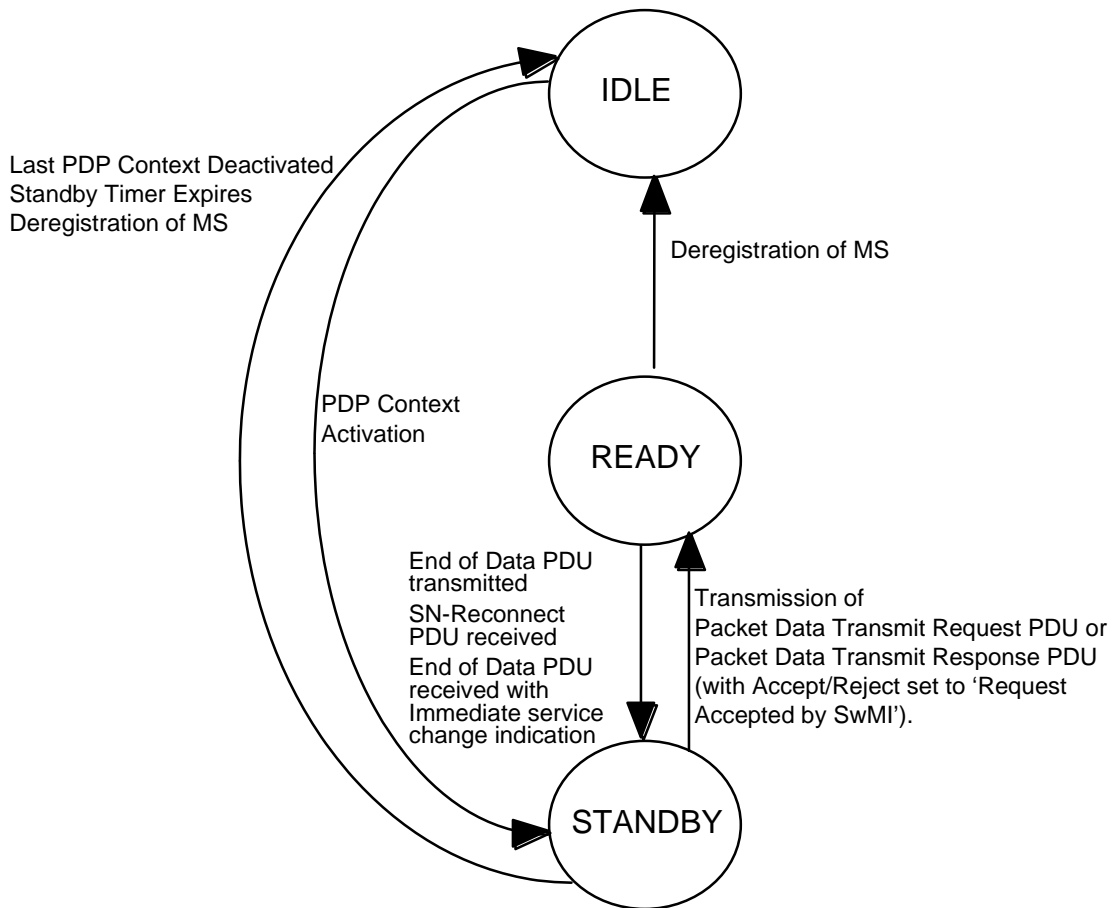

Figure 28.6: Functional SNDCP State Transition Model for SwMI

Tables 28.12 and 28.13 provide a summary of the triggers which shall result in a state transition, the principle actions which are performed and the new state which is entered.

**Table 28.12: MS State Transition Table**

| Current State      | Event   | Principle Actions   | New State          |
|--------------------|---|---|--------------------|
| Any State          | MLE-CLOSE indication primitive or MLE-DISABLE indication primitive received                                     | Stop STANDBY, READY, CONTEXT_READY and RESPONSE_WAIT timers.<br>Fail all pending SN-DATA and SN-UNITDATA request primitives<br>Delete all PDP contexts<br>If sleep is permitted send MLE-ACTIVITY request primitive "sleep permitted".<br>If MLE-DISABLE received, SMDCP records that it is temporarily disabled. | CLOSED             |
| CLOSED             | MLE-OPEN indication primitive received when SMDCP is not temporarily disabled.                                  |   | IDLE               |
| IDLE               | MLE-BREAK indication primitive received   |   | IDLE Temp Break    |
|                    | First PDP Context Activation  | Start STANDBY timer   | STANDBY            |
| IDLE-Temp Break    | MLE-RESUME indication primitive received  |   | IDLE               |
| STANDBY            | Last PDP Context Deactivated  | Stop STANDBY timer  | IDLE               |
|                    | STANDBY timer expires   | Delete all PDP contexts   | IDLE               |
|                    | Receive SN-DATA TRANSMIT REQUEST PDU  | Stop STANDBY timer<br>Start READY and CONTEXT_READY timers<br>Send MLE-ACTIVITY request primitive "stay alive"  | READY              |
|                    | Receive SN-DATA or SN-UNITDATA request primitive and SERVICE_CHANGE timer is inactive.                          | Transmit SN-DATA TRANSMIT REQUEST PDU<br>Start RESPONSE_WAIT timer<br>Send MLE-ACTIVITY request primitive "stay alive"  | RESPONSE-WAITING   |
|                    | SERVICE_CHANGE timer expires, and an SN-DATA request primitive or an SN-UNITDATA request primitive is buffered. | Transmit SN-DATA TRANSMIT REQUEST PDU<br>Start RESPONSE_WAIT timer<br>Send MLE-ACTIVITY request primitive "stay alive"  | RESPONSE-WAITING   |
|                    | MLE-BREAK indication primitive received   |   | STANDBY Temp Break |
| STANDBY-temp break | MLE-RESUME indication primitive received  |   | STANDBY            |
|                    | MLE-RESUME indication primitive received and according to MNI values the MS has changed the network             | Stop STANDBY timer<br>Delete all PDP contexts   | IDLE               |
|                    | STANDBY timer expires   | Delete all PDP contexts   | IDLE Temp Break    |

| Current State    | Event  | Principle Actions   | New State          |
|------------------|--|---|--------------------|

### 28.2.5a MLE-UNITDATA request primitive

If the MS supports the use of non-conforming PDCHs and the MS SMDCP is transmitting an SN-DATA TRANSMIT REQUEST, an SN-PAGE-RESPONSE or an SN-RECONNECT PDU, the MS SMDCP should set the channel advice flag in the MLE-UNITDATA request primitive containing the PDU to "channel advice requested". For all other PDUs, the MS SMDCP shall set the channel advice flag in the MLE-UNITDATA request primitive to "channel advice not requested".

## 28.2.5b Other MLE primitives

This clause describes other MLE primitives at the LTPD-SAP which are more or less separate from normal SNDCP state transition model.

On reception of an MLE-INFO indication primitive, which indicates that the subscriber class being broadcasted by the SwMI and the subscriber class of the MS do not match in the current cell, the MS SNDCP shall stop the communication with the peer entity totally. However, the SwMI should not offer packet data service to the MS, which subscriber class parameter does not match. This information is relevant also in other SNDCP states where the MS is seen as reachable in this case for TETRA Packet data.

On reception of an MLE-INFO indication primitive which indicates that a subscriber class mismatch exists (see clause 16.4.9) or that the present cell is a not-permitted cell (see clause 18.3.5.1.5) the MS SNDCP shall cease communication with the peer entity.

On reception of an MLE-BUSY indication primitive, the MS SNDCP entity knows that an MM protocol exchange is in progress. Then the MS SNDCP shall stop the communication with the peer entity and cannot continue it until it receives an MLE-IDLE indication primitive.

On reception of an MLE-IDLE indication primitive, the MS SNDCP entity knows that an MM protocol exchange has completed and it may continue its normal function.

On reception of an MLE-CLOSED indication primitive, the MS SNDCP shall enter the CLOSED state.

On reception of an MLE-DISABLE indication primitive, the MS SNDCP shall record that the MS is now temporarily disabled and shall enter the CLOSED state. SNDCP shall remain temporarily disabled through power cycles and through cycles of loss and gain of radio resources until it receives an MLE-ENABLE indication primitive from MLE.

## 28.2.6 STANDBY, READY, CONTEXT\_READY and RESPONSE\_WAIT timer functions

### 28.2.6.1 STANDBY timer function

The purpose of the STANDBY Timer is to work as a fallback timer to delete the PDP contexts when they remain unintentionally undeleted.

The STANDBY timer function maintains the STANDBY timer in the MS and SwMI. When the STANDBY timer expires, the MS and SwMI return to IDLE state (or for the MS only, where the previous state was STANDBY-Temporary Break, then the MS shall enter IDLE-Temporary Break), and the PDP contexts are deleted locally.

The duration of the STANDBY timer is the same in the MS and SwMI. Normally, the length of the STANDBY timer is defined by a default value. The SwMI, and only the SwMI, may change this value dynamically by transmitting a new value in the header part of a PDP context activation PDU (accept).

In the present document, the STANDBY timer shall not be set to 0. If the STANDBY timer is set to all 1s (binary), then the STANDBY timer function is deactivated (i.e. the timer no longer runs and the MS and SwMI remain in STANDBY state).

The STANDBY timer is reset and begins running in the MS in the following circumstances:

- on entering STANDBY state from IDLE state;
- on entering STANDBY state from RESPONSE-WAITING state after reception of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0;
- on entering STANDBY state from READY state after reception of a SN-END OF DATA PDU;
- on entering STANDBY state from READY-Temporary Break state after transmission of a SN-RECONNECT PDU with "Data to Send" = 0;
- on entering RESPONSE-WAITING state from READY-Temporary Break state after transmission of a SN-RECONNECT PDU with "Data to Send" = 1;
- on entering STANDBY-Temporary break state from READY-Temporary Break state.

The STANDBY timer is stopped in the MS in the following circumstances:

- on entering CLOSED state;
- on entering IDLE state from STANDBY state;
- on entering READY state from STANDBY state after reception of a SN-DATA TRANSMIT REQUEST PDU;
- on entering READY state from RESPONSE-WAITING state after reception of a SN-DATA TRANSMIT REQUEST PDU;
- on entering READY state from RESPONSE-WAITING state after reception of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1.

The STANDBY timer is reset and begins running in the SwMI in the following circumstances:

- on entering STANDBY state from IDLE state;
- after transmission of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0;
- on entering STANDBY state from READY state after transmission of a SN-END OF DATA PDU;
- on entering STANDBY state from READY state after reception of a SN-RECONNECT PDU.

The STANDBY timer is stopped in the SwMI in the following circumstances:

- on entering IDLE state from STANDBY state;
- on entering READY state from STANDBY state after transmission of a SN-DATA TRANSMIT REQUEST PDU;
- on entering READY state from STANDBY state after transmission of a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1.

### 28.2.6.2 READY timer and CONTEXT\_READY timer functions

The READY timer function maintains the READY timer in the MS and SwMI. The READY timer may be defined for each MS separately. The READY timer controls, with the help of other potential timers, the time an MS and SwMI remains in READY state after either a SN-DATA, SN-UNITDATA, SN-DATA TRANSMIT REQUEST PDU (SwMI to MS) or SN-DATA TRANSMIT RESPONSE PDU (SwMI to MS) has been transmitted between the MS and SwMI. When the READY timer expires in the MS, the MS shall send SN-END OF DATA PDU to the SwMI and restart READY timer. The MS shall stop the READY timer, start the STANDBY timer and enter to the STANDBY state on receiving SN-END OF DATA PDU. When the READY timer expires in the SwMI, the SwMI shall send a SN-END OF DATA PDU to the MS and enter to the STANDBY state. The SwMI may also send a SN-END OF DATA PDU to the MS for its own reasons.

NOTE 1: It is recommended that Packet Data CHannel (PDCH) releasing is done by the SwMI and the MS PDCH release is used as a fallback method. This means that the SwMI should set its own READY timer to a shorter value than the one sent to the MS in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU.

In the present document, the READY timer shall not be set to 0.

The READY timer is reset and begins running in the MS and SwMI in the following cases:

- every time an SN-DATA PDU has been transmitted successfully (as indicated by reception of a MLE-REPORT indication primitive from the MLE) or received by the MS or SwMI;
- every time an SN-UNITDATA PDU is sent to the MLE in an MLE-UNITDATA request primitive;
- when a SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 1 is transmitted (SwMI only) or received (MS only);
- when a SN-DATA TRANSMIT REQUEST PDU is transmitted (SwMI only) or received (MS only);
- when an MLE-CONNECT confirm or an MLE-CONNECT indication primitive is received from the MLE; and
- when an MLE-RECONNECT confirm or an MLE-RECONNECT indication primitive is received from the MLE.

NOTE 2: In the case where a MS receives a group addressed SN-DATA TRANSMIT REQUEST the MS SNDCP entity does not start the READY timer when entering READY state. The READY timer is not activated when a MS enters READY state for reception of point to multipoint packet data.

NOTE 3: In the case of the SN-DATA TRANSMIT RESPONSE and SN-DATA TRANSMIT REQUEST PDUs, transmitted here means that it has been transmitted over the air interface. Acknowledgement from the peer entity is not required nor awaited.

The READY timer should not expire while the MS is actively transmitting an N-PDU at layer 2. The READY timer shall not expire while the RESPONSE\_WAIT timer or any CONTEXT\_READY timer is active.

NOTE 4: If the READY time runs out while the MS is actively transmitting an N-PDU at layer 2 or while any CONTEXT\_READY timer is active, the READY timer should not announce the timer expiry event to SNDCP until the MS has finished transmitting an N-PDU at layer 2 and the RESPONSE\_WAIT timer and the last CONTEXT\_READY timer has expired. The READY timer should not announce the expiry event at all if the READY timer is reset before it has announced the expiry event.

The CONTEXT\_READY timer function allows the MS SNDCP to advise the SwMI when the MS is in the READY state, but wishes to start transmitting N-PDUs for a quiescent PDP context. (A quiescent PDP context is one which has not transmitted or received N-PDUs since it was activated, or for a period of time greater than the duration of its CONTEXT\_READY timer). This gives the SwMI an opportunity to adjust the radio resources available to the MS to suit the MS's total QoS requirement.

MSs which support the transmission or reception of data through more than one PDP context at the same time shall support the use of CONTEXT\_READY timers.

A SwMI that supports the use of QoS negotiation during PDP context activation may make local use of CONTEXT\_READY timers to track the state of the MS's CONTEXT\_READY timers. A SwMI that uses CONTEXT\_READY timers shall follow the same rules as the MS for management of the READY timer and the CONTEXT\_READY timers.

The SNDCP service user may propose a CONTEXT\_READY timer value to the MS SNDCP in the NSAPI-QoS negotiation parameter of the SN-NSAPI ALLOC request and SN-NSAPI MODIFY request primitives. The MS should then propose this CONTEXT\_READY timer value to the SwMI in the QoS information element during PDP context activation or modification, if QoS negotiation is supported by the MS and the current cell (SwMI support for QoS negotiation is indicated in the MLE-INFO indication primitive). If no value was specified in the SN-NSAPI ALLOC or SN-NSAPI MODIFY request primitive, and QoS negotiation is supported by the MS and the current cell, or if the MS does not support the use of CONTEXT\_READY timers, the MS SNDCP should propose to the SwMI that the value of the CONTEXT\_READY timer should be set to track the READY timer value.

If the MS proposes that the CONTEXT\_READY timer should be set to track the READY timer value, the SwMI shall accept that proposal. If the MS proposes a CONTEXT\_READY timer that does not track the READY timer value and the SwMI uses CONTEXT\_READY timers, the SwMI may accept the proposal (possibly with a modified time period). If the MS proposes a CONTEXT\_READY timer that is longer than the READY timer and the SwMI does not use CONTEXT\_READY timers, the SwMI shall propose a CONTEXT\_READY timer that is less than or equal to the READY timer or that shall track the READY timer.

The CONTEXT\_READY timers shall obtain their values either from the QoS information element of the SN-ACTIVATE PDP CONTEXT ACCEPT and SN-MODIFY PDP CONTEXT RESPONSE PDUs for the relevant PDP context, if included, or shall track the value of the READY timer if the QoS information element was not included.

If a CONTEXT\_READY timer is set to track the READY timer value, it shall be set to the READY timer value included in the SN-ACTIVATE-PDP-CONTEXT ACCEPT PDU most recently sent to that MS (irrespective of the NSAPI in the PDU) each time it is restarted.

NOTE 5: A PDP context to be used for transmission or reception of intermittent data (such as for telemetry class data) may benefit from using a longer CONTEXT\_READY timer than would be required by a PDP context used for background class data.

The CONTEXT\_READY timers for the appropriate PDP contexts, if supported, shall be started or re-started whenever an SN-DATA, SN-DATA TRANSMIT REQUEST PDU (SwMI to MS only) or SN-DATA TRANSMIT RESPONSE PDU (with Accept/Reject = 1) has been transmitted successfully (as indicated by MLE-REPORT indication primitive) or has been received for a non-group address, or when an SN-UNITDATA PDU has been sent to MLE for transmission. The CONTEXT\_READY timer shall not be started or re-started by group-addressed PDUs.

If SNDCP is in the READY state, but a CONTEXT-READY timer is inactive or has expired when the MS SNDCP receives an SN-DATA request or SN-UNITDATA request primitive for that PDP context, the MS SNDCP shall transmit an SN-DATA TRANSMIT REQUEST PDU to the SwMI as an indication that its immediate QoS requirement has changed, start the RESPONSE\_WAIT timer and wait for an SN-DATA TRANSMIT RESPONSE PDU (with Accept/Reject = 1) for the relevant PDP context before transmitting an SN-DATA PDU or SN-UNITDATA PDU for that PDP context.

If the MS SNDCP is in the READY state when it receives an SN-NSAPI MODIFY request primitive from the MS SNDCP service user requesting a PDP context to be paused, the MS SNDCP shall stop the CONTEXT\_READY timer and, if the current cell supports QoS negotiation during PDP context activation, shall notify the SwMI SNDCP that it is pausing use of the PDP context by transmitting an SN-MODIFY PDP CONTEXT USAGE PDU. The SwMI shall stop any CONTEXT\_READY timer for the relevant PDP context when it receives this notification.

All CONTEXT\_READY timers shall be stopped when SNDCP exits the READY state or the MS SNDCP exits the READY temporary break state into some state other than these.

### 28.2.6.3 RESPONSE\_WAIT Timer Function

The RESPONSE\_WAIT timer function maintains the RESPONSE\_WAIT timer in the MS. The duration of the RESPONSE\_WAIT timer is assigned by the SwMI at PDP context activation. The value received from the SwMI in the most recent PDP context activation shall apply to all PDP contexts. The RESPONSE\_WAIT timer controls the time an MS shall await a response from the SwMI to a SN-DATA TRANSMIT REQUEST or SN-RECONNECT PDU and hence the time the MS SNDCP remains in RESPONSE-WAITING state. If a response (in the form of a SN-DATA TRANSMIT RESPONSE) is received before the RESPONSE\_WAIT timer expires, then the MS SNDCP shall leave RESPONSE-WAITING state (if it is in that state) and shall stop the RESPONSE\_WAIT timer. If the MS is in the RESPONSE\_WAITING or READY temporary break state when the RESPONSE\_WAIT timer expires before a response is received, then the MS shall go to the STANDBY state. If the MS is in the READY state when the response is received or when the RESPONSE\_WAIT timer expires, it shall remain in the READY state (this can occur when the MS is attempting to transmit N-PDUs for a quiescent PDP context when busy transmitting or receiving N-PDUs for a different PDP context).

The RESPONSE\_WAIT timer is reset and begins running in the MS when entering RESPONSE-WAITING state.

The RESPONSE\_WAIT timer is stopped in the MS when leaving RESPONSE-WAITING state.

NOTE: The MS SNDCP may support concurrent RESPONSE\_WAIT timers (one per PDP context) in the READY state.

### 28.2.6.4 SERVICE\_CHANGE Timer Function

The SERVICE\_CHANGE timer shall be started by the MS SNDCP when it receives an individually addressed SN-END OF DATA PDU indicating immediate service change. The MS shall then enter the STANDBY state. While the SERVICE\_CHANGE timer remains active the MS shall defer sending the SwMI an SN-DATA TRANSMIT REQUEST PDU (in respect of any pending N-PDUs).

When the SERVICE\_CHANGE timer expires, if the MS SNDCP has any pending N-PDUs it shall send the SwMI an SN-DATA TRANSMIT REQUEST PDU in the normal way, preparatory to sending the pending N-PDUs.

The SERVICE\_CHANGE timer function enables the SwMI to keep the MS SNDCP in the STANDBY state on the common control channel (MCCH or MCCH-Q or common SCCH) for the SERVICE\_CHANGE period of time, even though the MS SNDCP may have pending N-PDUs ready for transmission. This allows the SwMI to complete an exchange of signalling with the MS on the common control channel concerning some other service.

## 28.3 SNDCP Procedures

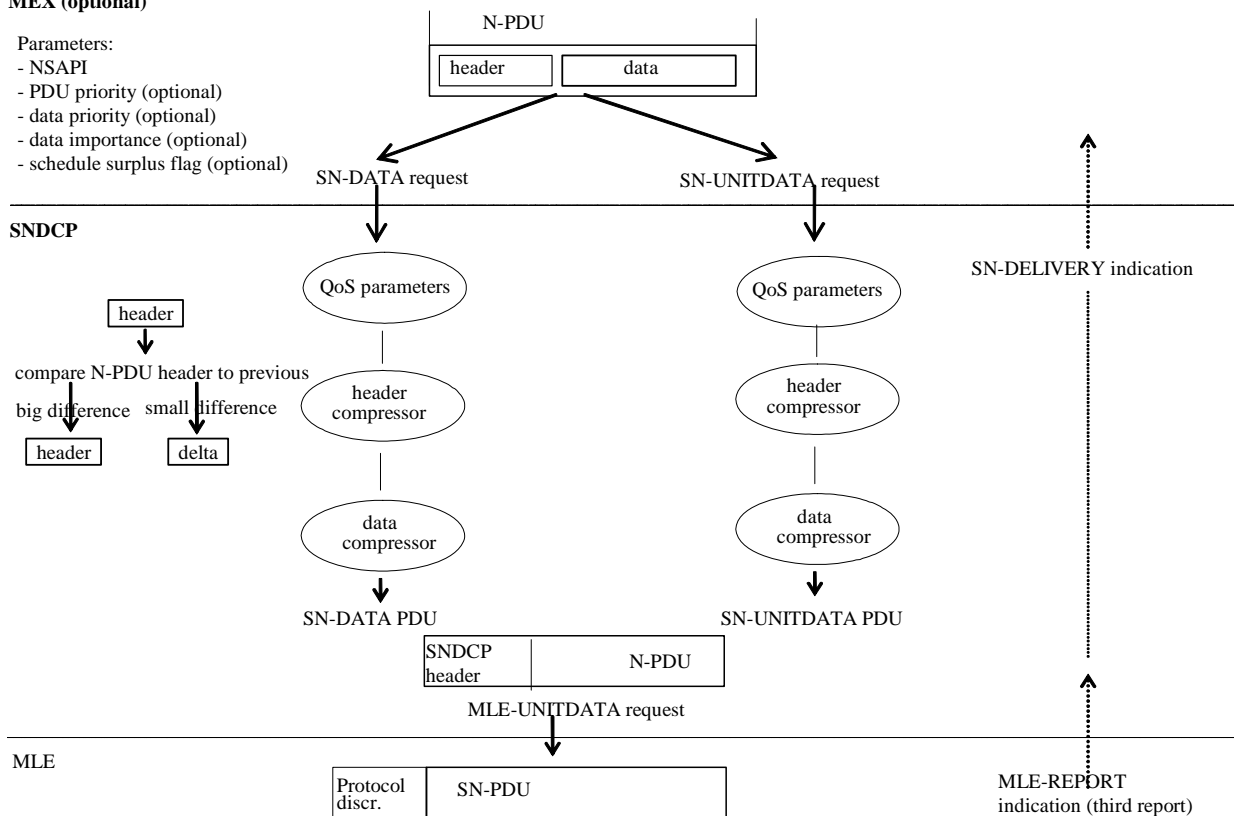

### 28.3.1 Services provided by the protocol

SNDCP performs the following functions (see figures 28.7 and 28.8):

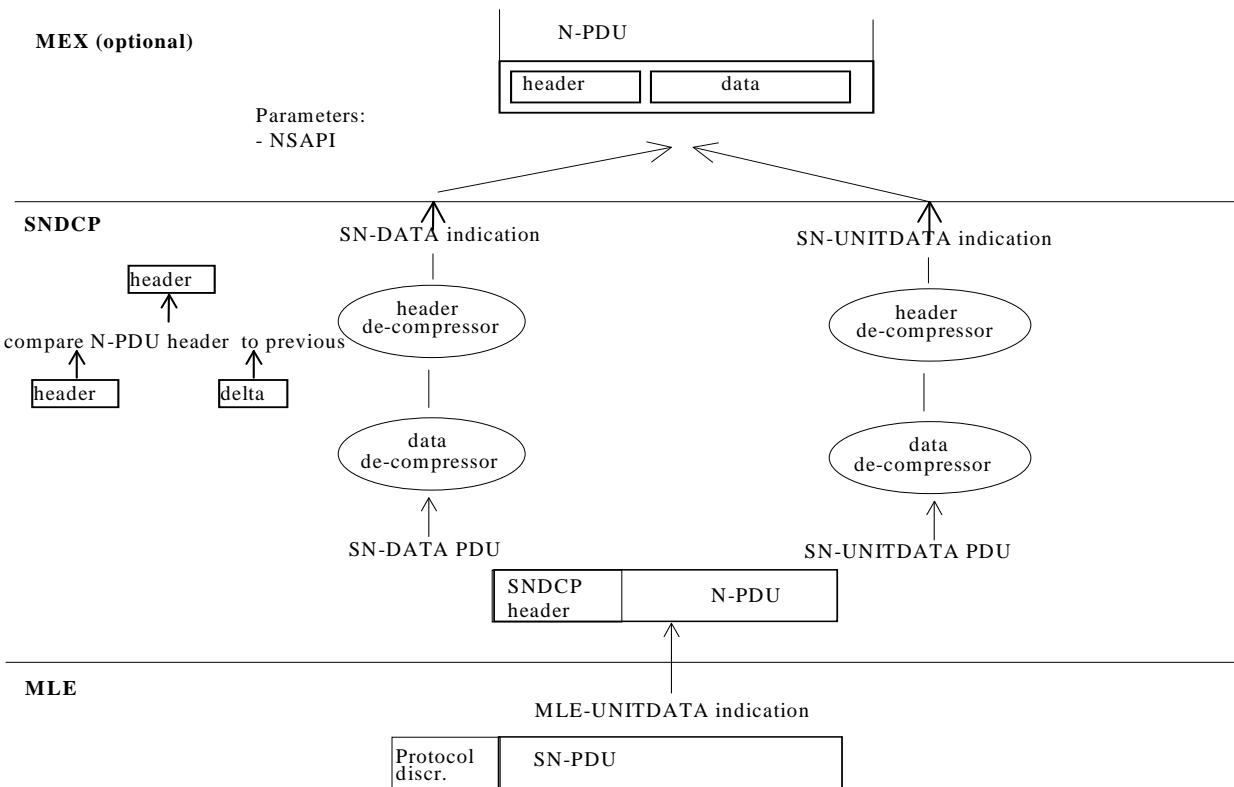

- PDP context activation and PDP context deactivation;
- assignment of layer 2 logical links to activated PDP contexts;
- Packet Data CHannel (PDCH) handling;
- multiplexing of N-PDUs from one or several higher protocol entities onto one or more layer 2 connections;
- mapping of SN primitives received from the network layer into corresponding MLE-UNITDATA request primitives to be passed to the MLE;
- if data priority is not supported by the MS, management of the delivery sequence according to the PDU priority of SN-UNITDATA and SN-DATA request primitives;
- if data priority is supported by the MS:
  - management of the delivery sequence according to the PDU priority and data priority of SN-UNITDATA and SN-DATA request primitives;
  - management of the data priority of N-PDUs;
- compression and recovery of redundant protocol control information (e.g. TCP/IP header). Header compression is performed independently for each NSAPI;
- compression and recovery of redundant user data. Data compression is performed independently for each NSAPI;
- management of application-level QoS requirements.

**MEX (optional)**

- Parameters:  
 - NSAPI  
 - PDU priority (optional)  
 - data priority (optional)  
 - data importance (optional)  
 - schedule surplus flag (optional)

**Figure 28.7: SNDCP model for transmitting end**

**Figure 28.8: SNDCP model for receiver end**

## 28.3.2 Underlying services assumed by the protocol

The following services are expected to be provided by the MLE through the LTPD-SAP:

- acknowledged (MS -> SwMI and SwMI -> MS) and unacknowledged (MS -> SwMI and SwMI -> MS) data transfer; point-to-point (MS -> SwMI and SwMI -> MS) and point-to-multipoint data transfer (SwMI -> MS);
- high reliability data transfer (FCS on, acknowledged), moderate reliability data transfer (FCS off, acknowledged) and low delay (low reliability) data transfer (FCS on or off and unacknowledged);
- PDU priority based transfer of SN-PDUs (eight PDU priority levels);
- if the MS does not support data priority:
  - in-order delivery of SN-PDUs per PDU priority (i.e. SN-PDUs with the same PDU priority have to appear at the receiving end in the same order as transmitted between SNDSCP entities). This is required only for acknowledged service;
- if the MS does support data priority:
  - data-priority based N-PDU access to radio resources (8 data priority levels);
  - in-order delivery of SN-PDUs not containing an N-PDU per PDU priority (i.e. SN-PDUs not containing an N-PDU and having the same PDU priority have to appear at the receiving end in the same order as transmitted between SNDSCP entities). This is required only for acknowledged service;
  - in-order delivery of SN-DATA PDUs per PDU priority and data priority (i.e. SN-DATA PDUs with the same PDU priority and data priority have to appear at the receiving end in the same order as transmitted between SNDSCP entities);
  - in-order transmission of SN-UNITDATA PDUs per PDU priority and data priority (i.e. SN-UNITDATA PDUs with the same PDU priority and data priority have to be transmitted a first time in the same order as sent to MLE by the MS SNDSCP);
- support for variable length SN-PDUs;
- indications about radio link condition (CLOSE, OPEN, BREAK);
- indications about LLC connections (establishment, re-connection, release);
- access to disconnect LLC connections;
- support for regularly scheduled slot grants (scheduled access), including provision of schedule timing indications to the MS SNDSCP.

## 28.3.3 Context activation, modification and deactivation procedures

### 28.3.3.0 General

An MS in IDLE, STANDBY or READY states can initiate PDP context activation functions to establish a virtual data channel i.e. PDP context between the MS and the SwMI. An MS in STANDBY state can initiate PDP context deactivation functions. An MS or SwMI in the STANDBY or READY states can initiate PDP context modification. An MS in the STANDBY or READY state may initiate activation of an already-activated PDP context as an alternative method of modifying the PDP context; however if a reactivation fails, the PDP context is deactivated and is no longer available for use until a successful activation has been performed.

Upon receiving an SN-ACTIVATE PDP CONTEXT DEMAND PDU, the SwMI shall initiate procedures to set up the PDP context.

Upon receiving an SN-MODIFY PDP CONTEXT REQUEST PDU, the SwMI shall, if supported, initiate procedures to modify the PDP context.

Upon receiving an SN-MODIFY PDP CONTEXT REQUEST PDU, the MS shall, if supported, confirm to the SwMI the modification of the PDP context and advise affected applications.

Upon receiving a SN-DEACTIVATE PDP CONTEXT DEMAND PDU, the SwMI shall initiate procedures to delete the PDP context.

Upon receiving a SN-DEACTIVATE PDP CONTEXT DEMAND PDU, the MS shall initiate procedures to delete the PDP context.

A conventional access MS shall not attempt to activate or modify a PDP context while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDCCP service is not available on this cell".

A MS may only attempt to activate one PDP context at a time. Hence a MS after transmitting a SN-ACTIVATE PDP CONTEXT DEMAND PDU shall await the occurrence of one of the following events, before sending a new SN-ACTIVATE PDP CONTEXT DEMAND PDU:

- reception of a SN-ACTIVATE PDP CONTEXT ACCEPT PDU;
- reception of a SN-ACTIVATE PDP CONTEXT REJECT PDU;
- expiration of the PDP\_ACTIVATE\_WAIT timer.

A MS may only have one PDP context modification request outstanding at a time. Hence a MS, after transmitting a SN-MODIFY PDP CONTEXT REQUEST PDU shall await the occurrence of one of the following events before sending a new SN-MODIFY PDP CONTEXT REQUEST PDU:

- reception of a SN-MODIFY PDP CONTEXT RESPONSE PDU with modify type = response;
- expiration of the PDP\_MODIFY\_WAIT timer.

A MS may only have one PDP context deactivation request outstanding at a time. Hence a MS after transmitting a SN-DEACTIVATE PDP CONTEXT DEMAND PDU shall await the occurrence of one of the following events, before sending a new SN-DEACTIVATE PDP CONTEXT DEMAND PDU:

- reception of a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU;
- expiration of the PDP\_DEACTIVATE\_WAIT timer.

An MS shall activate a primary PDP context before it attempts to activate a secondary PDP context linked to that primary PDP context. Primary and secondary PDP context activation requests are indicated by the "address type identifier in demand" information element.

An MS should not request a secondary PDP context unless QoS negotiation is supported by the SwMI.

When a primary PDP context is deactivated, all secondary PDP contexts linked to that primary PDP context shall be locally deactivated.

The SwMI shall not accept a primary PDP context activation request specifying a PDP address already in use by some other PDP context.

A SwMI that supports QoS negotiation during PDP context activation but does not support the use of secondary PDP contexts shall refuse an MS's request for activation of a secondary PDP context with reject cause "Secondary PDP contexts not supported".

### 28.3.3.0a SNDCCP QoS requests

The MS can request two types of QoS. QoS that is requested during advanced link setup is called advanced link QoS. The present clause concerns QoS that is requested during PDP context activation and modification.

The MS requests a particular type of QoS by including the QoS information element in the SN-ACTIVATE PDP CONTEXT DEMAND or SN-MODIFY PDP CONTEXT REQUEST PDU.

The MS shall not send the SwMI a QoS information element unless it knows that the present BS supports QoS negotiation e.g. because the MS has received an indication in a SYSINFO PDU that the present cell supports QoS negotiation or QAM (in an extended services broadcast information element), or because the present cell is a DA cell.

The MS shall not include the QoS information element in its response to an SN-MODIFY PDP CONTEXT REQUEST PDU received from the SwMI.

If the MS does not include a QoS information element in an SN-ACTIVATE PDP CONTEXT DEMAND or SN-MODIFY PDP CONTEXT REQUEST PDU and the SwMI accepts the MS's PDP context activation or modification request, the SwMI shall not include a QoS information element in its response and the MS shall assume that it has been granted a background class QoS with unspecified throughput, reliability and delay.

If the MS sends a QoS information element and the SwMI accepts the MS's PDP context activation or modification request and QoS request, the SwMI may either include the same QoS information element or may omit the the QoS information element in the response accepting the MS's PDP context activation or modification request. If the SwMI does not include a QoS information element in its response, the MS shall assume that its QoS request has been granted in full.

If the SwMI decides to grant a QoS that is different to the QoS requested by the MS, the SwMI shall include a QoS information element in its response.

If the SwMI includes a QoS information element in its response, the MS shall assume that it has been granted exactly the QoS specified by the SwMI's QoS information element. If any QoS item that the MS requested is omitted from the SwMI's QoS information element, the MS shall assume it has not been granted that QoS item. If the SwMI sends a one-bit QoS element in its response, the MS shall assume that it has been granted a background class QoS with unspecified throughput, reliability and delay but no other items that were requested by the MS.

If the MS sends a one-bit QoS information element, the SwMI shall not include a full QoS information element in its response.

If an MS sends a full QoS information element to a SwMI that does not support full QoS information elements and the SwMI accepts the MS's context activation request, the SwMI shall include a one-bit QoS information element in its response.

If the MS requests use or modification of scheduled access and the SwMI is unable to provide the proposed schedule, the SwMI shall respond with an SN-ACTIVATE-PDP CONTEXT REJECT PDU or an SN-MODIFY PDP CONTEXT RESPONSE PDU indicating "modification rejected".

The MS shall not include a QoS filter specification in the QoS element of any PDU relating to a primary PDP context. The SwMI shall reject any PDP context activation or modification request for a primary PDP context that includes a QoS filter specification, using reject cause "QoS filter not available for primary PDP context". See clause 28.3.9 for a description of QoS filters.

### 28.3.3.1 Internet Protocol addressing support

#### 28.3.3.1.1 IPv4 - Static and dynamic IP addresses

A TETRA system can be viewed as a single or multiple IP subnets. A TE which is attached to a MT on a TETRA network, can be viewed as a host on an IP subnet.

In order for IP packets from an external IP network, to reach a data TE which is attached to a MT on a TETRA network, it is necessary for the destination address used in the IP packets to be topologically correct i.e. packets, using standard internet routing procedures, can be forwarded to the TETRA network. The forwarding of packets within the TETRA network is outside of the scope of the present document.

IP addresses can be allocated to an MS in two different ways:

- an IP address is assigned permanently to the MS. The IP address shall be sent to the SwMI when activating PDP context;
- the SwMI assigns a dynamic IP address to the MS when PDP context is activated.

It is the operator that defines in the subscription whether a dynamic IP address can be used.

When dynamic addressing is used, it is the responsibility of the SwMI to allocate and release the dynamic IP address.

### 28.3.3.1.2 Mobile IPv4

Mobile IP allows nodes to move from one IP subnet to another without changing their IP address. A brief overview of Mobile IP is given below so as to help illustrate the addressing concept, however the reader is referred to IETF RFC 5944 [39] for a more complete description of the protocol.

In the description below, the following definitions apply:

- **Mobile Node:** An IP host or router that changes its point of attachment to the internet from one subnet to another.
- **Home address:** Internet protocol address, that is assigned to a Mobile Node for an extended period of time. This address is used by all other nodes when attempting to send IP packets to the Mobile Node. This address remains constant irrespective of the Mobile Nodes point of attachment to the internet.
- **Home network:** A network, having a network prefix matching that of the Mobile Node's home address. Standard IP routing mechanisms ensure that IP packets destined for the Mobile Node's home address are routed via the Mobile Node's home network.
- **Foreign network:** Any network, other than the Mobile Node's home network, i.e. a network which has a network prefix different to that of the Mobile Node's home IP address.
- **Visited Network:** A foreign network to which the Mobile Node is currently connected.
- **Home Agent:** A router on a Mobile Node's home network which tunnels IP packets for delivery to the Mobile Node when it is away from its home network. The Home Agent has similar functionality to the Home Location Register (HLR) in GSM.
- **Foreign Agent:** A router on the Mobile Node's visited network which detunnels and delivers IP packets to the Mobile Node, that were tunneled by the Home Agent.
- **Care-of Address:** The termination point of a tunnel towards a Mobile Node, for IP packets forwarded to the Mobile Node while it is away from its home network. The protocol can use two different types of care-of address: a "foreign agent care-of address" is an address of a foreign agent with which the mobile node is registered, and a "co-located care-of address" is an externally obtained local address which the mobile node has associated with one of its own network interfaces.

A Mobile Node is given a long term IP address on a home network. This IP address is administered in the same way as a "permanent" IP address is provided to a stationary host. When the Mobile Node detects that it is located on its home network, it operates without mobility services.

When a Mobile Node detects that it has moved to a foreign network, it obtains a care-of address on the foreign network. The mobile node then registers its new care-of address with its Home Agent.

IP packets sent to the Mobile Node's home address are intercepted by its Home Agent, tunneled by the Home Agent to the Mobile Node's care-of address, received at the tunnel endpoint (typically the foreign agent), and finally delivered to the mobile node.

In the reverse direction, IP packets sent by the mobile node are generally delivered to their destination using standard IP routing mechanisms, not necessarily passing through the home agent.

The TETRA packet data specification extends a TETRA network to act as one or more IP subnets. A TETRA network may offer Mobile IP services by including Home Agent and/or Foreign Agent functionality. The TETRA packet data specification provides a mechanism by which a Mobile Node may use Mobile IP services where they are available.

As an example, where a TETRA SwMI includes Mobile IP Foreign Agent functionality, a Mobile Node may perform Mobile IP Registration as described in IETF RFC 5944 [39] with its Home Agent (which may be located on a fixed IP subnet) via the SwMI based Foreign Agent. This Foreign Agent shall then act as the tunnel end point for those IP packets forwarded by the Home Agent. The Mobile Node may learn the Foreign Agent Care of Address through the PDP Context Activation procedure.

In TETRA Packet data, a MS shall indicate if it wishes to avail of Mobile IP services in the SN-ACTIVATE PDP CONTEXT DEMAND PDU by setting "Address Type Identifier in Demand" to "Mobile IPv4 Foreign Agent Care-of Address" or "Mobile IPv4 Co-located Care-of Address". A SwMI which offers support for Mobile IP services may respond with a "Mobile IPv4 Care-of Address" plus further information within the information element "SwMI Mobile IPv4 Information" of the SN-ACTIVATE PDP CONTEXT ACCEPT PDU.

### 28.3.3.1.3 IPv6

IPv6 will support two methods for a host to obtain a global IPv6 address. Stateful address autoconfiguration shall enable a host to be dynamically allocated an IP address through the use of a protocol such as Dynamic Host Configuration Protocol (DHCPv6). This will operate in a similar way to dynamic address allocation in IPv4. Stateless address autoconfiguration enables a host to generate its own IP address through information broadcast on the network where it is camped. The IPv6 address is 128 bits compared to 32 bits in IPv4. The address is broken into two parts, the Link Prefix and the Interface Identifier as shown in figure 28.9.

**Figure 28.9: Ipv6 address**

In the case of both address autoconfiguration methods, the IPv6 node first generates a link local IPv6 address. A link-local IPv6 address may only be used on the link or subnet to which the node is connected. To generate a link local address, an IPv6 node combines an Interface-Identifier with the Link Prefix which has been reserved for link local addresses. The IPv6 node will then use this link local IPv6 address to obtain a global IPv6 address. Typically this will involve sending a Router Solicitation and receiving a Router Advertisement.

In TETRA Packet data, a MS indicates in the SN-ACTIVATE PDP CONTEXT DEMAND PDU whether it wishes to use IPv6 services by setting "Address Type Identifier in Demand" appropriately.

Where the SwMI indicates in a SN-ACTIVATE PDP CONTEXT ACCEPT PDU that IPv6 is supported, the MS may then use a link local IPv6 address to perform stateful or stateless address autoconfiguration.

It is recommended that when generating a link local IPv6 address, the MS shall use its ITSI as the 48 least significant bits of the Interface Identifier thus ensuring that the Interface Identifier is unique on the link or subnet. A further requirement for Interface Identifier, is for the 6th most significant bit to be set to zero. All other bits of the Interface Identifier may be set to zero or may be used to support multiple link local addresses per ITSI.

This version of the packet data specification does not specify how IPv6 service is provided by a SwMI or the actions which a MS takes in order to obtain a global IPv6 address. Where a SwMI sends a SN-ACTIVATE PDP CONTEXT ACCEPT PDU indicating that it supports IPv6 services, it is recommended that the SwMI then prepares to receive a Router Solicitation and respond with a Router Advertisement.

### 28.3.3.2 NSAPI usage

The set of protocol entities above SNDCP uses the same SNDCP entity, which then performs multiplexing of data coming from different sources to be sent across a single LLC connection. Sharing a single LLC connection requires that different addresses can be identified. The NSAPI field of four bits is used for this purpose, defining the end user PDP type and PDP address pair that the MS is using. Following values are reserved for special use:

- 0 is reserved;
- 15 is reserved.

NOTE 1: The user application should start from NSAPI value 1 when allocating the first PDP context.

Other values are allocated dynamically. The allocation of the dynamic NSAPIs can be e.g. following:

- IPv4: 133.12.75.111 => NSAPI = 2
- IPv4: 133.12.75.222 => NSAPI = 3

NOTE 2: NSAPI may be used also for routing between MT and TE, e.g. NSAPI = 2 is activated by the TE2 and NSAPI = 3 is activated by the MT (actually MT0 to be exact i.e. the MS may act as MT0 and MT2 at the same time). The MEX layer may be used to provide this routing service (see clause 30.3.7).

NOTE 3: Data arriving in SNDTCP via a secondary PDP context should be routed according to the NSAPI of the primary PDP context.

Since the adaptation of different higher layer protocol to SNDTCP is implementation dependent, it is not defined in the present document.

### 28.3.3.3 SNDTCP network endpoint identifier

Within the SwMI, there may be a requirement for multiple SNDTCP entities in order to provide load balancing or to provide packet data service for different geographical regions. In order to support the existence of multiple such SNDTCP entities within the SwMI, a SNDTCP Network Endpoint Identifier (SNEI) may be assigned to each MS at PDP Context Activation. The SNEI information element shall only be present in uplink communication when the SwMI has assigned a SNEI value to the MS during context activation. Where the MS has been assigned a SNEI value during PDP context activation, then there are four occasions where the MS shall include the SNEI as part of uplink communication:

- 1) When in READY state and after performing a cell change, the MS SNDTCP entity shall include the SNEI as part of the Reconnect message (see clause 28.3.4.2 c) if the BS does not support QAM modulation - the SNEI does not need to be included if the BS supports QAM modulation.
- 2) When requesting permission to transmit data to a BS which does not support QAM modulation, the MS SNDTCP entity shall include the SNEI - the SNEI does not need to be included if the BS supports QAM modulation.
- 3) When responding to a page from the SwMI, the MS SNDTCP entity shall include the SNEI if the BS does not support QAM modulation - the SNEI does not need to be included if the BS supports QAM modulation.
- 4) When deactivating a PDP context, the MS SNDTCP entity shall include the SNEI if BS does not support QAM modulation - the SNEI does not need to be included if the BS supports QAM modulation.

A BS which supports QAM modulation shall have an alternative method of discovering an MS's SNEI.

The SwMI may assign a new SNEI to a MS in any of the following circumstances:

- 1) When activating a new PDP context.
- 2) When responding to a request from a MS to transmit data.
- 3) When paging a MS.

On reception of a new SNEI value, the MS SNDTCP entity should store this value for later use. The value of SNEI which the MS shall send to the SwMI during uplink communication shall be the most recently received SNEI. The SwMI shall only assign one SNEI per ITSI. The most recently received SNEI shall apply to all PDP contexts for a given ITSI.

The usage of the SNEI within the SwMI is outside the scope of the present document.

### 28.3.3.4 Definition of Packet data MS Types

#### 28.3.3.4.0 General

The following clauses 28.3.3.4.1 to 28.3.3.4.4 describe the service interactions between circuit mode, messaging and packet data services as defined by the value of the Packet data MS Type information element. The types have meaning only in the context of TETRA Packet data. It is used by the MS to indicate to the SwMI its service interaction capabilities between packet data and individual circuit mode speech and data calls. The Packet data MS Type is sent to the SwMI when activating PDP context. If the Packet data MS Type is changed after the first PDP context activation, then the SwMI shall use the Packet data MS Type value, as received in the latest PDP activation.

NOTE 1: If the SwMI rejects a PDP context activation with the Activation reject cause set as "Packet Data MS type not supported" the MS may retry the PDP context activation with a lower Packet Data MS type e.g. if the SwMI rejects a Packet Data MS type of A the MS may try to activate a context as a Packet Data MS type of B, C or D. How the MS determines which Packet Data MS type to choose following a PDP context activation rejection is outside the scope of the present document.

The SwMI may use the Packet data MS type value to assist in optimizing air interface signalling when offering packet data services to an MS. For example the SwMI may choose not to offer (because the MS will probably not accept):

- TETRA Packet data to type D and C MS which is engaged in a circuit mode speech/data;
- Circuit mode speech/data to type D and C MS which is engaged in TETRA Packet data.

NOTE 2: If the MS is offered a circuit mode service, it may choose to ignore, reject or accept the service. The criteria for the MS to ignore, reject or accept the service are outside the scope of the present document.

In addition SwMI should be aware that type B MS shall abandon TETRA Packet data temporarily if it accepts or initiates circuit mode speech/data and vice versa. Type A MS may preserve both services parallel.

NOTE 3: SN-NSAPI ALLOC request primitive does not contain MS TETRA Packet data Type as a parameter. This is because the type may be constrained by the capabilities of the MS.

NOTE 4: An MS should always be capable of making an emergency call set up irrespective of the packet data MS Type and packet data state.

NOTE 5: How the SwMI determines the circuit mode status of an MS is outside the scope of the present document.

NOTE 6: The SwMI can only optimize the air interface signalling when interacting with individual calls. Interaction with group calls and Supplementary Services is outside the scope of the present document.

The different types for TETRA Packet data MSs and their capabilities to handle other services in addition to TETRA Packet data are summarized in table 28.14.

**Table 28.14: Packet data MS types and other services**

| Service   | Type A | Type B | Type C | Type D |
|---|--------|--------|--------|--------|
| Circuit mode speech/data conducted in READY state   | X      |        |        |        |
| Circuit mode speech/data set up in READY state      | X      | X      |        |        |
| SDS in READY state                                  | X      | X      | X      |        |
| Circuit mode speech/data conducted in STANDBY state | X      | X      | X      | X      |
| TETRA Packet Data                                   | X      | X      | X      | X      |

#### 28.3.3.4.1 Type A - Parallel

All services (SDS, Circuit mode speech/data) may be conducted parallel with TETRA Packet data. MS has the capability to receive/send both circuit mode speech/data and TETRA Packet data at the same time. This means that circuit mode speech/data may be set up, accepted and conducted while the MS is in READY state. SDS may be conducted while the MS is in READY state.

NOTE: This MS can only support concurrent Packet data and circuit mode if the appropriate resources matching the "Class of MS" (refer to clause 16.10.5) can be allocated by the SwMI.

### 28.3.3.4.2 Type B - Alternating

Other services (SDS, Circuit mode speech/data) may be conducted alternating with TETRA Packet data, i.e. if MS is engaged in TETRA Packet data it may accept circuit mode speech/data and vice versa but only one service (TETRA Packet data or circuit mode speech/data) can be active at any time. SDS can be conducted parallel both with TETRA Packet data and circuit mode speech/data. This means that circuit mode speech/data may be set up but not conducted while the MS is in READY state. Circuit mode speech/data may be only conducted in STANDBY state.

### 28.3.3.4.3 Type C - IP single mode

The MS is engaged to one service at a time; if MS is engaged in TETRA Packet data it does not accept circuit mode speech/data and vice versa:

- 1) While the MS is in the READY state i.e. engaged in TETRA Packet Data, no circuit mode speech/data calls may be set up, accepted or conducted. However, SDS may be conducted while the MS is in the READY state.
- 2) While the MS has an ongoing circuit mode speech/data call or is in the call set up phase, TETRA Packet data is not allowed (accepted or initiated). This means that circuit mode speech/data may be set up, accepted or conducted while the MS is in STANDBY state. SDS may also be conducted while the MS is in the STANDBY state.

NOTE: Circuit mode calls in the STANDBY state are only permitted if allowed by the "Class of MS" (refer to clause 16.10.5).

### 28.3.3.4.4 Type D - Restricted IP single mode

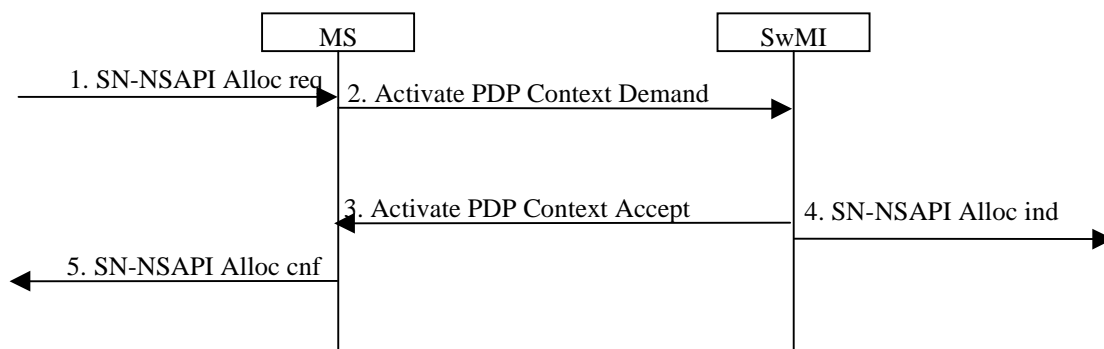

The MS is engaged to one service at a time; if MS is engaged in TETRA Packet data it does not accept circuit mode speech/data and does not support SDS and vice versa:

- 1) While the MS is in the READY state i.e. engaged in TETRA Packet Data, no circuit mode speech/data may calls be set up, accepted or conducted. SDS should not be conducted while the MS is in READY state.
- 2) While the MS has an ongoing circuit mode speech/data call or is in the call set up phase, TETRA Packet data is not allowed (accepted or initiated). This means that circuit mode speech/data may be set up, accepted or conducted while the MS is in STANDBY state. SDS may also be conducted while the MS is in the STANDBY state.

### 28.3.3.5 PDP Context Activation Procedure

Successful PDP Context Activation procedure is illustrated in figure 28.10. Each numbered step is explained in the following list.

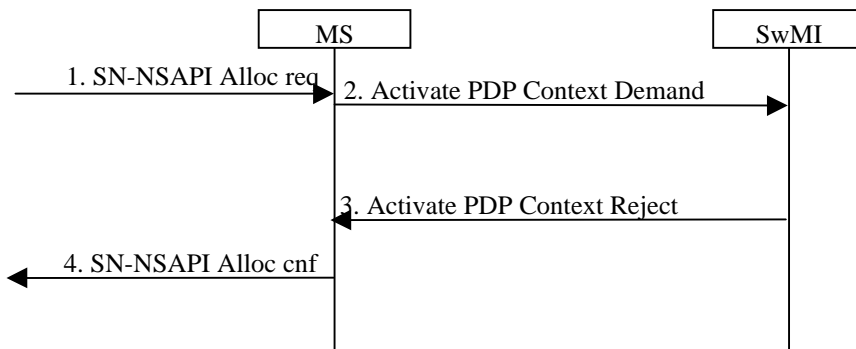

NOTE 1: In figures 28.10 to 28.13 the PDU names are presented without an "SN-" preamble.

**Figure 28.10: PDP Context activation procedure - activation accepted**

1. The SN-SAP user triggers PDP context activation by issuing a SN-NSAPI ALLOC request primitive.
2. The MS sends an SN-ACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS indicates the form of IP address it wishes to use in the information element "Address Type Identifier in Demand". If supported, the MS shall request the QoS it requires in the "QoS" information element. The requested QoS shall be derived from information in the NSAPI QoS negotiation parameter of the SN-NSAPI ALLOC request primitive. The MS shall start PDP\_ACTIVATE\_WAIT timer.
3. SwMI inserts the NSAPIs in its PDP Contexts. The SwMI returns an SN-ACTIVATE PDP CONTEXT ACCEPT PDU to the MS. The SwMI is now able to route PDP PDUs to and from MS. If the MS indicated a QoS requirement, and the SwMI decides to grant a different QoS to that requested by the MS, the SwMI indicates the QoS it expects to provide for this PDP context in the "QoS" information element (see clause 28.3.3.0). The MS shall stop PDP\_ACTIVATE\_WAIT timer.
4. The SwMI SN-SAP user is informed about PDP context activation by the SwMI SNDSCP issuing SN-NSAPI ALLOC indication primitive.
5. The MS SN-SAP user is informed about successful PDP context activation and any negotiated QoS by the MS SNDSCP issuing SN-NSAPI ALLOC confirm primitive.

Unsuccessful PDP Context Activation procedure due to SwMI rejection is illustrated in figure 28.11. Each numbered step is explained in the following list.

**Figure 28.11: PDP context activation procedure - activation rejected**

1. The SN-SAP user triggers PDP context activation by issuing SN-NSAPI ALLOC request primitive.
2. The MS sends an SN-ACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS shall start PDP\_ACTIVATE\_WAIT timer.
3. SwMI rejects activation by returning a SN-ACTIVATE PDP CONTEXT REJECT PDU to the MS. The MS shall stop PDP\_ACTIVATE\_WAIT timer.
4. The MS SN-SAP user is informed about unsuccessful PDP context activation by the MS SNDSCP issuing SN-NSAPI ALLOC confirm primitive.

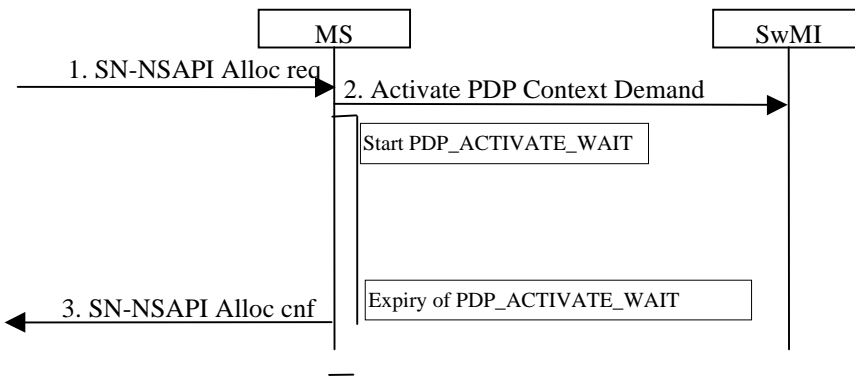

NOTE 2: For direct access, the BS always supports the SNDSCP service when the "system wide services" information element in the D-MLE-SYSINFO-DA (and the D-MLE-SYNC-DA) PDU indicates "normal mode" (system wide services supported); see clause 18. The MS SNDSCP may send the SwMI an SN-ACTIVATE PDP CONTEXT DEMAND PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or the D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported"; however the BS in this mode may temporarily not support the SNDSCP service, in which case the BS may send the SN-ACTIVATE PDP CONTEXT REJECT PDU with reject cause "SNDSCP service temporarily not available". If the MS receives an SN-ACTIVATE PDP CONTEXT REJECT PDU with reject cause "SNDSCP service temporarily not available", the MS should not continue to send the SN-ACTIVATE PDP CONTEXT DEMAND PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA or D-MLE-SYNC-DA PDUs is indicating "system wide services temporarily not supported" (though the MS is not precluded from occasionally sending the SN-ACTIVATE PDP CONTEXT DEMAND PDU).

A conventional access MS is not permitted to send the SN-ACTIVATE PDP CONTEXT DEMAND PDU while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDCCP service is not available on this cell".

NOTE 3: The MS is not permitted to send the SN-ACTIVATE PDP CONTEXT DEMAND PDU on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

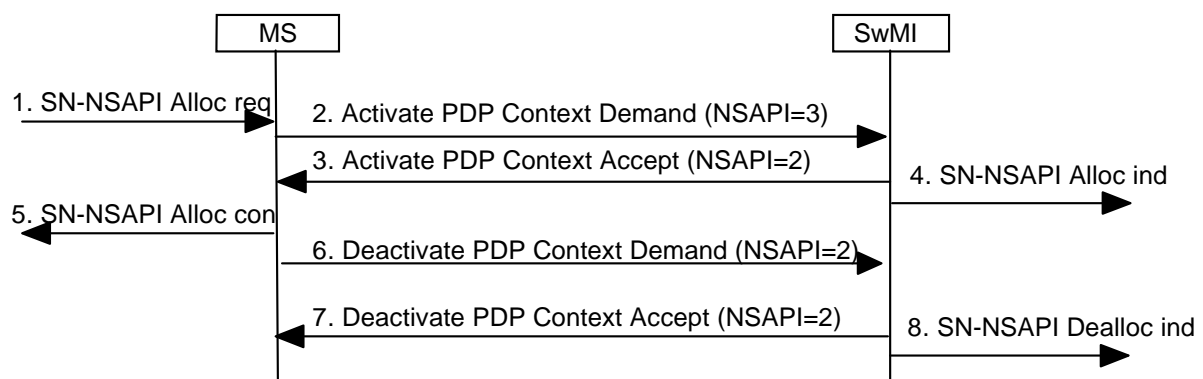

Unsuccessful PDP Context Activation procedure due to expiry of PDP\_ACTIVATE\_WAIT timer is illustrated in the figure 28.12. Each numbered step is explained in the following list.

**Figure 28.12: PDP context activation procedure - no response to activation**

1. The SN-SAP user triggers PDP context activation by issuing SN-NSAPI ALLOC request primitive.
2. The MS sends an SN-ACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS shall start PDP\_ACTIVATE\_WAIT timer.
3. Timer PDP\_ACTIVATE\_WAIT timer expires. The MS SN-SAP user is informed about unsuccessful PDP context activation by the MS SNDCCP issuing SN-NSAPI ALLOC confirm primitive.

Unsuccessful PDP Context Activation procedure due to wrong NSAPI in the SwMI's response is illustrated in the figure 28.13. Each numbered step is explained in the following list.

**Figure 28.13: PDP context activation procedure - wrong NSAPI**

1. The SN-SAP user triggers PDP context activation by issuing SN-NSAPI ALLOC request primitive.
2. The MS sends an SN-ACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS shall start PDP\_ACTIVATE\_WAIT timer.
3. SwMI inserts the NSAPIs in its PDP Contexts. The SwMI returns an SN-ACTIVATE PDP CONTEXT ACCEPT PDU to the MS. The MS shall stop the PDP\_ACTIVATE\_WAIT timer.
4. The SwMI SN-SAP user is informed about PDP context activation by the SwMI SNDSCP issuing SN-NSAPI ALLOC indication primitive.
5. The NSAPI in the Demand and Accept differ, and hence the MS SN-SAP user is informed about the failed PDP context activation by the MS SNDSCP issuing SN-NSAPI ALLOC confirm primitive.
6. The MS deactivates the NSAPI issued by the SwMI by sending a SN-DEACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS shall start the PDP\_DEACTIVATE\_WAIT timer.
7. The SwMI shall respond by sending a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU to the MS. On reception of the SN-DEACTIVATE PDP CONTEXT ACCEPT PDU, the MS shall stop the PDP\_DEACTIVATE\_WAIT timer.
8. The SwMI SN-SAP user is informed about PDP context deactivation by the SwMI SNDSCP issuing SN-NSAPI DEALLOC indication primitive.

If the PDP context activation procedure fails, then the MS SNDSCP service user may attempt another activation to the same PDP address up to a maximum number RETRY\_ACTIVATION of attempts.

### 28.3.3.5a PDP context modification procedure

It is optional for an MS and SwMI to support PDP context modification.

Normally, MSs should be responsible for initiating PDP context modification, either because the application's QoS requirements have changed, or because the MS has observed that the SwMI is no longer able to provide the previously agreed QoS.

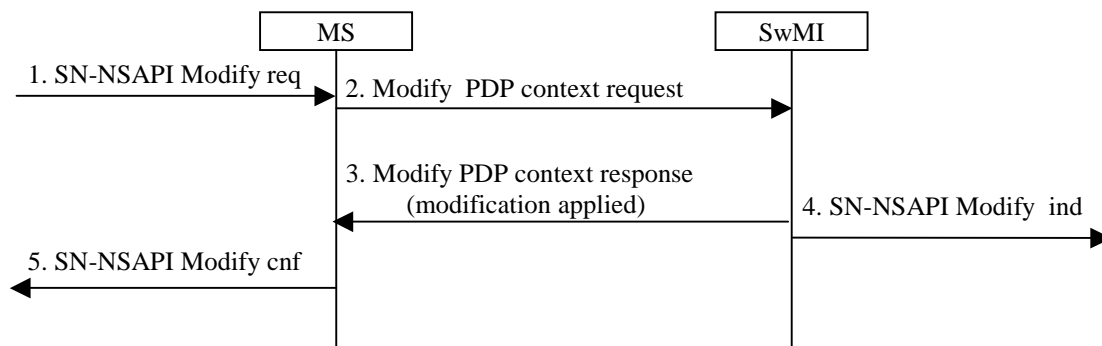

A conventional access MS shall not attempt PDP context modification while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDSCP service is not available on this cell".

The SwMI shall not use the PDP context modification procedure to increase an already agreed QoS above the highest value requested by the MS during activation and modification of the present PDP context. The SwMI is not required to modify PDP contexts every time the available QoS changes. The SwMI may initiate modification of a PDP context if it becomes unable to support a previously agreed schedule for slot grants on that PDP context. See also clause 28.3.5.6.

The MS shall not reject a SwMI-initiated PDP context modification.

Successful PDP Context modification procedure initiated by the MS is illustrated in the figure 28.14. Each numbered step is explained in the following list.

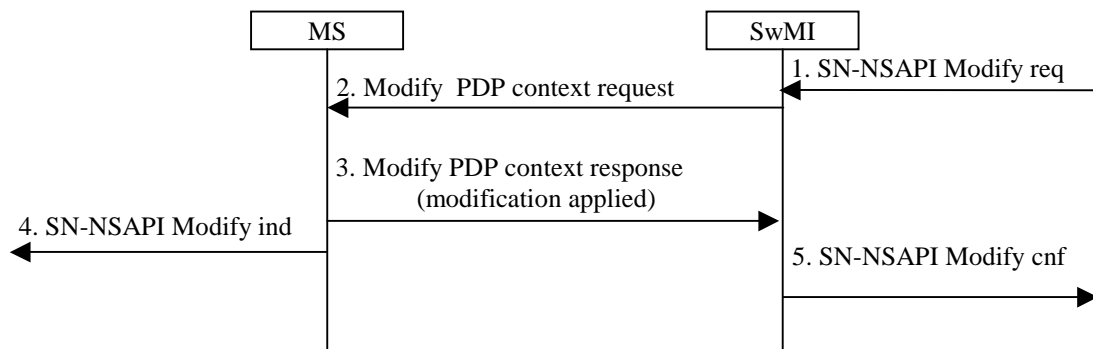

NOTE 1: In figures 28.14 to 28.18 the PDU names are presented without an "SN-" preamble.

**Figure 28.14: MS-initiated PDP Context modification procedure - modification accepted**

1. The MS's SN-SAP user triggers PDP context modification by issuing a SN-NSAPI MODIFY request primitive.
2. The MS sends an SN-MODIFY PDP CONTEXT REQUEST PDU containing a proposed QoS to the SwMI. The MS shall start PDP\_MODIFY\_WAIT timer.
3. SwMI modifies its recorded QoS information for the PDP context and returns an SN-MODIFY PDP CONTEXT RESPONSE PDU (modification result = modification applied) to the MS. If the SwMI decides to grant a modified QoS that differs from the QoS requested by the MS, the SwMI includes a QoS information element indicating the QoS offered by the SwMI (see clause 28.3.3.0). (The modified QoS offered by the SwMI should differ from the previously agreed QoS). SN-DATA and SN-UNITDATA PDUs for this PDP context should now experience the modified QoS. The MS shall stop the PDP\_MODIFY\_WAIT timer.
4. The SwMI SN-SAP user is informed about the PDP context modification by the SwMI SNDSCP issuing a SN-NSAPI MODIFY indication primitive.
5. The MS SN-SAP user is informed about the PDP context modification by the MS SNDSCP issuing a SN-NSAPI MODIFY confirm primitive.

The SwMI may initiate PDP context modification when it needs to reduce the level of the presently agreed QoS and when it wishes to advise the MS that it is now increasing the level of QoS to more closely match the MS's request. Successful PDP Context modification procedure initiated by the SwMI is illustrated in the figure 28.15. Each numbered step is explained in the following list.

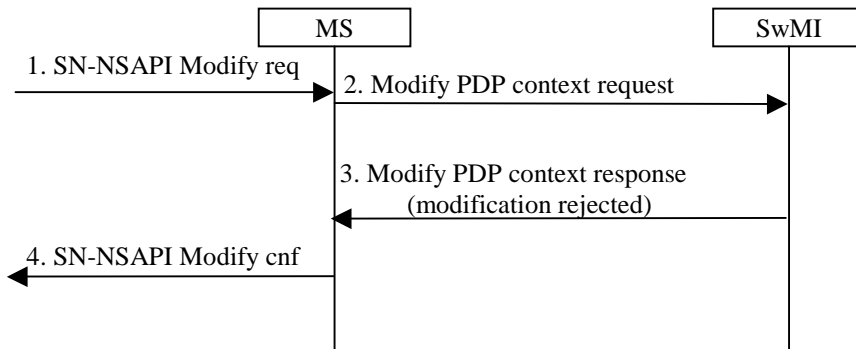

**Figure 28.15: SwMI-initiated PDP Context modification procedure - modification accepted**

1. The SwMI SN-SAP user triggers PDP context modification by issuing a SN-NSAPI MODIFY request primitive.
2. The SwMI sends an SN-MODIFY PDP CONTEXT REQUEST PDU containing a modified QoS to the MS.
3. The MS modifies its recorded QoS information for the PDP context and returns an SN-MODIFY PDP CONTEXT RESPONSE PDU (modification result = modification applied) to the SwMI. PDP PDUs for this PDP context should now experience the modified QoS.
4. The MS SN-SAP user is informed about PDP context modification by the SwMI SNDSCP issuing SN-NSAPI MODIFY indication primitive.
5. The SwMI SN-SAP user is informed about the PDP context modification by the MS SNDSCP issuing SN-NSAPI MODIFY confirm primitive.

NOTE 2: The SwMI may also initiate PDP context modification as a result of SwMI layer 2 changes, without first receiving a SN-NSAPI MODIFY request primitive. In this case, the SwMI informs the SwMI SN-SAP user of the change in QoS by issuing a SN-NSAPI MODIFY indication primitive (and not a SN-NSAPI MODIFY confirm primitive).

The MS shall not reject a PDP context modification initiated by the SwMI (but it may subsequently deactivate the modified PDP context or may attempt to modify it).

Unsuccessful PDP context modification procedure due to SwMI rejection is illustrated in the figure 28.16. Each numbered step is explained in the following list.

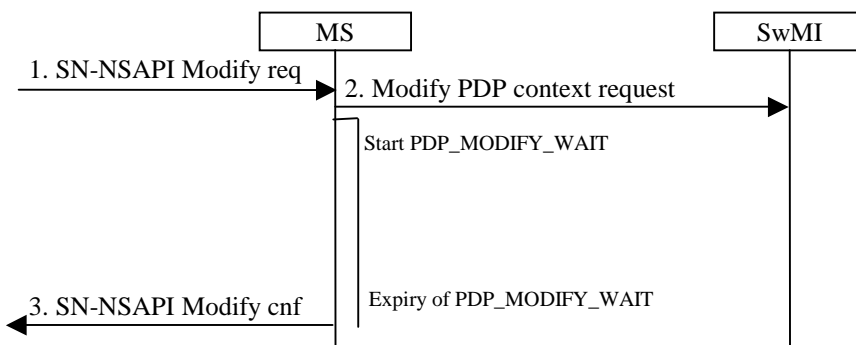

**Figure 28.16: MS-initiated PDP context modification procedure - modification rejected by SwMI**

1. The SN-SAP user triggers PDP context modification by issuing a SN-NSAPI MODIFY request primitive.
2. The MS sends an SN-MODIFY PDP CONTEXT REQUEST PDU containing a proposed QoS to the SwMI. The MS shall start PDP\_MODIFY\_WAIT timer.
3. SwMI rejects modification by returning a SN-MODIFY PDP CONTEXT RESPONSE PDU (modification result = modification rejected) to the MS. The QoS previously agreed for the PDP context remains unchanged. The MS shall stop PDP\_MODIFY\_WAIT timer.
4. The MS SN-SAP user is informed about unsuccessful PDP context modification by the MS SNDSCP issuing a SN-NSAPI MODIFY confirm primitive.

NOTE 3: For direct access, the BS always supports the SNDSCP service when the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "normal mode" (system wide services supported); see clause 18. The MS SNDSCP may send the SwMI an SN-MODIFY PDP CONTEXT REQUEST PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported"; however the BS in this mode may temporarily not support the SNDSCP service, in which case the BS may send the SN-MODIFY PDP CONTEXT RESPONSE PDU with reject cause "SNDSCP service temporarily not available". If the MS receives an SN-MODIFY PDP CONTEXT RESPONSE PDU with reject cause "SNDSCP service temporarily not available", the MS should not continue to send the SN-MODIFY PDP CONTEXT REQUEST PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported" (though the MS is not precluded from occasionally sending the SN-MODIFY PDP CONTEXT REQUEST PDU).

A conventional access MS is not permitted to send the SN-MODIFY PDP CONTEXT REQUEST PDU while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDSCP service is not available on this cell".

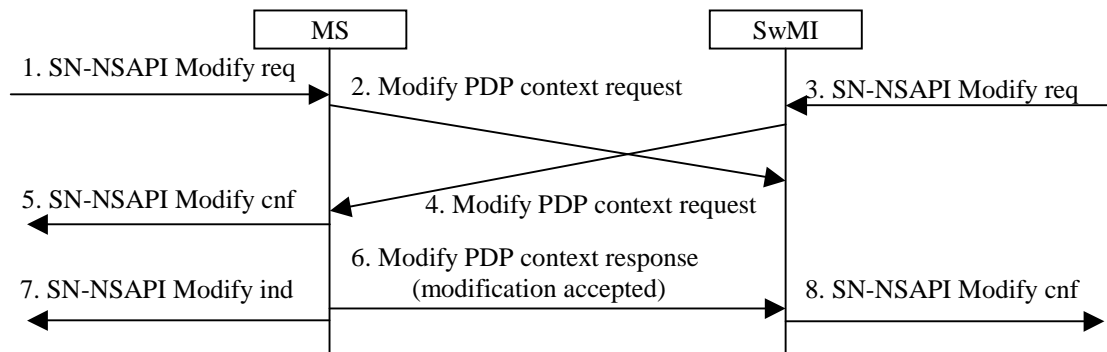

Unsuccessful PDP Context Modification procedure due to expiry of PDP\_MODIFY\_WAIT timer is illustrated in the figure 28.17. Each numbered step is explained in the following list.

**Figure 28.17: MS-initiated PDP context modification procedure - no response to modification request**

1. The SN-SAP user triggers PDP context modification by issuing a SN-NSAPI ALLOC request primitive.
2. The MS sends an SN-MODIFY PDP CONTEXT REQUEST PDU to the SwMI. The MS shall start PDP\_MODIFY\_WAIT timer.
3. Timer PDP\_MODIFY\_WAIT timer expires. The MS SN-SAP user is informed about unsuccessful PDP context modification by the MS SNDSCP issuing a SN-NSAPI MODIFY confirm primitive.

Unsuccessful MS-initiated PDP context modification procedure due to MS receiving a SN-MODIFY PDP CONTEXT REQUEST PDU from the SwMI while the PDP\_MODIFY\_WAIT timer is active is illustrated in the figure 28.18. Each numbered step is explained in the following list.

**Figure 28.18: MS-initiated PDP context modification procedure - SwMI also initiating modification of the same PDP context**

1. The SN-SAP user triggers PDP context modification by issuing a SN-NSAPI MODIFY request primitive.
2. The MS sends an SN-MODIFY PDP CONTEXT REQUEST PDU. The MS shall start PDP\_MODIFY\_WAIT timer.
3. The SwMI SN-SAP user triggers PDP context activation by issuing SN-NSAPI MODIFY request primitive.
4. The SwMI SNDSCP sends an SN-MODIFY PDP CONTEXT REQUEST PDU containing a proposed QoS to the MS before it receives the SN-MODIFY PDP CONTEXT RESPONSE PDU from the MS. The SwMI shall now discard any SN-MODIFY PDP CONTEXT REQUEST PDU received from the MS until after it receives SN-MODIFY PDP CONTEXT RESPONSE PDU (modification result = modification applied) from the MS.
5. On receipt of SN-MODIFY PDP CONTEXT REQUEST PDU while the PDP\_MODIFY\_WAIT timer is active, the MS SNDSCP informs the MS SN-SAP user about unsuccessful PDP context modification by issuing SN-NSAPI MODIFY confirm primitive. The MS shall stop PDP\_MODIFY\_WAIT timer.
6. The MS SNDSCP sends receives SN-MODIFY PDP CONTEXT RESPONSE PDU (modification result = modification applied) to the SwMI.
7. The MS SN-SAP user is informed about PDP context modification by the MS SNDSCP issuing SN-NSAPI MODIFY indication primitive.
8. The SwMI SN-SAP user is informed about the PDP context modification by the SwMI SNDSCP issuing SN-NSAPI MODIFY confirm primitive.

In general, if MS-initiated PDP context modification procedure fails, then the MS SNDSCP service user may attempt an identical modification of that PDP context up to a maximum number RETRY\_MODIFICATION of attempts before deactivation of the PDP context.

### 28.3.3.6 PDP context deactivation procedure

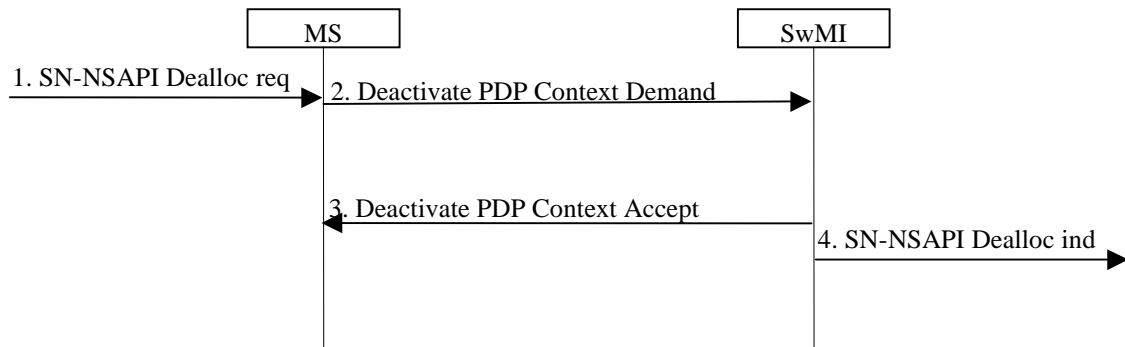

#### 28.3.3.6.0 General

Either a MS or the SwMI may initiate the deactivation procedure.

#### 28.3.3.6.1 MS originated PDP context deactivation procedure

MS originated PDP Context Deactivation procedure is illustrated in figure 28.19. Each numbered step is explained in the following list.

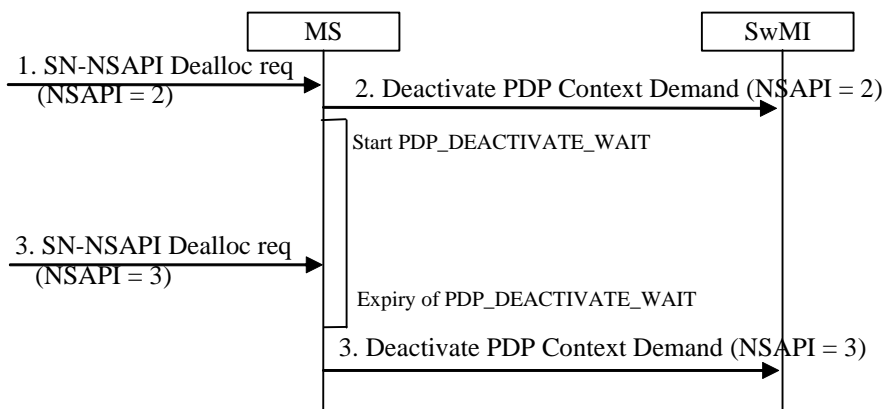

NOTE: In figures 28.19 to 28.21 the PDU names are presented without an "SN-" preamble.

**Figure 28.19: PDP context deactivation procedure**

1. The SN-SAP user triggers PDP context deactivation by issuing SN-NSAPI DEALLOC request primitive.
2. The MS sends a SN-DEACTIVATE PDP CONTEXT DEMAND PDU to the SwMI. The MS shall start PDP\_DEACTIVATE\_WAIT timer.
3. The SwMI returns a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU to the MS. The MS shall stop PDP\_DEACTIVATE\_WAIT timer.
4. The SwMI SN-SAP user is informed about PDP context deactivation by the SwMI SNDSCP issuing SN-NSAPI DEALLOC indication primitive.
5. The MS SN-SAP user is informed about PDP context deactivation by the MS SNDSCP issuing an SN-NSAPI DEALLOC confirm primitive.

MS originated PDP Context Deactivation unsuccessful procedure due to expiry of PDP\_DEACTIVATE\_WAIT timer is illustrated in figure 28.20. Each numbered step is explained in the following list.

**Figure 28.20: PDP context deactivation procedure - no response to deactivation**

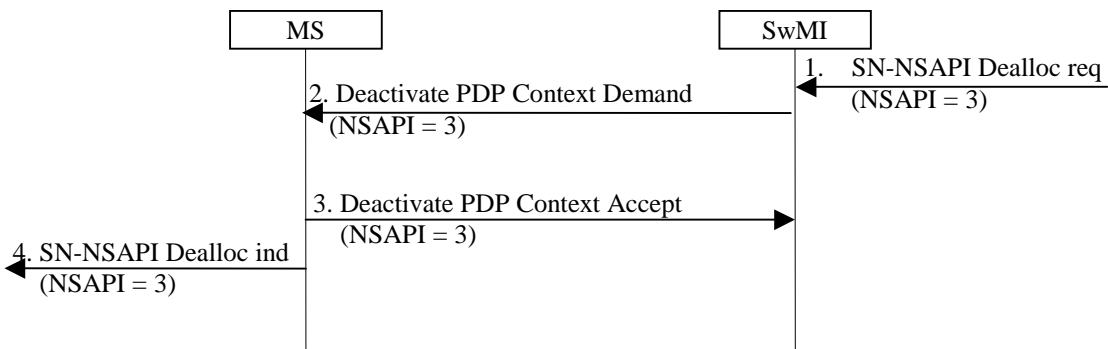

1. The SN-SAP user triggers PDP context deactivation by issuing SN-NSAPI DEALLOC request primitive (NSAPI = 2 in this scenario).

2. The MS sends a SN-DEACTIVATE PDP CONTEXT DEMAND PDU (NSAPI = 2 in this scenario) message to the SwMI. The MS shall start PDP\_DEACTIVATE\_WAIT timer.
3. The SN-SAP user triggers PDP context deactivation by issuing SN-NSAPI DEALLOC request primitive (NSAPI = 3 in this scenario).
4. Timer PDP\_DEACTIVATE\_WAIT timer expires. The MS shall not retry de-activation procedure for that NSAPI= 2. The PDP context is deactivated locally.
5. The MS sends a Deactivate PDP Context Demand (NSAPI = 3 in this scenario) message to the SwMI. The MS shall start PDP\_DEACTIVATE\_WAIT timer.

The MS may use Deactivation type parameter value "Deactivation of all NSAPIs" when sending the SN-DEACTIVATE PDP CONTEXT DEMAND PDU. Should this happen the MS shall deactivate all its active PDP Contexts locally. The SwMI shall respond to the Demand by sending a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU having Deactivation type parameter value "Deactivation of all NSAPIs" and deactivate all NSAPIs for that MS.

### 28.3.3.6.2 SwMI originated context deactivation procedure

SwMI originated PDP Context Deactivation procedure is illustrated in the figure 28.21. Each numbered step is explained in the following list.

**Figure 28.21: SwMI originated PDP context deactivation procedure**

1. The SN-SAP user triggers PDP context deactivation by issuing SN-NSAPI DEALLOC request primitive (NSAPI = 3 in this scenario).
2. The SwMI sends a SN-DEACTIVATE PDP CONTEXT DEMAND PDU to the MS.
3. The MS sends a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU to the SwMI.
4. The MS SN-SAP user is informed about PDP context deactivation by the MS Sndcp issuing SN-NSAPI DEALLOC indication primitive

In a case of failed PDP Context deactivation the SwMI may retry deactivation.

The SwMI may use Deactivation type parameter value "Deactivation of all NSAPIs" when sending the SN-DEACTIVATE PDP CONTEXT DEMAND PDU. Should this happen, the MS shall respond to the demand by sending a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU having Deactivation type parameter value "Deactivation of all NSAPIs" and deactivate all NSAPIs locally.

### 28.3.3a Assignment of layer 2 logical links to PDP contexts

Four different types of layer 2 logical links are available for transmission of N-PDUs. These are:

- original acknowledged advanced link;
- extended acknowledged advanced link;
- unacknowledged advanced link; and

- unacknowledged basic link.

The MS may support up to four acknowledged advanced links. One of these may be an original advanced link or an extended advanced link. The other three shall be extended advanced links. Extended advanced links may use a larger transmission window size than the original advanced link, and this may be beneficial where multiple applications are using the same link. However, extended advanced links have slightly less capacity than the original advanced link.

Information about the support by a conventional access cell for the original advanced link is broadcast in the "BS service details" information element of the D-MLE-SYSINFO and D-MLE-SYSINFO-Q PDUs. Information about the support by a conventional access cell for extended advanced links is broadcast in section 1 of the "extended services broadcast" information element of the MAC SYSINFO PDU and the MAC SYSINFO-Q PDU. Broadcast parameters are passed to the MS SNDCP in the MLE-INFO primitive.

A direct access cell always supports original and extended advanced links when the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "normal mode" (system wide services supported). When the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "system wide services temporarily not supported", it is optional for the direct access cell to support original and extended advanced links.

**NOTE:** If an MS on a direct access cell receives an AL-DISC PDU with a report "service temporarily unavailable" the MS should not continue to attempt to establish advanced links while the "system wide services" information element indicates "system wide services temporarily not supported" (though the MS is not precluded from occasionally attempting to establish advanced links).

The MS may also support up to four unacknowledged advanced links per address and a single unacknowledged basic link.

The MS SNDCP shall assign a layer 2 link to a PDP context before transmitting or receiving SN-DATA or SN-UNITDATA PDUs for that PDP context.

The MS SNDCP shall request the MS LLC to set up acknowledged advanced links when required, and the SwMI shall set up unacknowledged advanced links when required (see clause 28.3.4.2). The unacknowledged basic link does not require setting up.

If the MS and SwMI negotiated QoS during activation of the PDP context, the MS's choice of layer 2 logical link type shall be based on the data class information element included in the QoS information element of the most recently exchanged SN-ACTIVATE PDP CONTEXT ACCEPT PDU or SN-MODIFY PDP CONTEXT RESPONSE PDU for that PDP context. If the MS and SwMI did not negotiate QoS during PDP context activation, the MS SNDCP shall assign an acknowledged advanced link to the PDP context. Table 28.15 specifies how the MS's choice of logical link type depends on negotiated data class and use of QoS negotiation.

**Table 28.15: Assignment of layer 2 logical link type to PDP context**

| Data class   | Link type                            |
|--|--------------------------------------|
| Background   | Acknowledged advanced link           |
| Telemetry  | Acknowledged advanced link           |
| Real-time  | Unacknowledged basic link (see note) |
| QoS not negotiated   | Acknowledged advanced link           |
| <b>NOTE:</b> It is expected that a real-time class PDP context might be used only for unacknowledged streamed data. If any associated control signalling needs to be sent using an acknowledged service then a telemetry or background class PDP context using an acknowledged advanced link with small window size may be appropriate for the control signalling. |                                      |

The MS SNDCP shall assign one of the available advanced links to a PDP context before the MS or SwMI commences transmitting SN-DATA PDUs for that PDP context. The MS SNDCP may use the contents of the QoS parameter in the most recently exchanged SN-ACTIVATE PDP CONTEXT ACCEPT PDU or SN-MODIFY PDP CONTEXT RESPONSE PDU (containing modify type = "response") for that PDP context, if available, to assist in its choice of acknowledged advanced link identifier and type (original or extended). If the MS and SwMI did not negotiate QoS during PDP context activation, the MS should choose an acknowledged advanced link suitable for background class data (see clause 28.3.3b).

When assigning particular acknowledged advanced links to PDP contexts, the MS may choose to group PDP contexts requiring the same data class and reliability class on the same acknowledged advanced link. When an advanced link is required, the MS SNDCP may request LLC to set up the acknowledged advanced link with a TL-SDU window size, maximum number of TL-SDU transmissions and maximum number of segment retransmissions suited to the QoS requirements of the PDP contexts assigned to that link (see clause 28.3.3b).

When the SwMI transmits an SN-DATA PDU, it should use the most suitable existing acknowledged advanced link.

If the MS receives an individually addressed SN-DATA TRANSMIT REQUEST for a PDP context whose assigned acknowledged advanced link has not been set up, the MS should set up the assigned acknowledged advanced link as soon as the MS reaches the PDCH. If the SwMI has already started using a different acknowledged advanced link, the SwMI should change to the new, more suitable link when it has delivered all the SN-DATA PDUs already being sent on the previous acknowledged advanced link for that PDP context, if it thinks the new advanced link is more suitable.

When the SwMI wishes to transmit unacknowledged packet data to one or more MSs, it may use the unacknowledged basic link (e.g. for real-time class data) or it shall set up and use an unacknowledged advanced link.

### 28.3.3b Choice of layer 2 logical link parameters

When setting up an acknowledged advanced link, the MS should attempt to set the parameters to suit the QoS requirements of the PDP contexts assigned to use that link.

An advanced link assigned for telemetry class data may be given a window size greater than 1 to help the transmitter to catch up with the schedule after a scheduled grant is missed or a transmission fails, but kept small (e.g.  $N.272 = 2$  or  $3$ ) to limit the loss of partially delivered TL-SDUs if the link has to be reset. The maximum number of TL-SDU retransmissions ( $N.273$ ) and the maximum number of segment retransmissions ( $N.274$ ) may be set to a small number (e.g.  $2$  or  $3$ ), so that the transmitter can abandon an undelivered TL-SDU, reset the advanced link and move on to the new TL-SDU before too much delay is incurred.

An advanced link assigned for use by background class data may be given a large window size (e.g.  $N.272 = 15$ ), a large maximum number of TL-SDU retransmissions (e.g.  $N.273 = 7$ ) and a large maximum number of segment retransmissions (e.g.  $N.274 = 15$ ) to maximize the chance of ultimately delivering the TL-SDU. However, if a low delay is required, it may be preferable to use a small window size.

SNDCP should set the FCS flag in the MLE-UNITDATA request primitive to instruct the LLC to use the FCS when transmitting an SN-DATA PDU containing best effort class data or telemetry class data requiring high reliability. SNDCP should set the FCS flag to instruct the LLC not to use an FCS when transmitting an SN-UNITDATA PDU containing real-time class data.

## 28.3.4 Packet Data Channel (PDCH) handling procedures

### 28.3.4.0 General

The control channel procedures specified in the present document apply for TETRA packet data. The control channel used for TETRA packet data SN-PDU transfer is called the Packet Data Channel (PDCH). The SwMI may add channel allocation to SN-DATA TRANSMIT REQUEST PDU (Data from SwMI to MS). The SwMI may add channel allocation to SN-DATA TRANSMIT RESPONSE PDU (data from MS to SwMI) if the MS's request to transmit is accepted by the SwMI.

Clause 28.3.4.8 describes how the SwMI should select an appropriate PDCH.

The channel is released by the SwMI by issuing SN-END OF DATA PDU when SwMI's READY timer expires. Where the MS was directed to the PDCH using a channel allocation, then the SN-END OF DATA PDU shall include channel allocation to common control channel. If the READY timer expires in the MS, then the MS shall issue SN-END OF DATA PDU and await a corresponding SN-END OF DATA PDU from the SwMI.

If the packet data service in the MS is overridden by some other service requiring an immediate channel change, the MS may release the channel without waiting to receive an SN-END OF DATA PDU by sending the SwMI an SN-END OF DATA PDU indicating "immediate service change" and then immediately entering the STANDBY state.

If the MS receives an SN-NSAPI-DEALLOC request primitive from the SNDCP service user requesting deactivation of a PDP context with an active CONTEXT\_READY timer at a time when no other PDP contexts have active CONTEXT\_READY timers, or if the SN-NSAPI-DEALLOC request primitive requested deactivation of all PDP contexts, the MS may attempt to return to the STANDBY state prior to the expiry of the READY timer by sending an SN-END OF DATA PDU that does not indicate "immediate service change". The MS shall then await a corresponding SN-END OF DATA PDU from the SwMI before entering the STANDBY state. (However, if the packet data service in the MS is at the same time overridden by some other service requiring an immediate channel change, the MS may indicate "immediate service change" in the SN-END OF DATA PDU as described above.) If the SN-NSAPI-DEALLOC request primitive did not request deactivation of all PDP contexts with active CONTEXT-READY timers, the MS should not send an SN-END OF DATA PDU in response to the primitive (except in the case where an immediate service change is required). When the MS returns to the STANDBY state it shall deactivate the indicated PDP contexts as described in clause 28.3.3.

An SN-END OF DATA PDU indicating "immediate service change" may be sent on the PDCH, some other allocated channel or a common control channel.

NOTE 1: The case where the READY timer expires in the MS prior to reception of a SN-END OF DATA PDU should be viewed as an exceptional case. To ensure the MS receives a SN-END OF DATA PDU from the SwMI before its READY timer expires, the SwMI should set its own READY timer to a shorter value than the one sent to the MS in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU.

NOTE 2: The packet channel is defined from a single MS point of view (except when the SwMI uses multicast address). Thus here releasing the PDCH means releasing the channel for a single MS. In the same control channel there may be also more than one MS at the same time.

NOTE 3: The MS may choose to adjust its value of T.208 against READY timer on a PDCH to ensure that the use of SN-END OF DATA will be the normal way of leaving a PDCH.

#### 28.3.4.1 Logical link handling

Table 28.16 defines the division between basic link and advanced link based on SN-PDU type.

**Table 28.16: Logical link usage by SN-PDUs**

| SN-PDU                             | Basic link  | Advanced links |
|------------------------------------|---|----------------|
| SN-ACTIVATE PDP CONTEXT DEMAND     | x   |                |
| SN-DEACTIVATE PDP CONTEXT DEMAND   | x   |                |
| SN-ACTIVATE PDP CONTEXT ACCEPT     | x   |                |
| SN-ACTIVATE PDP CONTEXT REJECT     | x   |                |
| SN-DEACTIVATE PDP CONTEXT ACCEPT   | x   |                |
| SN-DATA-PRIORITY ACKNOWLEDGEMENT   | x   |                |
| SN-DATA-PRIORITY INFORMATION       | x   |                |
| SN-DATA-PRIORITY REQUEST           | x   |                |
| SN-MODIFY PDP CONTEXT REQUEST      | x   |                |
| SN-MODIFY PDP CONTEXT RESPONSE     | x   |                |
| SN-MODIFY PDP CONTEXT AVAILABILITY | x   |                |
| SN-MODIFY PDP CONTEXT USAGE        | x   |                |
| SN-UNITDATA                        | x (see note)  | x (see note)   |
| SN-DATA                            |   | x              |
| SN-DATA TRANSMIT REQUEST           | x   |                |
| SN-DATA TRANSMIT RESPONSE          | x   |                |
| SN-NOT SUPPORTED                   | x   |                |
| SN-RECONNECT                       | x   |                |
| SN-PAGE REQUEST                    | x   |                |
| SN-PAGE RESPONSE                   | x   |                |
| SN-END OF DATA                     | x   |                |
| NOTE:                              | The SwMI and MS use the unacknowledged basic link service for real-time class data. The SwMI uses the unacknowledged advanced link service for point-to-multipoint telemetry class and background class data. |                |

The basic link's unacknowledged and acknowledged services are used by the MS and SwMI according to table 28.17.

**Table 28.17: Usage of basic link unacknowledged and acknowledged services**

| SN-PDU   | Unacknowledged | Acknowledged   |
|--|----------------|----------------|
| SN-ACTIVATE PDP CONTEXT DEMAND   |                | x              |
| SN-DEACTIVATE PDP CONTEXT DEMAND   |                | x              |
| SN-ACTIVATE PDP CONTEXT ACCEPT   |                | x              |
| SN-ACTIVATE PDP CONTEXT REJECT   |                | x              |
| SN-DEACTIVATE PDP CONTEXT ACCEPT   |                | x              |
| SN-DATA-PRIORITY ACKNOWLEDGEMENT   |                | x              |
| SN-DATA-PRIORITY INFORMATION   |                | x              |
| SN-DATA-PRIORITY REQUEST   |                | x              |
| SN-MODIFY PDP CONTEXT REQUEST  |                | x              |
| SN-MODIFY PDP CONTEXT RESPONSE   |                | x              |
| SN-MODIFY PDP CONTEXT AVAILABILITY   |                | x              |
| SN-MODIFY PDP CONTEXT USAGE  |                | x              |
| SN-DATA TRANSMIT REQUEST   | x (see note 1) | x (see note 1) |
| SN-DATA TRANSMIT RESPONSE  | x              | x (see note 2) |
| SN-NOT SUPPORTED   | x (see note 1) | x (see note 1) |
| SN-RECONNECT   |                | x              |
| SN-PAGE REQUEST  | x (see note 2) | x (see note 2) |
| SN-PAGE RESPONSE   |                | x              |
| SN-END OF DATA   | x (see note 1) | x (see note 1) |
| SN-UNITDATA  | x (see note 3) |                |
| NOTE 1: The SwMI may use either unacknowledged or acknowledged basic link service and the MS shall use acknowledged service. |                |                |
| NOTE 2: The SwMI may use either acknowledged or unacknowledged basic link service.   |                |                |
| NOTE 3: The SwMI and MS use the unacknowledged basic link service for real-time class data.                                  |                |                |

The lower layer service selection is informed in the protocol model to the lower layers in the corresponding MLE service request primitive as the "layer 2 service" parameter.

### 28.3.4.2 Logical link setup

See also clause 28.3.4.8 on selection of physical channels and clause 28.3.5.2a on usage of the "resource request" information element.

N-PDUs may be sent on acknowledged advanced links, unacknowledged advanced links, and on the unacknowledged basic link. Clause 28.3.3a describes how SMDCP assigns particular logical links to PDP contexts. Clause 28.3.3b suggests how the MS SMDCP may choose appropriate link parameters.

The MS shall take the active part in establishing acknowledged advanced links. Up to four advanced links may be used by the SMDCP per MS for acknowledged service. The MS shall not establish an advanced link for packet data if there are no PDP contexts active. Furthermore the SMDCP entity tracks whether each underlying advanced link is established or not.

The SwMI shall take the active part in establishing unacknowledged advanced links. Up to four advanced links may be used by the SMDCP per address for the unacknowledged service, and shall be established when required by the SwMI.

The unacknowledged basic link does not need to be set up.

The advanced links are established on the PDCH under the control of SMDCP. Once established, the advanced links stay established even when the MS resides on the common control channel (MCCH or MCCH-Q or common SCCH) but still the MS SMDCP shall not use an advanced link without requesting the SwMI for permission.

NOTE 1: The MS may be involved in circuit mode speech/data in between accessing a PDCH. Then the advanced links remain established.

The MS shall not attempt to establish an acknowledged advanced link on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

There are four scenarios listed below where a MS may establish or reset the acknowledged advanced link.

a) Inbound or outbound data pending - no active advanced link

A MS shall establish an acknowledged advanced link if the MS has assigned an acknowledged advanced link to the relevant PDP context and the assigned acknowledged advanced link is not already active either if the MS has data to send or if the MS is notified by an individually-addressed SN-DATA TRANSMIT REQUEST PDU from the SwMI that there is outbound data pending. This scenario is the typical scenario where a MS, after successfully activating a PDP context, wishes to send data. An example of the establishment of an advanced link in this scenario is presented in figures 28.22 to 28.25.

NOTE 2: The examples described below assume a channel allocation is required to direct a MS from its current channel to the PDCH. There may however be occasions where the SwMI decides to allow packet data transfer on a common control channel and therefore a channel allocation may not be required.

NOTE 3: The examples described below shows the MLE as the entity in the SwMI negotiating the establishment of advanced links. This is due to there being no information contained within the AL-SETUP PDUs to indicate the layer 3 entity in the MS (e.g. SNDCP, SDS, SS etc) which initiated the advanced link establishment, thus the SwMI MLE entity would be expected to negotiate on behalf of all SwMI layer 3 entities. The present document does not define how the establishment of advanced links is negotiated within the SwMI.

In figure 28.22 the establishment of an acknowledged advanced link is initiated by the arrival at the MS SNDCP entity of a SN-DATA request primitive. While on a common control channel (MCCH or MCCH-Q or common SCCH), the MS will send a SN-DATA TRANSMIT REQUEST PDU on the uplink using the acknowledged basic link service. The SwMI will respond by sending a SN-DATA TRANSMIT RESPONSE PDU to the MS. The MAC-RESOURCE PDU which contains this PDU includes a "Channel Allocation" information element. As no advanced link exists, the SwMI shall direct the MS to a suitable PDCH (unless the current channel is suitable). Clause 28.3.4.8 describes the procedure which the SwMI should use to choose a suitable PDCH.

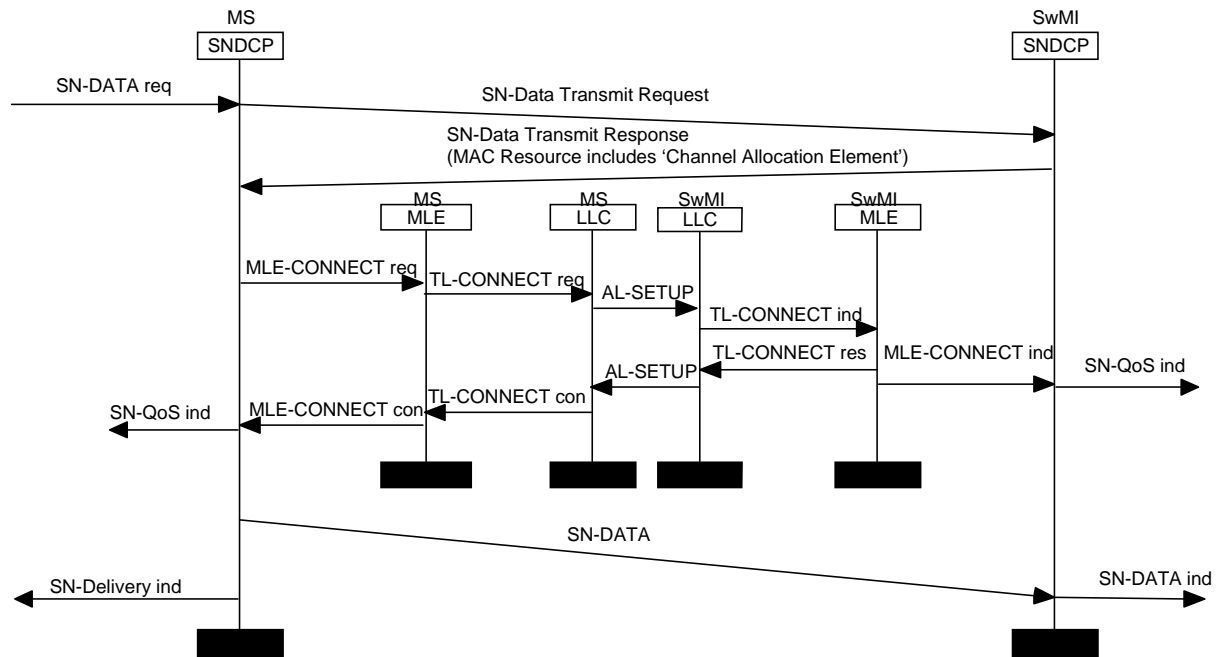

Once on the PDCH, the MS shall establish an advanced link if the advanced link assigned to the PDP context referenced in the SN-DATA request or SN-UNITDATA request primitive is not already established. This is achieved through the sending of a MLE-CONNECT request primitive to the MLE.

NOTE 4: If SNDCP did not send a "resource request" information element (see clause 28.3.5.2a), SNDCP should provide no information about throughput in the MLE-CONNECT request primitive's "quality of service (QoS) for layer 2" parameter.

Within the MAC-ACCESS PDU used to carry the AL-SETUP PDU on the uplink, the MS may include a "Reservation Requirement" for the total number of slots needed to transfer the N-PDU. The MAC-RESOURCE PDU used to carry the AL-SETUP PDU response on the downlink may include a "Slot Granting" information element to reserve the required number of slots for the MS on the uplink.

Also, the SwMI may alter the capacity of the PDCH by including in the MAC-RESOURCE PDU used to carry the AL-SETUP PDU response on the downlink a "Channel Allocation" information element with "allocation type" = 00 - see clause 23.5.4.2.1 and its clauses of the present document. (For example, the SwMI could decide to alter the number of timeslots per TDMA frame of a phase modulation PDCH depending on the number of  $\pi/4$ -DQPSK timeslots per TDMA frame requested by the MS in an AL-SETUP PDU. Or the SwMI could move the MS from a QAM PDCH to a phase modulation PDCH within the MS's declared capabilities if the MS requests a phase modulation connection in an AL-SETUP PDU sent on the QAM PDCH). Once the advanced link has been successfully established, the SNDCP service users in the MS and SwMI shall be notified using the SN-QoS indication primitive. With the advanced link successfully established, the MS may then begin sending the SN-DATA PDU.

Refer clause 28.3.4.6 on the channel change protocol.

**Figure 28.22: Successful advanced link set up, initiated by pending inbound data transfer**

In figure 28.23 the establishment of an acknowledged advanced link is initiated by the arrival at the SwMI Sndcp entity of a SN-DATA (or SN-UNITDATA) request primitive. The SwMI shall send a SN-DATA TRANSMIT REQUEST PDU on the downlink using the unacknowledged basic link service. The basic link message shall be transported using a MAC-RESOURCE PDU which, in this example, contains a "Channel Allocation" information element sending the MS to a suitable PDCH. (The procedure for choosing a PDCH is given in clause 28.3.4.)

Once on the PDCH, if the SN-DATA TRANSMIT REQUEST PDU is individually addressed, the MS shall establish an acknowledged advanced link. This is achieved through the sending of a MLE-CONNECT request primitive to the MLE. The SwMI may alter the capacity of the PDCH by including in the MAC-RESOURCE PDU used to carry the AL-SETUP PDU response on the downlink a "Channel Allocation" information element with "allocation type"= 00 - see clause 23.5.4.2.1 of the present document. (For example, the SwMI could decide to alter the number of timeslots per TDMA frame of a phase modulation PDCH depending on the number of  $\pi/4$ -DQPSK timeslots per TDMA frame requested by the MS in an AL-SETUP PDU. Or the SwMI could decide to move the MS from a QAM PDCH to a phase modulation PDCH within the MS's declared capabilities if the MS requests a phase modulation connection in an AL-SETUP PDU sent on the QAM PDCH.) Once an advanced link has been successfully established, the Sndcp service users in the MS and SwMI shall be notified using the SN-QoS indication primitive. With an advanced link successfully established, the SwMI may then begin sending the SN-DATA PDU.

Refer to clause 28.3.4.6 on the channel change protocol.

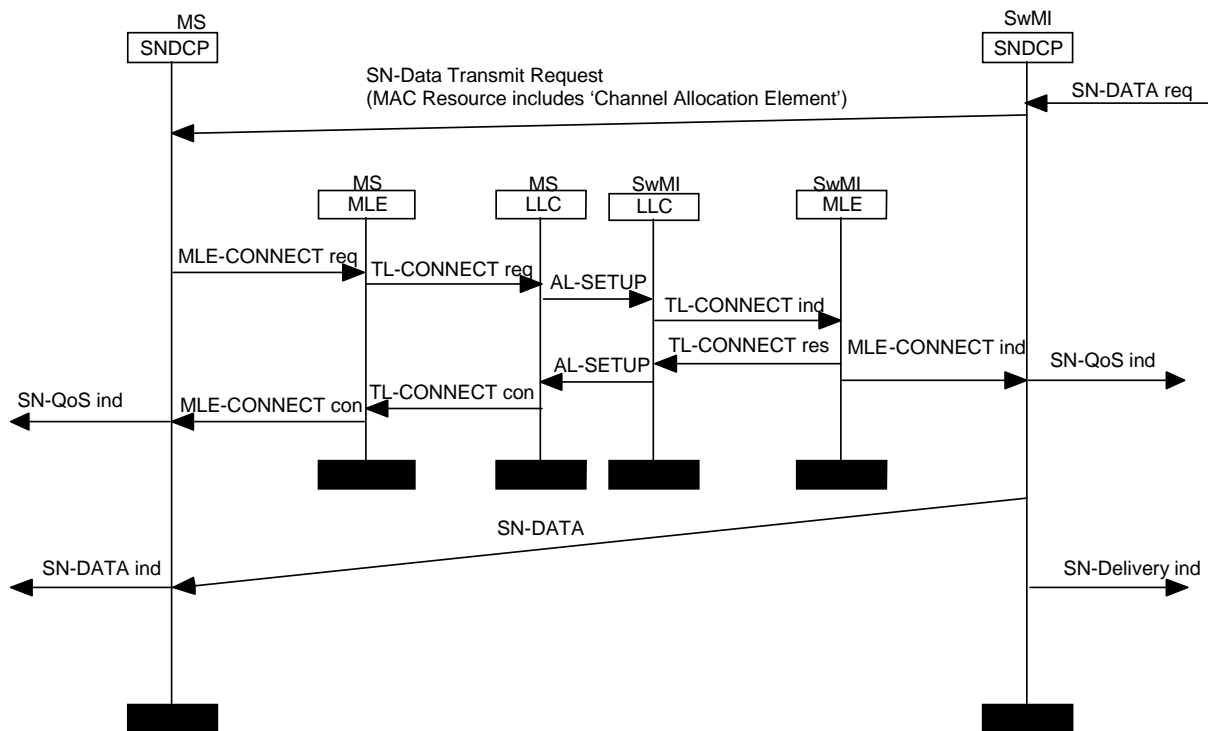

Figure 28.23: Successful advanced link set up, initiated by pending outbound data transfer

Figure 28.24 shows the case where the establishment of the advanced link fails due to the advanced link QoS being offered by the SwMI, being lower than the minimum advanced link QoS which the MS is willing to accept.

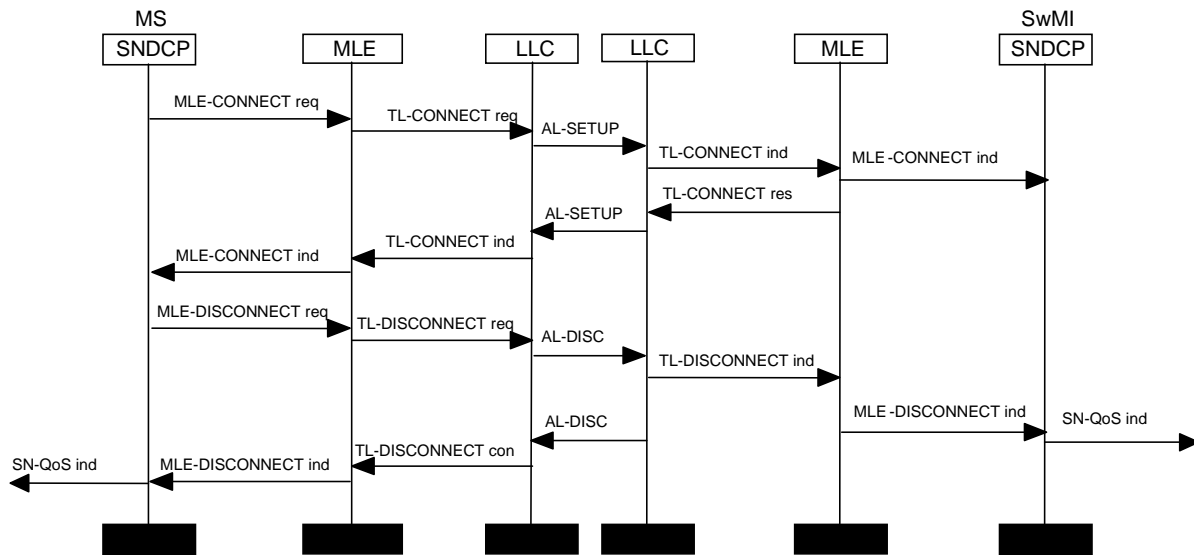

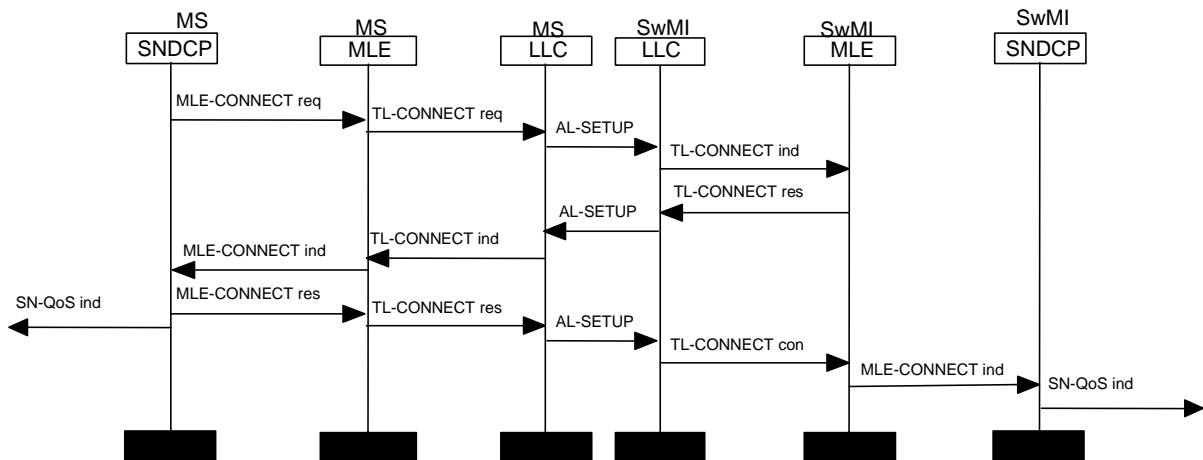

Figure 28.24: Failed advanced link setup - too low advanced link QoS offered by SwMI

Figure 28.25 shows the case where the establishment of the advanced link succeeds, after the MS accepts a lower advanced link QoS than that originally requested.

**Figure 28.25: Successful advanced link setup - lower advanced link QoS accepted**

#### b) Resetting an active advanced link

At any time both peer entities, MS and SwMI, may reset an advanced link in order to change the advanced link QoS parameters.

NOTE 5: The SwMI should not reset the advanced link QoS number of  $\pi/4$ -DQPSK timeslots per TDMA frame to a higher value than the last received advanced link setup initiated by the MS i.e. the upwards advanced link QoS negotiation should be limited to the value indicated by the MS.

NOTE 6: If the MS is on a phase modulation PDCH, the SwMI may temporarily provide fewer or more timeslots per TDMA frame than were negotiated in the advanced link setup. This is indicated in the channel allocation information element and does not thus need advanced link reset. This is, however, against the advanced link QoS negotiation and should be used only because the SwMI temporarily does not have suitable resources for matching the advanced link QoS demand. The SwMI should provide the number of phase modulation timeslots per TDMA frame that was negotiated as soon as conditions permit. If there is a permanent lack of resources, the advanced link may be reset to fewer timeslots per TDMA frame. If the MS is not using a phase modulation PDCH at the time that the SwMI resets the advanced link, the SwMI is not required to take account of any resources that were negotiated in the preceding advanced link setup.

NOTE 7: If QoS was negotiated during PDP context activation, the MS or SwMI should change the QoS by modifying the PDP context (see clause 28.3.3.5a).

#### c) MS returns from READY Temporary Break state after recovering from cell reselection

The MS SNDCP entity shall re-establish the acknowledged advanced links if the following three conditions are true:

- 1) The MS SNDCP entity is in READY Temporary Break state and receives a MLE-RESUME indication primitive from the MLE.
- 2) There are SN-DATA PDUs pending for transmission.
- 3) The MS does not support advanced link roaming (see clause 28.3.4.4).

Where a MS SNDCP entity, which is in READY Temporary Break state, receives a MLE-RESUME indication primitive from the MLE, it is the responsibility of the MS SNDCP entity to firstly notify the SwMI SNDCP entity that it has regained access to the underlying resources (e.g. cell reselection has completed). This notification is carried out by sending a SN-RECONNECT PDU on the uplink.

NOTE 8: This SN-RECONNECT PDU is of most use when a SwMI is engaged in data transfer on the downlink to a MS and the MS switches cell. The SN-RECONNECT PDU is an efficient means by which the SwMI SNDCP entity can discover the cell change and re-route data accordingly.

If the MS has pending SN-DATA or SN-UNITDATA PDUs for a single NSAPI, the MS shall include that NSAPI in the "NSAPI" information element of the SN-RECONNECT PDU and shall set the "data to send" information element to indicate "SN-DATA PDU or SN-UNITDATA PDU awaiting transmission on uplink".

If the MS has pending SN-DATA or SN-UNITDATA PDUs for more than one NSAPI, the MS shall include an NSAPI with pending SN-DATA or SN-UNITDATA PDUs in the "NSAPI" information element of the SN-RECONNECT PDU and shall set the main "data to send" information element to indicate "SN-DATA PDU or SN-UNITDATA PDU awaiting transmission on uplink". (Note that there are supplementary "data to send" information elements in the "NSAPI for reconnection" information element.) The MS may include the NSAPIs of the remaining PDP contexts with active CONTEXT\_READY timers in the "NSAPI for reconnection" information element. The SwMI should regard the NSAPI in the "NSAPI" information element as having higher priority than the NSAPIs in the "NSAPI for reconnection" information element. The SwMI should regard the NSAPIs in the "NSAPI for reconnection" element as having been sent in order of priority, most important first.

NOTE 9: In both the above cases, the MS is not precluded from including the same NSAPI in both the "NSAPI" information element and the "NSAPI for reconnection" information element (though there is no purpose for this in the present document). If this occurs, the SwMI should ignore the second instance of the same NSAPI. (It is intended that in a future version of the present document the SwMI should use the additional information about the NSAPI in the "NSAPI for reconnection" information element when the same NSAPI is included in both information elements.)

The SN-RECONNECT PDU shall be transmitted using the acknowledged basic link service. The SN-RECONNECT PDU includes a main "data to send" information element which indicates if the MS has SN-DATA or SN-UNITDATA PDUs awaiting transmission and includes further "data to send" information elements in the "NSAPI for reconnection" information element (if present). Upon successful transmission of the SN-RECONNECT PDU with the main "Data to Send" = 0 (thus indicating that the MS has no data to send), the MS shall stop the READY timer, shall stop any CONTEXT\_READY timers, shall start the STANDBY timer and shall enter state STANDBY. Upon successful transmission of the SN-RECONNECT PDU with the main "data to send" = 1 (thus indicating that the MS has data to send), the MS shall stop the READY timer, shall stop any CONTEXT\_READY timers, shall start the STANDBY and RESPONSE\_WAIT timers and shall enter state RESPONSE-WAITING. On reception of the SN-RECONNECT PDU, the SwMI SMDCP entity shall stop the READY timer and any CONTEXT\_READY timers, start the STANDBY timer and enter state STANDBY. The SwMI SMDCP entity shall check if the MS has indicated within the SN-RECONNECT PDU that it has a pending SN-DATA or SN-UNITDATA PDU for transfer on the uplink. The SwMI SMDCP shall also check to see if there is a pending SN-DATA PDU or SN-UNITDATA PDU for transfer on the downlink. The message (if any), sent on the downlink by the SMDCP entity is shown in table 28.18.

**Table 28.18: Message sent by SwMI in response to SN-RECONNECT from MS**

| MS has SN-DATA PDU or SN-UNITDATA PDU pending | SwMI has SN-DATA or SN-UNITDATA PDU pending | SwMI response             |
|---|---|---------------------------|
| No  | No  | no response               |
| Yes   | No  | SN-DATA TRANSMIT RESPONSE |
| No  | Yes   | SN-DATA TRANSMIT REQUEST  |
| Yes   | Yes   | SN-DATA TRANSMIT RESPONSE |

NOTE 10: The MS is not precluded from setting "data to send" if it wishes to be on a PDCH because it expects imminent reception of data on the downlink or imminent arrival of data for transmission on the uplink.

The SwMI may include a channel allocation in the SN-DATA TRANSMIT REQUEST or SN-DATA TRANSMIT RESPONSE PDU, sending the MS to the PDCH. The SN-DATA TRANSMIT REQUEST or SN-DATA TRANSMIT RESPONSE PDU shall include the NSAPI or NSAPIs that the SwMI has successfully reconnected.

NOTE 11: The SwMI is not precluded from including the same NSAPI in both the "NSAPI" information element and the "NSAPI additional" information element (though there is no purpose for this in the present document). If this occurs, the MS should ignore the second instance of the same NSAPI. (It is intended that in a future version of the present document the MS should use the additional information about the NSAPI in the "NSAPI additional" information element when the same NSAPI is included in both information elements.)

The MS shall start the READY timer and shall (if supported) start the CONTEXT\_READY timers of those PDP contexts included in the SN-DATA-TRANSMIT REQUEST or SN-DATA-TRANSMIT RESPONSE PDU. Once on the PDCH, the MS shall re-establish the advanced links that it has assigned to the PDP contexts identified by the NSAPIs included in the SN-DATA TRANSMIT REQUEST or SN-DATA TRANSMIT RESPONSE PDU.

If, while awaiting a response to an SN-RECONNECT PDU, the MS SNDCP receives an SN-DATA TRANSMIT RESPONSE PDU with Accept/Reject = 0 or the RESPONSE\_WAIT timer expires, the MS SNDCP shall stop the RESPONSE\_WAIT timer, issue MLE-RELEASE request primitives asking MLE to locally disconnect the advanced links and shall enter STANDBY state.

NOTE 12: For direct access, the BS always supports the SNDCP service when the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU indicates "normal mode" (system wide services supported); see clause 18. A direct access MS may send an SN-RECONNECT PDU to the SwMI while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDUs is indicating "system wide services temporarily not supported"; however the BS in this mode may temporarily not support the SNDCP service, in which case the BS may send the SN-DATA TRANSMIT RESPONSE PDU with reject cause "SNDCP service temporarily not available".

A conventional access MS is not permitted to send the SN-RECONNECT PDU while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDCP service is not available on this cell".

NOTE 13: The MS is not permitted to send the SN-RECONNECT PDU on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

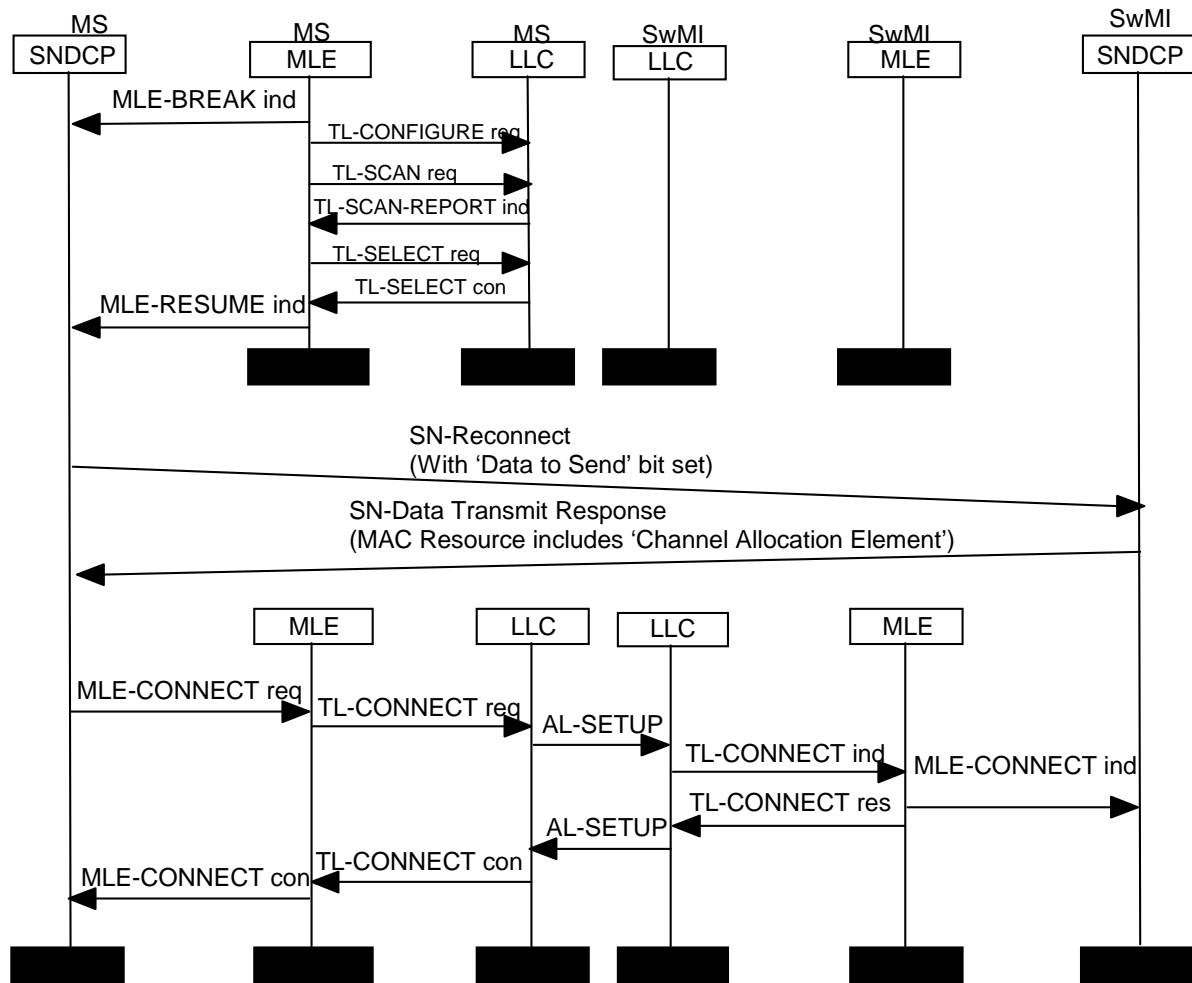

Figure 28.26 presents the case where the MS has data to send and re-establishes the advanced link once on the PDCH.

In this case, the MS SNDCP entity is in state READY Temporary Break and receives a MLE-RESUME indication primitive from the MLE, thus indicating that access to the communication resources has become available again. It sends a SN-RECONNECT PDU to the SwMI SNDCP entity, stops the READY timer, stops all CONTEXT\_READY timers, starts the STANDBY and RESPONSE\_WAIT timers and enters RESPONSE-WAITING state. On reception of the SN-RECONNECT PDU, the SwMI stops the READY timer and any CONTEXT\_READY timers, starts the STANDBY timer and enters STANDBY state. The SwMI on seeing that the MS has indicated in the SN-RECONNECT PDU that it has a SN-DATA or SN-UNITDATA PDU awaiting transfer on the uplink, shall respond with a SN-DATA TRANSMIT RESPONSE PDU.

The SN-DATA TRANSMIT RESPONSE PDU may be sent using the acknowledged basic link service or the unacknowledged basic link service. Where the MS (after recovering from the radio downlink failure) is on a common control channel (MCCH or MCCH-Q or common SCCH), the MAC-RESOURCE PDU which contains this message shall (unless the current channel is suitable) either include a "Channel Allocation" information element which directs the MS to a PDCH chosen by the SwMI (taking into account the MS's declared capabilities and negotiated or default QoS requirements), or, if requested by the "resource request" information element in the SN-RECONNECT PDU, shall include a "Channel Allocation" information element which should direct the MS to a single-slot or multi-slot phase modulation PDCH within the MS's declared capabilities (see clause 28.3.4.8). On transmission of the SN-DATA TRANSMIT RESPONSE PDU, the SwMI shall stop the STANDBY timer, start the READY timer and enter READY state. The SwMI may start CONTEXT\_READY timers (see clause 28.2.6.2). On reception of the SN-DATA TRANSMIT RESPONSE PDU, the MS shall stop the STANDBY and RESPONSE\_WAIT timers, start the READY timer, shall, if supported, start CONTEXT-READY timers for the indicated PDP contexts, and shall enter READY state.

NOTE 14: The MS's default QoS requirements are for background class data with unspecified throughput, delay and reliability.

On the PDCH, the MS shall re-establish the advanced links assigned to the PDP contexts which have data waiting to be sent. This is achieved through the sending of MLE-CONNECT request primitives to the MLE. Within the MAC-ACCESS PDU used to carry the AL-SETUP PDU on the uplink, the MS may include a "Reservation Requirement" information element for the total number of timeslots needed to transfer any pending data. The MAC-RESOURCE PDU used to carry the AL-SETUP PDU response on the downlink may include a "Slot Granting" information element to reserve timeslots for the MS on the uplink. Also, the SwMI may alter the capacity of the PDCH by including in the MAC-RESOURCE PDU a "Channel Allocation" information element with "allocation type" = 00 - see clause 23.5.4.2.1 and its clauses of the present document. (For example, the SwMI could decide to alter the number of timeslots per TDMA frame of a phase modulation PDCH depending on the number of  $\pi/4$ -DQPSK timeslots per TDMA frame requested by the MS in an AL-SETUP PDU. Or the SwMI could move the MS from a QAM PDCH to a phase modulation PDCH within the MS's declared capabilities if the MS requests a phase modulation connection in an AL-SETUP PDU sent on the QAM PDCH).

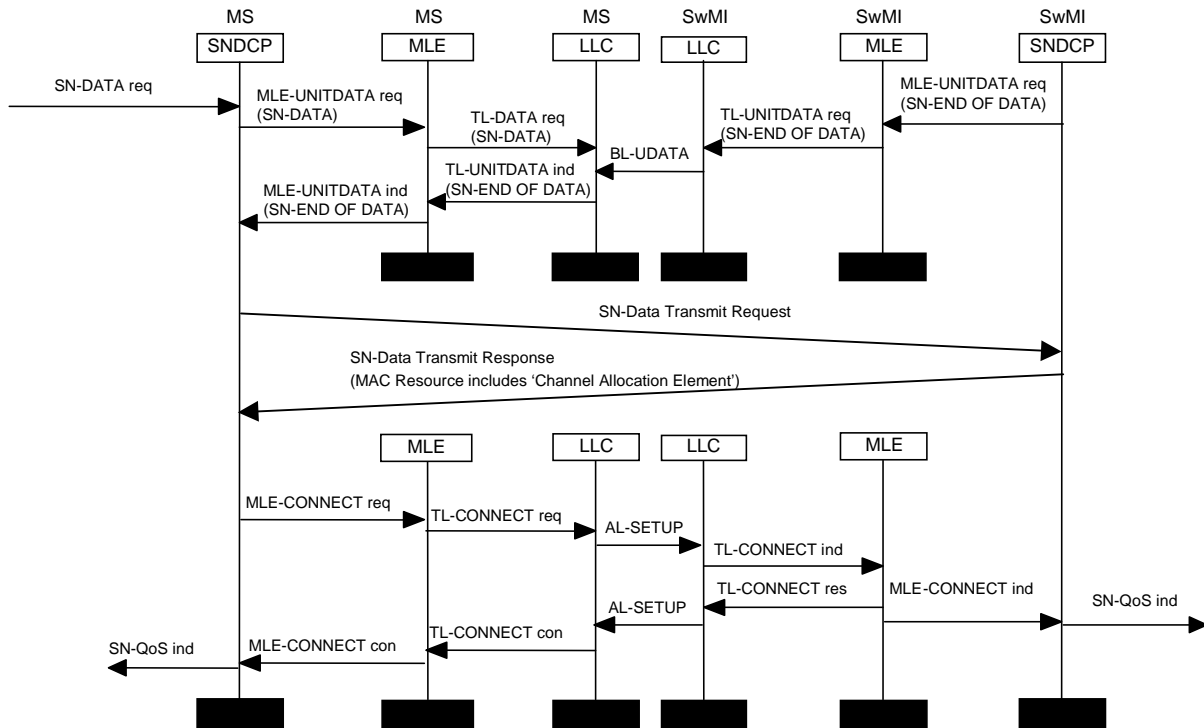

**Figure 28.26: Advanced link set up after a radio downlink failure, with MS in READY state**

d) Failure to send a N-PDU

After receiving an MLE-REPORT indication primitive indicating failure sending a N-PDU the MS or SwMI shall reset the relevant advanced link. This reset is required by the SNDCP user application and compression mechanisms expecting a reliable link. This link reset is required when even a single N-PDU is lost. This applies for both the MS and SwMI i.e. the SwMI should reset the relevant advanced link when it recognizes failure sending a N-PDU.

Where the MS SNDCP entity receives a SN-END OF DATA PDU from the SwMI (effectively moving the MS off the PDCH), prior to reception of a MLE-REPORT indicating whether the transmission of a SN-DATA or SN-UNITDATA PDU was successful or not, then the MS shall reset the assigned advanced link (SN-DATA PDU only) and notify the service user, with a SN-DELIVERY indication primitive, of the failure to send the SN-DATA or SN-UNITDATA PDU. This scenario is shown in figure 28.27.

In the example, a MS passes a SN-DATA PDU to the lower layers. It then receives a SN-END OF DATA from the peer SNDSCP entity in the SwMI. As the MS SNDSCP has not yet had confirmation (in the form of a MLE-REPORT indication primitive) that the previous SN-DATA was successfully transmitted, it resets the assigned advanced link. Before sending the AL-SETUP PDU with a reason "Reset", the MS sends SN-DATA TRANSMIT REQUEST PDU to the SwMI in order to get to the PDCH where it can re-establish the assigned advanced link.

**Figure 28.27: Resetting advanced link after reception of SN-END OF DATA PDU prior to completing transfer of previous SN-DATA PDU**

#### e) Return from circuit mode call

In an alternating voice and data communication a MS can be offered a group call on the PDCH and the MS may accept the group call. The MS may want to return to the interrupted PDCH communication and the MS SNDSCP entity may notify the SwMI SNDSCP entity that it is again available. In case the MS has no data to send this notification is carried out by sending a SN-RECONNECT PDU on the uplink; if the MS has data to send then it is done with SN-TRANSMIT REQUEST PDU when the SERVICE\_CHANGE timer is inactive.

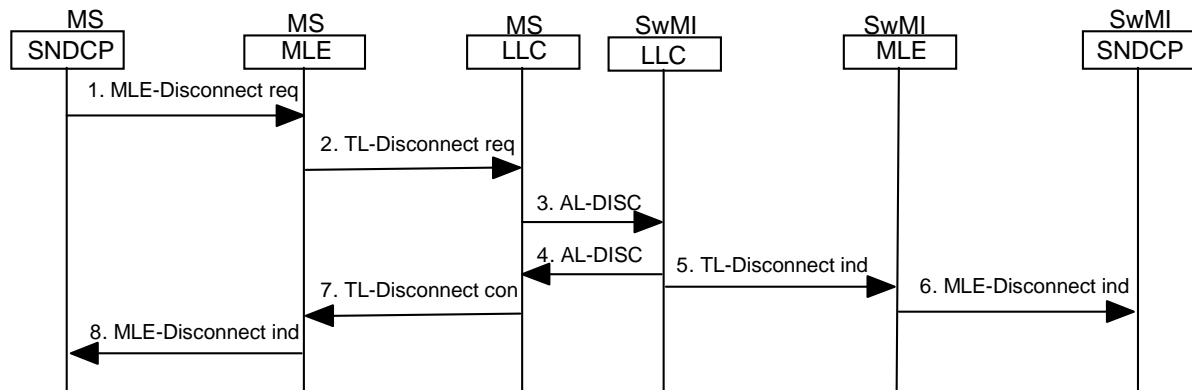

If the MS supports and needs to reconnect advanced link after return from the voice call, then clause 28.3.4.4 is applicable.

#### 28.3.4.3 Logical Link disconnection

An acknowledged advanced link is disconnected before the deactivation of the last PDP context assigned to that advanced link, as shown in figure 28.28. The disconnection is triggered by the MS. In case of MS originated PDP context deactivation procedure (e.g. the SN-SAP user has triggered PDP context deactivation by issuing SN-NSAPI DEALLOC request primitive), the MS shall first disconnect the advanced link explicitly and after advanced link disconnection start the actual PDP context deactivation procedure as defined in clause 28.3.3.6.1. In case of SwMI originated PDP context deactivation procedure, the MS shall trigger advanced link disconnection in reception of a SN-DEACTIVATE PDP CONTEXT DEMAND PDU from the SwMI and shall not respond by a SN-DEACTIVATE PDP CONTEXT ACCEPT PDU until advanced link is explicitly disconnected.

NOTE 1: If the MS has initiated the advanced link disconnection, it should not accept packet data service any more for PDP contexts assigned to that link.

NOTE 2: In case the STANDBY timer expires, the advanced links may be exceptionally released implicitly without sending AL-DISC PDUs.

**Figure 28.28: Disconnecting advanced link before the last PDP context deactivation**

#### 28.3.4.4 Advanced link reconnection

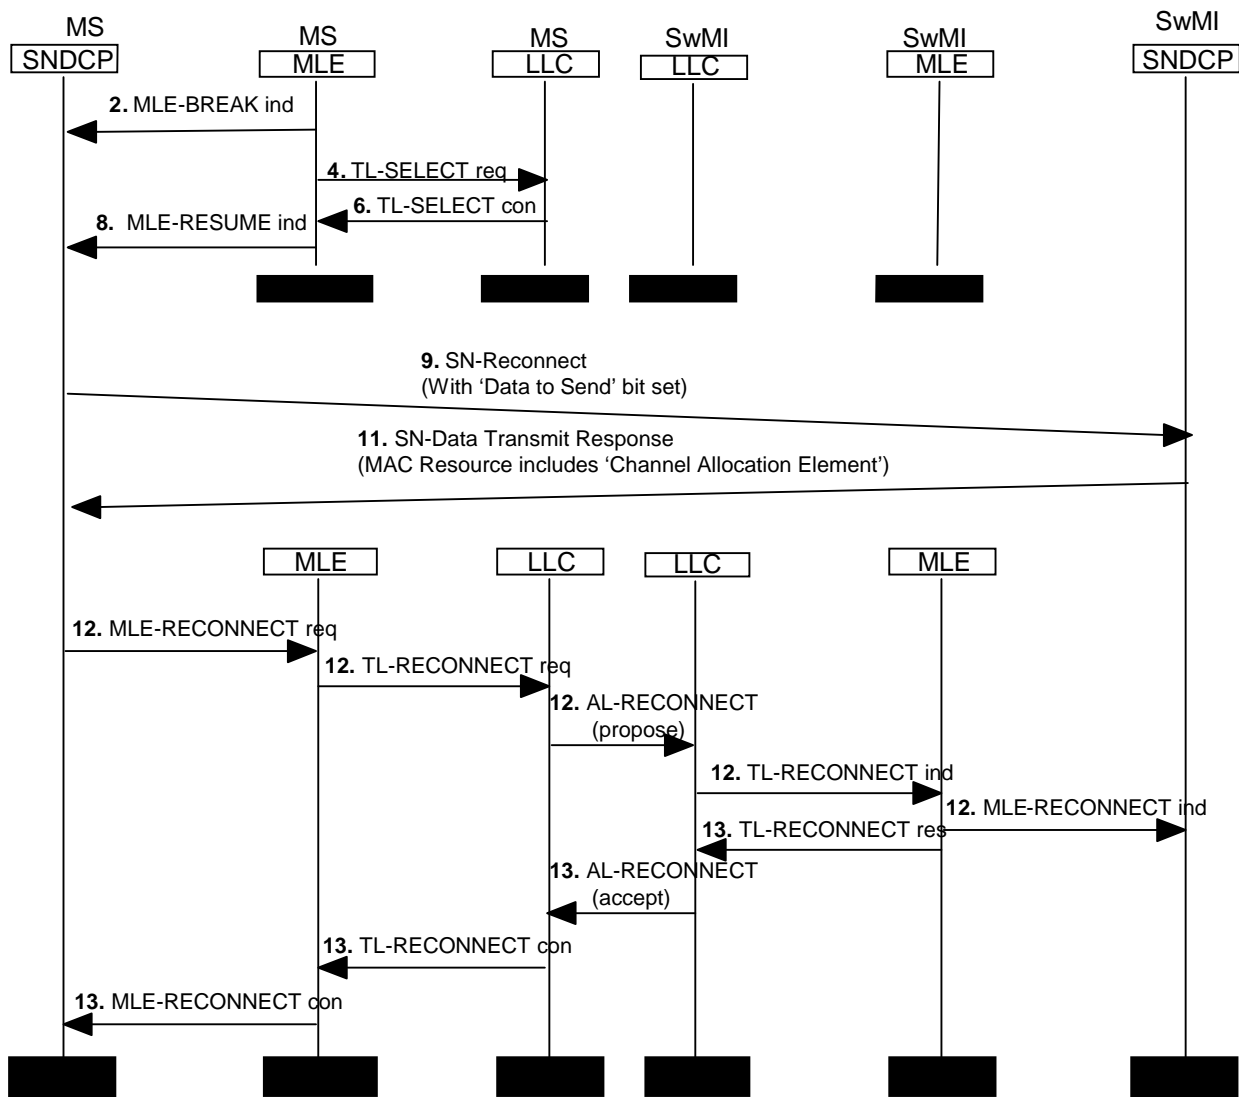

In an attempt to improve the performance of packet data transfer during cell reselection, a SwMI may allow a MS to maintain its advanced link as it roams between cells. The ability for a MS to continue using an advanced link on a new cell with all parameters, variables and timers carried from the previous cell is called advanced link roaming. It is optional for a MS or SwMI to support advanced link roaming. Advanced link roaming is initiated by the MS, by requesting the reconnection of an advanced link on the new cell. The SwMI shall respond to this request by indicating if the request has been accepted or rejected. The reconnection of an advanced link shall only be initiated by the MS. The MS SNDCP entity shall only attempt to reconnect an advanced link if the following two events have occurred:

- 1) The MS SNDCP entity has transmitted a SN-RECONNECT PDU after successful cell handover.
- 2) The MS has received a SN-DATA TRANSMIT RESPONSE PDU accepting the request or a SN-DATA TRANSMIT REQUEST PDU in response to the SN-RECONNECT PDU and moved to the PDCH.

If both the above are true and the MS supports advanced link roaming, then the MS SNDCP entity may issue a MLE-RECONNECT request primitive to the MLE which shall be forwarded to the LLC as a TL-RECONNECT request primitive. The LLC shall build an AL-RECONNECT PDU with reconnect report value "propose" and send it to the SwMI. If the SwMI recognizes the AL-RECONNECT PDU it shall respond with an AL-RECONNECT PDU. In this PDU the SwMI shall indicate if it supports advanced link roaming or not by the reconnect report value "accept" or "reject" respectively. Reception of the AL-RECONNECT PDU from the SwMI shall result in the MS LLC passing a TL-RECONNECT confirm primitive to the MLE and in turn a MLE-RECONNECT confirm primitive being passed to the SNDCP entity. Based on the response from the SwMI, the MS SNDCP entity at this point will know if the advanced link has been successfully reconnected or not. Where multiple acknowledged advanced links are in use, the MS SNDCP may attempt to reconnect each by issuing successive MLE-RECONNECT request primitives to the MLE. The MS SNDCP does not need to await the arrival of a MLE-RECONNECT confirm primitive for one advanced link before sending an MLE-RECONNECT request primitive for another advanced link.

Refer to clause 28.3.4.6 on the channel change protocol.

Figure 28.29 presents the case where both the MS and SwMI support advanced link roaming and where the MS is in ready state with data to transmit when the cell reselection procedures begin.

NOTE: Each message number in the figure above has a number associated with it which corresponds to the numbers of the bullet points in the description below.

**Figure 28.29: Successfully reconnecting an advanced link after cell reselection. Both MS and SwMI support advanced link roaming**

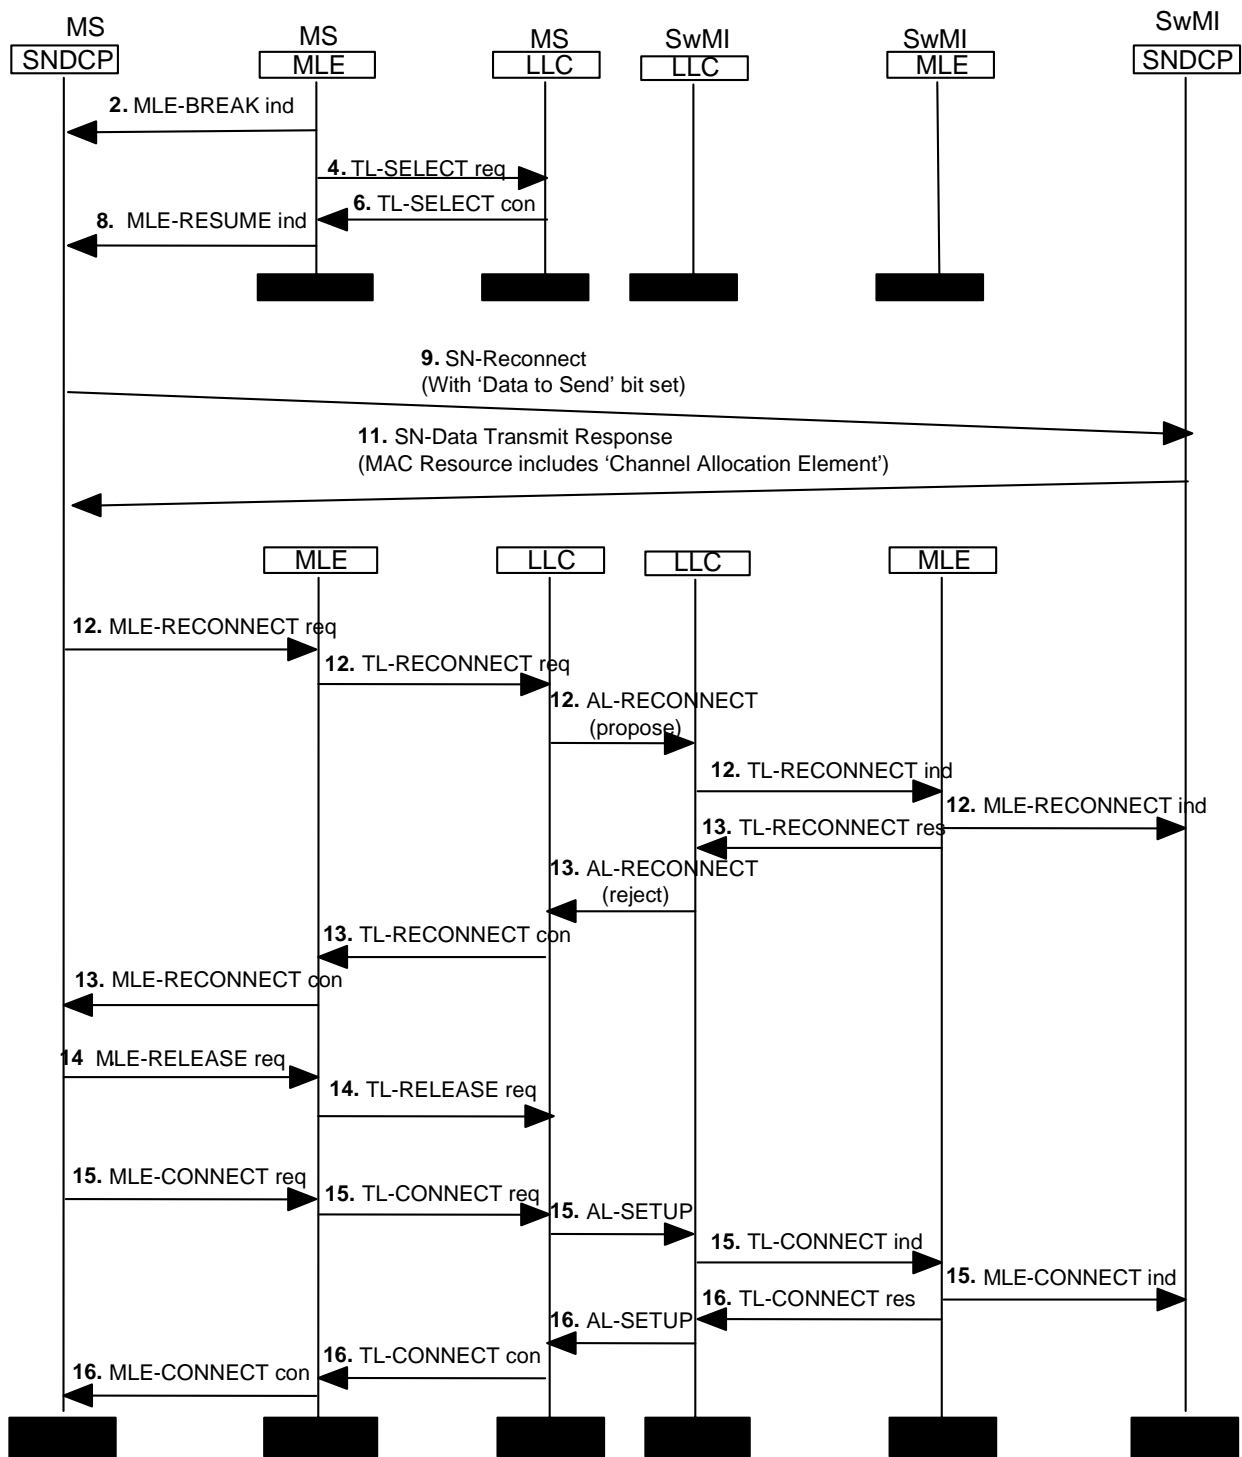

1. Signal quality begins to fall -> MLE decides to switch cell.
2. MLE sends MLE-BREAK indication primitive to SNDCP.
3. As the MS supports advanced link roaming, the MLE will not disconnect the advanced links (i.e. a TL-RELEASE request primitive is not sent to the LLC). The MS SNDCP enters the READY-temporary break state from the READY state.
4. MLE sends TL-SELECT request primitive to the LLC requesting the MAC to switch to the main carrier of the new cell.
5. LLC forwards this as a TMC-SELECT request primitive to the MAC (not shown).
6. The MAC switches to the MCCH or MCCH-Q (or common SCCH) of the new cell and issues a TMC-SELECT confirm primitive to the LLC which is then passed to the MLE as a TL-SELECT confirm primitive.
7. MM performs registration (V+D) and authentication if required (not shown).

8. MLE sends MLE-RESUME indication primitive to SNDCP.
9. SNDCP sends a SN-RECONNECT PDU to the SwMI. If there is data awaiting transmission in the SNDCP buffer, or if the SNDCP entity is aware that a partially transmitted TL-SDU is in the LLC buffers (i.e. one which has not yet been fully transmitted or one for which an acknowledgement has not yet been received from the peer entity), then the "Data to Send" field in the SN-RECONNECT PDU will be set to True else the "Data to Send" field will be set to False. In this case the Data to Send field is set to True.
10. The MS SNDCP entity enters RESPONSE-WAITING state, stops the READY timer, stops all CONTEXT\_READY timers and starts the STANDBY and RESPONSE-WAIT timers.
11. On reception of a SN-DATA TRANSMIT RESPONSE PDU from the SwMI, the MS shall switch to the PDCH and enter READY state.

NOTE 1: If for some reason the MS does not receive a SN-DATA TRANSMIT RESPONSE PDU prior to the RESPONSE\_WAITING timer expires or if a SN-DATA TRANSMIT RESPONSE PDU is received with Accept/Reject = 0 (i.e. requested is rejected), then SNDCP should attempt to initiate local disconnection of the advanced links.

12. SNDCP requests that an acknowledged advanced link is reconnected by passing MLE-RECONNECT request primitive to the MLE which in turn passes a TL-RECONNECT request primitive to the LLC. The LLC sends an AL-RECONNECT PDU with the reconnect report set to "propose" to the SwMI.
13. The SwMI responds with an AL-RECONNECT PDU, indicating that advanced link roaming is supported by setting the reconnect report set to "accept". The MS may now continue transmitting or receiving LLC segments for that advanced link from where it left off on the previous cell. If SNDCP possesses activated PDP contexts assigned to other acknowledged advanced links, the MS SNDCP may attempt to reconnect those links by issuing further MLE-RECONNECT request primitives (not shown in figure 28.29).

Figure 28.30 presents the case where the MS attempts to reconnect an advanced link on the new cell, but the SwMI rejects this request.

**Figure 28.30: Failure to reconnect the advanced link after cell reselection. SwMI does not support advanced link roaming**

1. Signal quality begins to fall -> MLE decides to switch cell.
2. MLE sends MLE-BREAK indication primitive to SNDCP.
3. As the MS supports advanced link roaming, the MLE will not disconnect the advanced links (i.e. no TL-RELEASE request primitives are sent to the LLC). The MS SNDCP enters the READY-temporary break state from the READY state.

4. MLE sends TL-SELECT request primitive to the LLC requesting the MAC to switch to the main carrier of the new cell.
5. LLC forwards this as a TMC-SELECT request primitive to the MAC (not shown).
6. The MAC switches to the MCCH or MCCH-Q (or common SCCH) of the new cell and issues TMC-SELECT confirm primitive to the LLC which is then passed to the MLE as a TL-SELECT confirm primitive.
7. MM performs registration (V+D) and authentication if required (not shown).
8. MLE sends MLE-RESUME indication primitive to SNDCP.
9. SNDCP shall send a SN-RECONNECT PDU to the SwMI. If there is data awaiting transmission in the SNDCP buffer, or if the SNDCP entity is aware that a partially transmitted TL-SDU is in the LLC buffers (i.e. one which has not yet been fully transmitted or one for which an acknowledgement has not yet been received from the peer entity), then the "Data to Send" field in the SN-RECONNECT PDU will be set to True. Else the "Data to Send" field will be set to False. In this case it is assumed the Data to Send field is set to True.
10. The MS SNDCP entity enters RESPONSE-WAITING state, stops the READY timer, stops all CONTEXT\_READY timers and starts the STANDBY and RESPONSE-WAIT timers.
11. On reception of a SN-DATA TRANSMIT RESPONSE PDU from the SwMI, the MS shall switch to the PDCH and enter READY state.

NOTE 2: If for some reason the MS does not receive a SN-DATA TRANSMIT RESPONSE PDU prior to the RESPONSE\_WAITING timer expires or if a SN-DATA TRANSMIT RESPONSE PDU is received with Accept/Reject = 0 (i.e. requested is rejected), then SNDCP should attempt to initiate local disconnection of the advanced link.

12. SNDCP requests that the advanced link is reconnected by passing MLE-RECONNECT request primitive to the MLE which in turn passes a TL-RECONNECT request primitive to the LLC. The LLC sends an AL-RECONNECT PDU to the SwMI with the reconnect report set to "propose". If SNDCP possesses PDP contexts assigned to other acknowledged advanced links, the MS may also attempt to reconnect each of those links by issuing further MLE-RECONNECT request primitives (not shown in figure 28.30).
13. The SwMI responds with an AL-RECONNECT PDU, indicating that advanced link roaming is not supported for the indicated link by setting the reconnect report to "reject".
14. In order to reset the LLC advanced link state machine, the SNDCP entity shall pass a MLE-RELEASE request primitive to the MLE which in turn passes a TL-RELEASE request primitive to the LLC.
15. The SNDCP entity now requests that the advanced link is reset by passing MLE-CONNECT request primitive to the MLE which in turn passes a TL-CONNECT request primitive to the LLC. The LLC sends an AL-SETUP PDU to the SwMI.
16. The SwMI responds with an AL-SETUP PDU indicating the resetting of the advanced link. The MS may now begin transmitting or receiving packet data.

#### 28.3.4.5 Releasing the advanced link

Where a MS does support advanced link roaming, and where the SNDCP entity receives a MLE-BREAK indication primitive while in standby state, then on reception of a corresponding MLE-RESUME indication primitive, the SNDCP entity shall locally disconnect all existing advanced links by issuing MLE-DISCONNECT request primitives to the MLE.

#### 28.3.4.6 Physical channel handling

In the TETRA protocol model MAC layer may request upper layers to decide whether a physical channel change is performed as proposed by BS to support a network layer service. This allows application layers to negotiate which service is selected when there is a conflict between various services e.g. ongoing speech service and packet data service. The details of the negotiation are outside the scope of the present document. The MLE layer provides the channel change request to the SNDCP as a "channel change response required" parameter set to "true" in conjunction with a "Channel change handle" parameter, refer to clause 17.3.5.

If the channel change is acceptable on all services point of view the SNDCP shall respond to that request by issuing an MLE-CONFIGURE request primitive containing a "channel change accepted" parameter set to "accept". In the SNDCP protocol descriptions this is implied by requirements such as "the MS shall switch to the PDCH".

In the special case that the "channel change response required" parameter set to "true" is delivered to the MS SNDCP in an MLE-UNITDATA indication primitive that contains a group addressed SN-END OF DATA PDU when the READY timer is active, the MS SNDCP shall respond by issuing an MLE-CONFIGURE request primitive containing a "channel change accepted" parameter set to "ignore".

In all other cases where the channel change is not acceptable, the MS SNDCP shall respond to an MLE primitive containing a "channel change response required" parameter set to "true" by issuing an MLE-CONFIGURE request primitive with the "channel change accepted" parameter set to "reject".

#### 28.3.4.7 Loss of Radio Resource

On reception of an MLE-CONFIGURE indication primitive advising "loss of radio resources":

- if data priority is supported by the MS, the MS SNDCP shall inform MLE that the MS default data priority is "not applicable" using the MLE-CONFIGURE request primitive;
- if there is data awaiting transmission, including where the MS SNDCP entity is aware that a partially transmitted N-PDU is in the LLC buffers (i.e. one which has not yet been fully transmitted or one for which an acknowledgement has not yet been received from the peer entity), then the MS SNDCP entity shall send to the SwMI a SN-RECONNECT PDU with the field "Data to Send" set to 1, shall start the RESPONSE\_WAIT timer and shall enter the READY-temporary break state;
- if there is no data awaiting transmission, the MS SNDCP entity shall send to the SwMI a SN-RECONNECT PDU with the field "Data to Send" set to 0, shall stop the READY timer and any CONTEXT\_READY timers, start the STANDBY timer and enter STANDBY state.

NOTE: The "loss of radio resources" indication means that the PDCH has failed, and that the MS has been moved back to the common control channel (MCCH or MCCH-Q or common SCCH). The MS attempts to transmit the SN-RECONNECT PDU on the common control channel.

#### 28.3.4.8 Selection of physical channel

See also clause 28.3.4.2 on logical link setup and clause 28.3.5.2a on usage of the "resource request" information element.

When an MS indicates to the SwMI that it wishes to transmit or receive SN-DATA or SN-UNITDATA PDUs by sending an SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU on the uplink, or if the SwMI wishes to transmit SN-DATA or SN-UNITDATA PDUs to an MS, the SwMI should assign the MS to a suitable PDCH within the MS's declared capabilities (see note 1) if the current physical channel is not suitable. This also applies if the MS-MLE requests a change to a new assigned channel when the MS is already using a PDCH (see clause 18.3.4.9). The SwMI may also assign the MS to a new PDCH following advanced link negotiation on an existing PDCH (see clause 28.3.5.2a), following successful modification of a PDP context, or following successful reactivation of an already-activated PDP context.

NOTE 1: The MS's declared capabilities comprise the information the MS sent to the SwMI in a recent successful registration request that included a "class of MS" and, optionally, an "extended capabilities" information element (see clauses 16.4.1.1 to 16.4.3). The relevant information concerns single-slot or multi-slot capabilities, and supported modulation types and RF bandwidths. If the MS included a "resource request" information element in the SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU, the MS's declared capabilities also include the contents of the "full phase modulation capability" information element in the "resource request" information element. If the SwMI wishes to allocate a phase modulation channel with more timeslots than the requested number of timeslots per TDMA frame, the SwMI should use the capabilities information in the "resource request" information element to determine the maximum number of phase modulation timeslots per TDMA frame that the MS can use on  $\pi/4$ -DQPSK channels, and on D8PSK channels if the MS supports the D8PSK modulation mode.

The SwMI chooses a suitable physical channel as follows:

- if QoS was not negotiated for a PDP context, the SwMI should assume by default that this PDP context is required for background class data with unspecified throughput, delay and reliability;
- if a  $\pi/4$ -DQPSK single-slot channel was indicated in the "resource request" information element of an SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU, the SwMI should choose a single slot phase modulation PDCH within the MS's declared capabilities. If a suitable single-slot phase modulation PDCH is not available, the SwMI should choose a multi-slot phase modulation PDCH within the MS's declared capabilities. If a phase modulation channel is not available and the MS is QAM-capable, the BS may choose a QAM PDCH within the MS's declared capabilities; or
- if a specific  $\pi/4$ -DQPSK multi-slot channel was indicated in the "resource request" information element of an SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU, the SwMI should choose a multi-slot phase modulation PDCH within the MS's declared capabilities with the number of timeslots per TDMA frame requested in the "resource request" information element. If a suitable multi-slot phase modulation PDCH with the requested number of timeslots per TDMA frame is not available, the SwMI should choose some other phase modulation PDCH within the MS's declared capabilities. If a phase modulation channel is not available and the MS is QAM-capable, the BS may choose a QAM PDCH within the MS's declared capabilities; or
- if an unspecified phase modulation resource was indicated in the "resource request" information element of an SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU, the SwMI should choose a phase modulation PDCH within the MS's declared capabilities. If a phase modulation channel is not available and the MS is QAM-capable, the BS may choose a QAM PDCH within the MS's declared capabilities;
- if a "resource request" was not included in the SN-DATA-TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU, or if SMDCP is in the READY state, the SwMI should choose a physical channel within the MS's declared capabilities which can satisfy the negotiated or default QoS requirements of the PDP contexts named in the SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU and the QoS requirements of all the MS's PDP contexts with active CONTEXT\_READY timers. The SwMI should take into account any advice from the MLE about which channels the MS can currently use that is included in the U-IRREGULAR CHANNEL ADVICE or U-CHANNEL CLASS ADVICE PDU (which may accompany the SN-DATA TRANSMIT REQUEST, SN-PAGE RESPONSE or SN-RECONNECT PDU) or in a U-CHANNEL REQUEST PDU.

NOTE 2: If an MS that supports phase modulation is unable to use the phase modulation channel it is allocated, the MS SMDCP may send the SwMI an SN-END OF DATA PDU indicating immediate service change followed by an SN-DATA-TRANSMIT REQUEST PDU that includes a resource request. Then it should start the RESPONSE\_WAIT timer and enter the RESPONSE-WAITING state. (This could occur if, for example, an MS that indicates it supports multi-slot phase modulation but is unable to use a four-slot phase modulation channel and does not send a "resource request" information element is allocated to a four-slot phase modulation channel.) Between sending the SN-END OF DATA PDU and receiving an acceptable response to its SN-DATA TRANSMIT REQUEST PDU (or receiving an SN-DATA TRANSMIT REQUEST PDU with an acceptable channel allocation) or receiving an SN-DATA TRANSMIT RESPONSE PDU that rejects the MS's request, or expiry of the RESPONSE\_WAIT timer, the MS should ignore any further SN-DATA TRANSMIT RESPONSE PDUs containing unusable channel allocations and should ignore any SN-END OF DATA PDUs that it may receive. (The window size is 1 for the acknowledged basic link, so the MS's SN-DATA TRANSMIT REQUEST PDU will not be transmitted until the MS has finished waiting for a layer 2 acknowledgement of the SN-END OF DATA PDU.)

NOTE 3: The SwMI should regard a resource request received on a QAM PDCH as a request for the MS to be moved to a phase modulation PDCH.

NOTE 4: In version 3.4.1 (and in earlier versions) [i.16] of the present document, an MS that did not negotiate QoS and did not include a "resource request" information element was assigned to a single-slot  $\pi/4$ -DQPSK PDCH. In this version of the present document, if the MS did not negotiate QoS during activation of a PDP context and does not include a "resource request" information element when commencing use of this PDP context, the SwMI chooses a PDCH based on the MS's declared capabilities and the default assumption that this PDP context is required for background class data with unspecified throughput, delay and reliability. Thus, an MS designed according to the present document that does not negotiate QoS will be unable to access D8PSK and QAM channels when using a SwMI that operates in accordance with version 3.4.1 (and earlier) [i.16] of the present document. An MS designed according to version 3.4.1 (or earlier) [i.16] that expects to be granted a single-slot  $\pi/4$ -DQPSK PDCH when it does not include a "resource request" information element may be sent to some other type of PDCH within its declared capabilities when using a SwMI that operates in accordance with the present document.

## 28.3.5 Packet Data transmission and reception procedures

### 28.3.5.0 General

This clause describes the procedures within SNDCP for transmitting and receiving packet data. Acknowledged and unacknowledged services are available for packet data transfer. This clause also defines compression techniques which may be used during data transfer as a way of improving efficiency.

#### 28.3.5.1 Acknowledged data service

The basic setting for sending N-PDUs between MS and SwMI is to use acknowledged service.

A scenario illustrating acknowledged data sending from SwMI to MS is shown in figure 28.31 (window size 1). Each numbered step is explained in the following list.

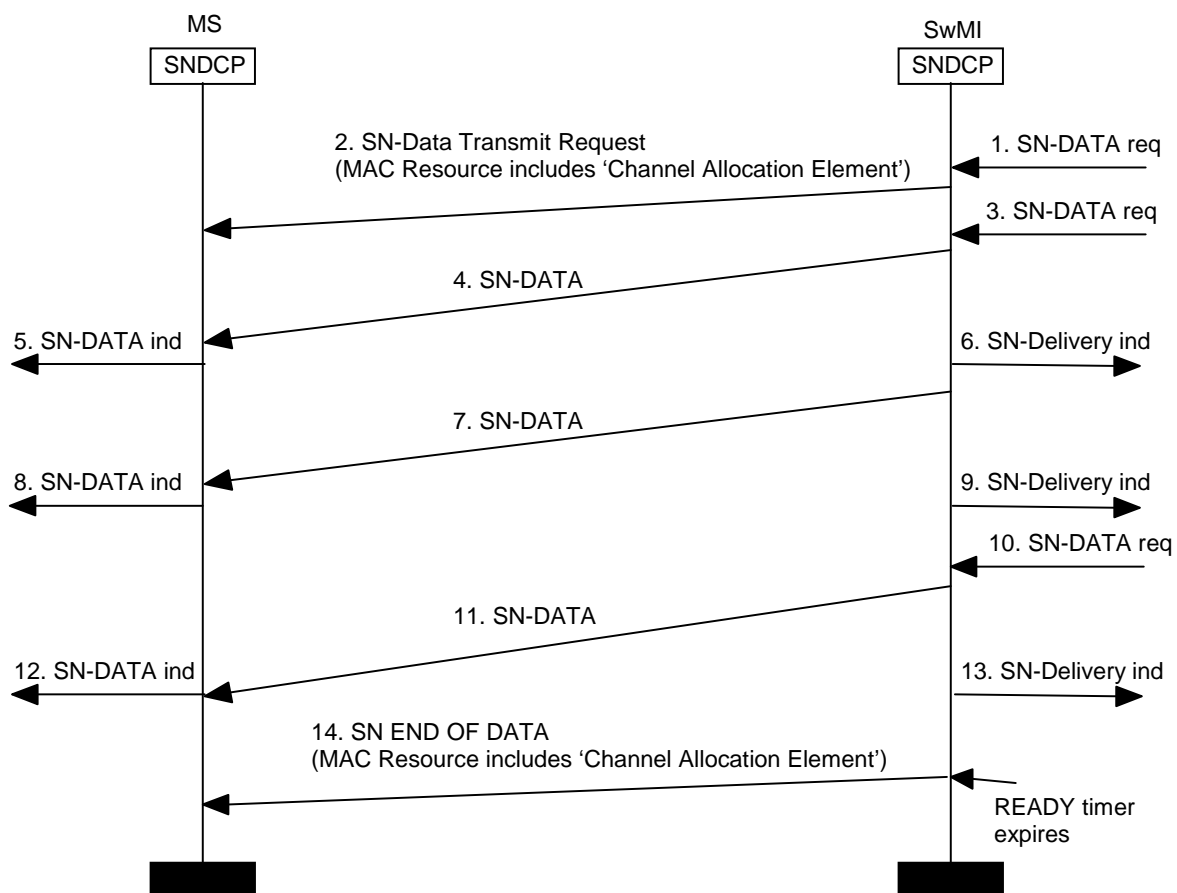

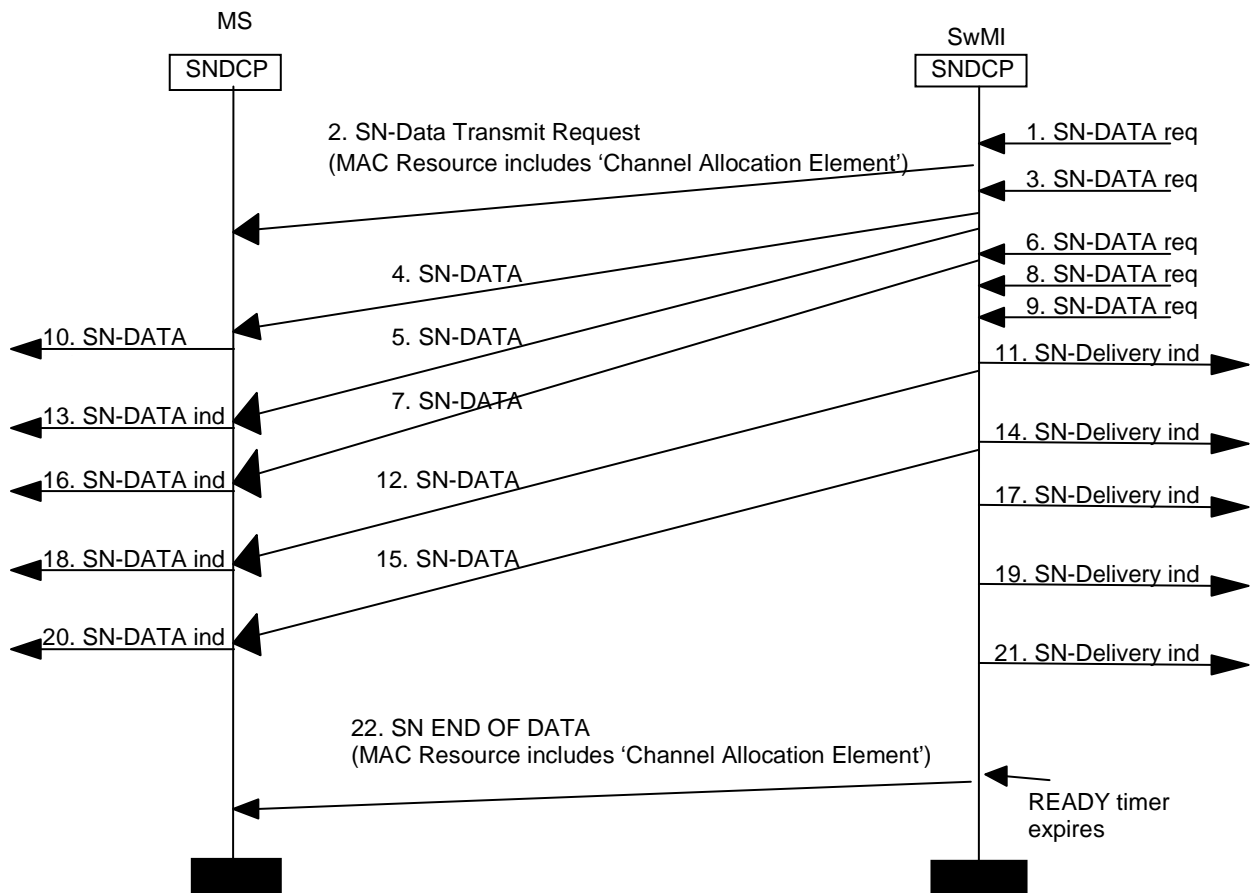

Figure 28.31: Acknowledged service, data from SwMI to MS

1. The SwMI SNDCP receives the first SN-DATA request primitive.
2. The SwMI SNDCP sends SN-DATA TRANSMIT REQUEST PDU. The request is sent by using the acknowledged or unacknowledged service (basic link) and the MAC-RESOURCE PDU contains a "Channel Allocation" information element sending the MS to a PDCH (the method of choosing the PDCH is given in clause 28.3.4.8). On transmission of the SN-DATA TRANSMIT REQUEST PDU, the SwMI stops the STANDBY timer, starts the READY timer, may start a CONTEXT\_READY timer (see clause 28.2.6.2) and enters state READY. On reception of the SN-DATA TRANSMIT REQUEST PDU, the MS stops the STANDBY timer, starts the READY timer, starts the CONTEXT\_READY timer for the PDP context referenced by the NSAPI parameter in the SN-DATA request primitive, and enters state READY.
3. The SwMI SNDCP receives the second SN-DATA request primitive.
4. The first N-PDU is sent to the MS by issuing SN-DATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN-DATA PDU was successfully transmitted by the lower layers, the SwMI SNDCP entity shall restart the READY timer and the CONTEXT\_READY timer (if used). At the MS the reception of the SN-DATA PDU shall result in the READY timer and, if supported, the CONTEXT\_READY timer being restarted.
5. After receiving the first SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
6. After receiving acknowledgement that the first SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
7. The second N-PDU is sent to the MS by issuing SN-DATA PDU. The READY timer is restarted in the SwMI SNDCP and in the MS SNDCP. The relevant CONTEXT\_READY timer is restarted in the MS SNDCP and, if used, in the SwMI SNDCP.
8. After receiving the second SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
9. After receiving acknowledgement that the second SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
10. The SwMI SNDCP receives the third SN-DATA request primitive.
11. The third N-PDU is sent to the MS by issuing SN-DATA PDU. The READY timer is re-started in the SwMI SNDCP and in the MS SNDCP. The relevant CONTEXT\_READY timer is restarted in the MS SNDCP and, if used, in the SwMI SNDCP.
12. After receiving the third SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing SN-DATA indication primitive.
13. After receiving acknowledgement that the third SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
14. The READY timer expires in the SwMI SNDCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDCP receives SN-END OF DATA PDU, stops its READY timer and any CONTEXT\_READY timers, starts the STANDBY timer and enters STANDBY state on the indicated channel.

NOTE 1: If the existing advanced links do not include the advanced link which the MS has assigned to this PDP context, the MS may setup the assigned advanced link following receipt of the SN-DATA TRANSMIT REQUEST PDU from the SwMI. The SwMI may then switch to using this new advanced link if it thinks this is the most suitable for carrying data for this PDP context.

A scenario illustrating acknowledged data sending from the SwMI to MS over an advanced link having TL-SDU window size of 3 is shown in figure 28.32. Each numbered step is explained in the following list.

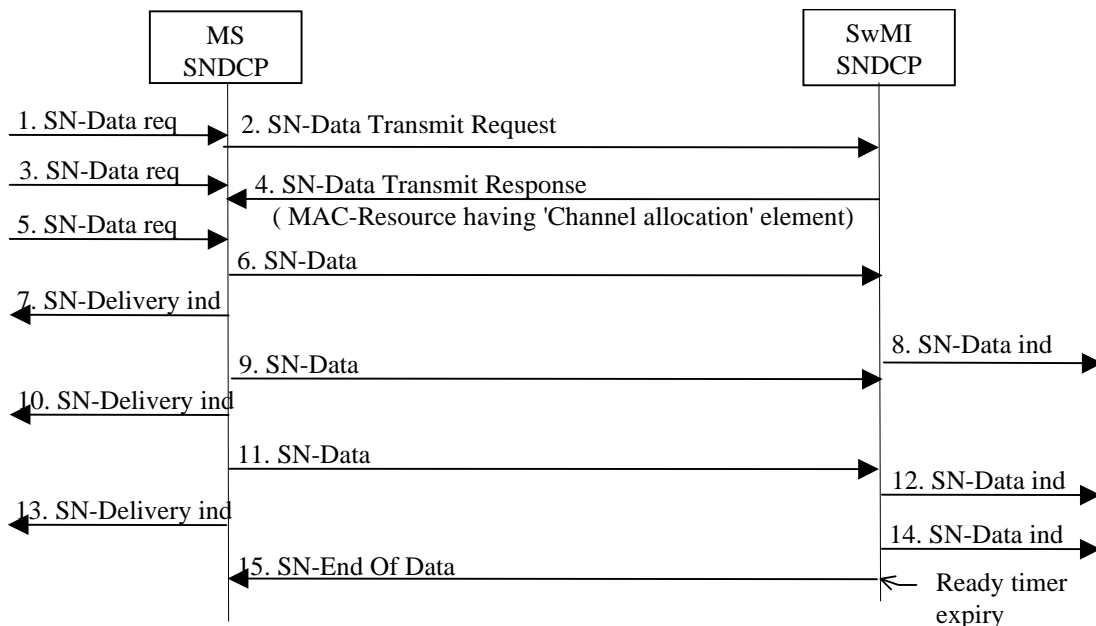

**Figure 28.32: Acknowledged service on advanced link having TL-SDU window size 3, data from SwMI to MS**

1. The SwMI SND'CP receives the first SN-DATA request primitive.
2. The SwMI SND'CP sends SN-DATA TRANSMIT REQUEST PDU. The request is sent by using the acknowledged or unacknowledged service (basic link) and the MAC-RESOURCE PDU contains a "Channel Allocation" information element sending the MS to a PDCH (the method of choosing the PDCH is given in clause 28.3.4.8). On transmission of the SN-DATA TRANSMIT REQUEST PDU, the SwMI stops the STANDBY timer, starts the READY timer and enters state READY. On reception of the SN-DATA TRANSMIT REQUEST PDU, the MS stops the STANDBY timer, starts the READY timer, starts the CONTEXT\_READY timer for the PDP context referenced by the NSAPI parameter in the SN-DATA request primitive, and enters state READY.
3. The SwMI SND'CP receives the second SN-DATA request primitive.
4. The first N-PDU is sent to the MS by issuing SN-DATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN-DATA PDU was successfully transmitted by the lower layers, the SwMI SND'CP entity shall restart the READY timer. At the MS the reception of the SN-DATA PDU shall result in the READY timer and, if supported, the CONTEXT\_READY timer being restarted.
5. The second N-PDU is sent (immediately after the first one) to the MS by issuing SN-DATA PDU as the sliding TL-SDU window allows it.
6. The SwMI SND'CP receives the third SN-DATA request primitive.
7. The third N-PDU is sent to the MS by issuing SN-DATA PDU as the sliding TL-SDU window allows it.

8. The SwMI SNDCP receives the fourth SN-DATA request primitive. The N-PDU cannot be sent to the MS yet as the sliding window is full.
9. The SwMI SNDCP receives the fifth SN-DATA request primitive. The N-PDU cannot be sent to the MS yet as the sliding window is full.
10. After receiving the first SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
11. After receiving acknowledgement that the first SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
12. The fourth N-PDU is sent to the MS by issuing SN-DATA PDU as the TL-SDU window now allows it (since the first N-PDU was transmitted correctly and thus the sliding TL-SDU window may advance).
13. After receiving the second SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
14. After receiving acknowledgement that the second SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
15. The fifth N-PDU is sent to the MS by issuing SN-DATA PDU as the TL-SDU window now allows it (since the second N-PDU was transmitted correctly and thus the sliding TL-SDU window may advance).
16. After receiving the third SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
17. After receiving acknowledgement that the third SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer. If the SNDCP had more N-PDUs for the MS one PDU could be sent now since the sliding window would allow it. However, in this example there is no more data to send.
18. After receiving the fourth SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
19. After receiving acknowledgement that the fourth SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
20. After receiving the fifth SN-DATA PDU the MS SNDCP passes the N-PDU to the higher layer by issuing a SN-DATA indication primitive.
21. After receiving acknowledgement that the fifth SN-DATA PDU was successfully sent to the MS the SwMI sends SN-DELIVERY indication primitive to the higher layer.
22. The READY timer expires in the SwMI SNDCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDCP receives SN-END OF DATA PDU, stops its READY timer, starts the STANDBY timer and enters STANDBY state on the indicated channel.

A scenario illustrating acknowledged data sending from MS to SwMI is shown in figure 28.33. Each numbered step is explained in the following list.

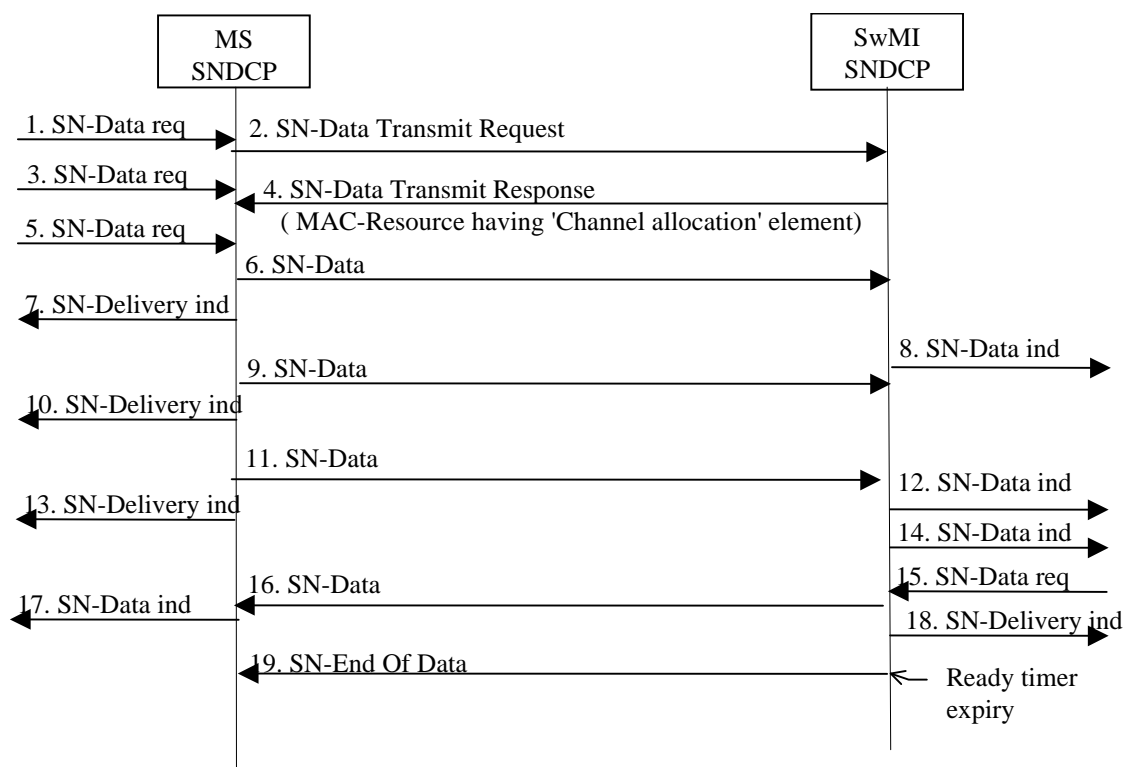

**Figure 28.33: Acknowledged service, data from MS to SwMI**

1. The MS SNDCP receives the first SN-DATA request primitive.
2. The MS SNDCP sends SN-DATA TRANSMIT REQUEST PDU. The request is sent by using acknowledged service (basic link). On sending the SN-DATA TRANSMIT REQUEST PDU, the MS SNDCP entity, starts the RESPONSE\_WAIT timer and enters RESPONSE-WAITING state.
3. The MS SNDCP receives the second SN-DATA request primitive.
4. The SwMI SNDCP sends SN-DATA TRANSMIT RESPONSE PDU. The response is sent by using the acknowledged or unacknowledged service (basic link) and the MAC-level MAC-RESOURCE PDU contains channel allocation information element commanding the MS to PDCH. On transmission of the SN-DATA TRANSMIT RESPONSE PDU, the SwMI stops the STANDBY timer, starts the READY timer, may start a CONTEXT\_READY timer (see clause 28.2.6.2) and enters state READY. On reception of the SN-DATA TRANSMIT RESPONSE PDU, the MS stops the STANDBY and RESPONSE\_WAIT timers, starts the READY timer and the relevant CONTEXT\_READY timer, and enters state READY.
5. The MS SNDCP receives the third SN-DATA request primitive.
6. The first N-PDU is sent to the SwMI by issuing SN-DATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN\_DATA PDU was successfully transmitted by the lower layers, the MS SNDCP entity shall restart the READY timer and shall, if supported, restart the relevant CONTEXT\_READY timer. At the SwMI the reception of the SN-DATA PDU shall result in the READY timer being restarted and, if used, the CONTEXT\_READY timer is restarted.
7. After receiving acknowledgement that the first SN-DATA PDU was successfully sent to the SwMI, the MS sends SN-DELIVERY indication primitive to the higher layer.
8. After receiving the first SN-DATA PDU, the SwMI SNDCP passes the N-PDU to the higher layer by issuing SN-DATA indication primitive.

9. The second N-PDU is sent to the SwMI by issuing SN-DATA PDU. The READY timer is restarted in the MS SNDPCP and in the SwMI SNDPCP. The relevant CONTEXT\_READY timer is restarted in the MS SNDPCP and, if used, in the SwMI SNDPCP. If scheduled access was agreed with the SwMI for this PDP context during PDP context activation, the MS SNDPCP indicates that the SN-PDU is scheduled and includes the value of the maximum schedule period for this PDP context in the MLE-UNITDATA request primitives carrying this and all subsequent SN-DATA PDUs for this PDP context.
10. After receiving acknowledgement that the second SN-DATA PDU was successfully sent to the SwMI, the MS sends SN-DELIVERY indication primitive to the higher layer.
11. The third N-PDU is sent to the SwMI by issuing SN-DATA PDU. The READY timer is re-started in the MS SNDPCP and in the SwMI SNDPCP. The relevant CONTEXT\_READY timer is restarted in the MS SNDPCP and, if used, in the SwMI SNDPCP.
12. After receiving the second SN-DATA PDU, the SwMI SNDPCP passes the N-PDU to the higher layer by issuing SN-DATA indication primitive.
13. After receiving acknowledgement that the third SN-DATA PDU was successfully sent to the SwMI, the MS sends SN-DELIVERY indication primitive to the higher layer.
14. After receiving the third SN-DATA PDU the SwMI SNDPCP passes the N-PDU to the higher layer by issuing SN-DATA indication primitive.
15. The READY timer expires in the SwMI SNDPCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDPCP receives SN-END OF DATA PDU, stops its READY timer and any CONTEXT\_READY timers, starts the STANDBY timer and enters STANDBY state in the allocated channel.

A scenario illustrating acknowledged data sending from MS to SwMI and from SwMI to MS is shown in figure 28.34. Each numbered step is explained in the following list.

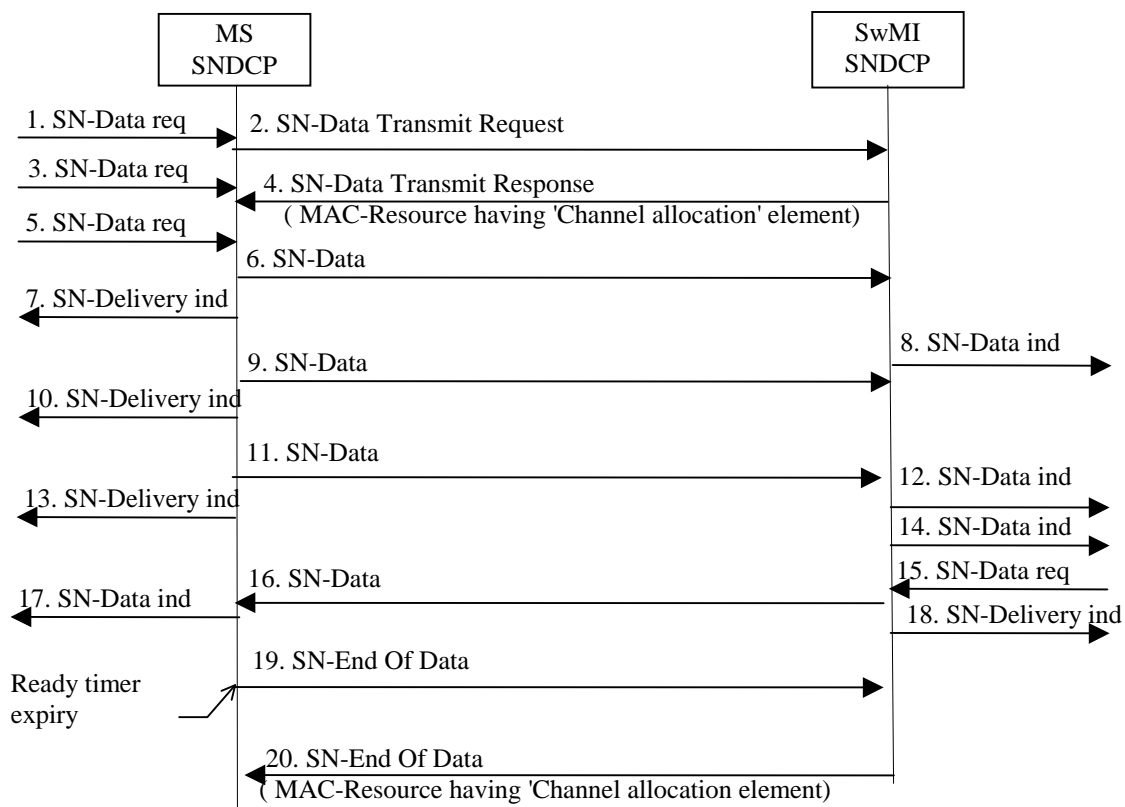

**Figure 28.34: Acknowledged service, data from MS to SwMI and from SwMI to MS**

1. to 14. These steps as in figure 28.33 "acknowledged service, data from MS to SwMI".
15. The SwMI SNDPCP receives the first (and only one in this scenario) SN-DATA request primitive.

16. The first N-PDU is sent to the MS by issuing SN-DATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN\_DATA PDU was successfully transmitted by the lower layers, the SwMI SNDSCP entity shall restart the READY timer and, if used, the CONTEXT\_READY timer. At the MS, the reception of the SN-DATA PDU shall result in the READY timer being restarted. The MS SNDSCP also starts the CONTEXT\_READY timer referenced by the NSAPI in the SN-DATA PDU.
17. After receiving the first SN-DATA PDU, the MS SNDSCP passes the N-PDU to the higher layer by issuing SN-DATA indication primitive.
18. After receiving acknowledgement that the first SN-DATA PDU was successfully sent to the MS, the SwMI sends SN-DELIVERY indication primitive to the higher layer.
19. The READY timer expires in the SwMI SNDSCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDSCP receives SN-END OF DATA PDU, stops its READY timer, stops all CONTEXT\_READY timers, starts the STANDBY timer and enters STANDBY state on the allocated channel.

A scenario illustrating Ready timer expiry in the MS is shown in figure 28.35. Each numbered step is explained in the following list.

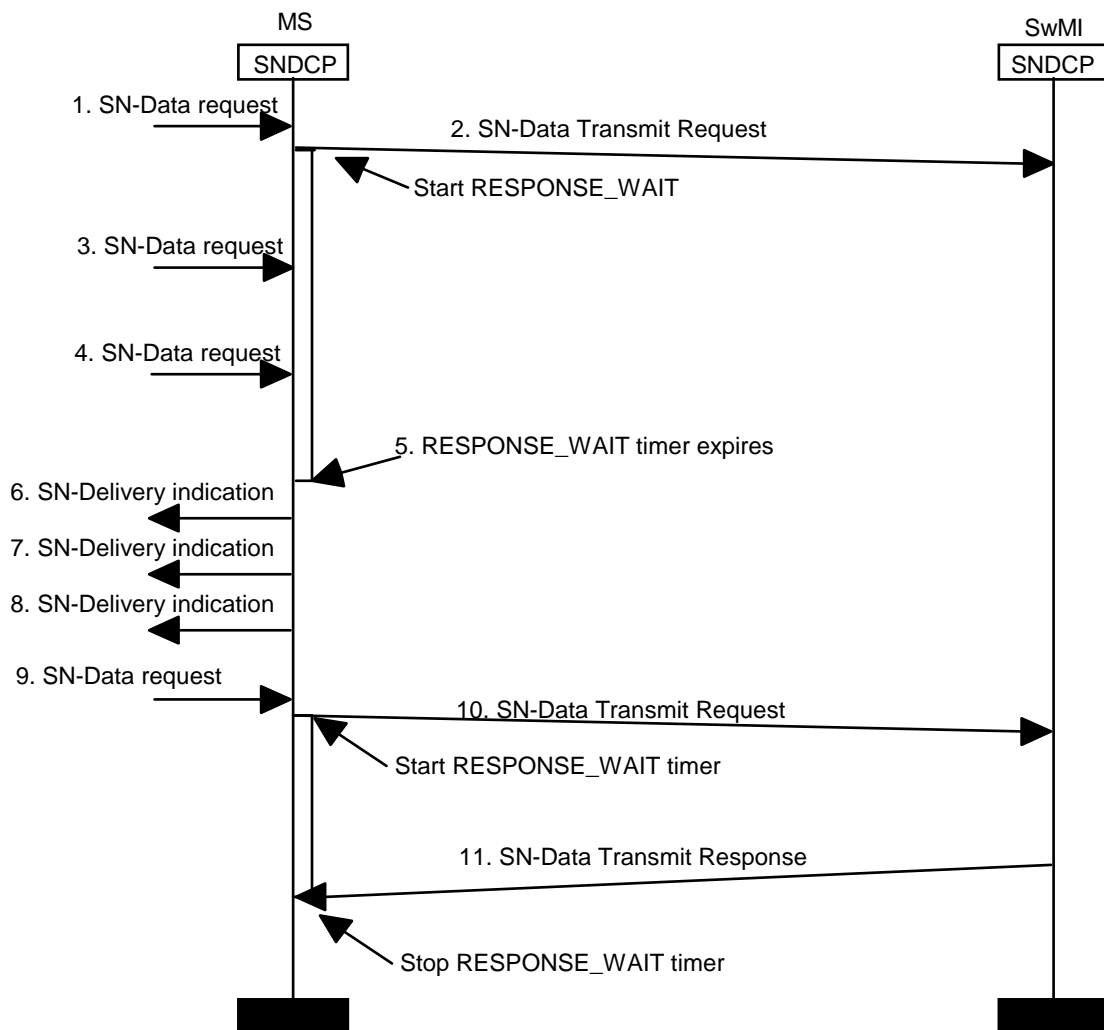

**Figure 28.35: Acknowledged service, READY timer expiry in the MS**

1. to 14. These steps are the same as in figure 28.33 "acknowledged service, data from MS to SwMI".
15. The SwMI SNDSCP receives the first (and only one in this scenario) SN-DATA request primitive.
16. The first N-PDU is sent to the MS by issuing SN-DATA PDU. The READY timer and, if used, the CONTEXT\_READY timer are started in the SwMI SNDSCP (when the SN-DATA PDU is successfully sent) and in the MS SNDSCP (when the SN-DATA PDU is received). The relevant CONTEXT\_READY timer is also started in the MS SNDSCP when the SN-DATA PDU is received.
17. After receiving the first SN-DATA PDU the MS SNDSCP passes N-PDU to the higher layer by issuing SN-DATA indication primitive.

18. After receiving acknowledgement that the first SN-DATA PDU was successfully sent to the MS the SwMI sends SN-Delivery indication primitive to the higher layer.
19. The READY timer expires in the MS SNDCP and it issues SN-END OF DATA PDU to the SwMI. The MS restarts the READY timer.
20. After receiving SN-END OF DATA PDU from the MS SNDCP the SwMI SNDCP issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDCP receives SN-END OF DATA PDU, stops its READY timer, starts the STANDBY timer and enters STANDBY state on the allocated channel.

A scenario illustrating RESPONSE\_WAIT timer expiry in the MS is shown in figure 28.36. Each numbered step is explained in the following list.

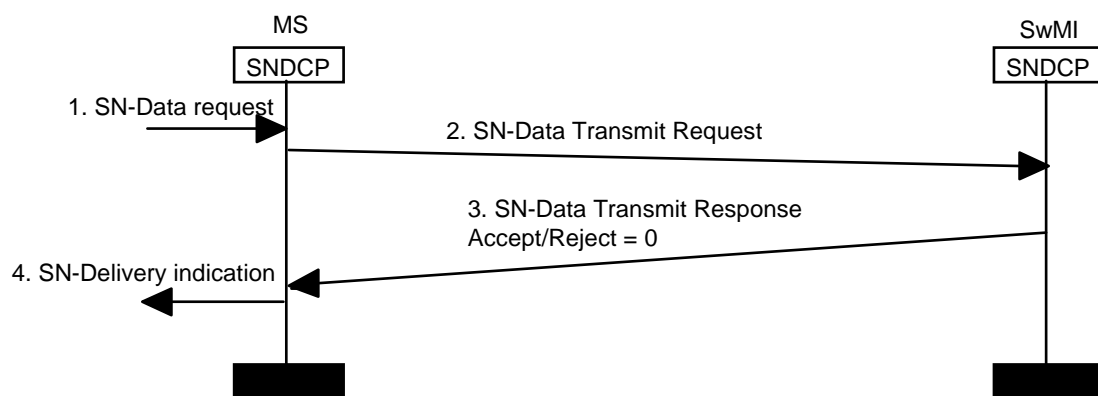

NOTE: The present document does not define the number of SN-DATA and SN-UNITDATA request primitives which may be buffered in the MS while the RESPONSE\_WAIT timer is active.

**Figure 28.36: Acknowledged service, RESPONSE\_WAIT timer expiry in the MS**

1. The service user issues a SN-DATA request primitive to the MS SNDCP entity.
2. The MS SNDCP entity transmits a SN-DATA TRANSMIT REQUEST PDU, starts the RESPONSE\_WAIT timer and enters RESPONSE-WAITING state.
3. The service user issues a second SN-DATA request primitive to the MS SNDCP entity.
4. The service user issues a third SN-DATA request primitive to the MS SNDCP entity.

5. The RESPONSE\_WAIT timer expires. The MS SNDCP entity enters STANDBY state.
6. The MS SNDCP entity issues a SN-DELIVERY indication primitive to the service user, giving notification that the SN-DATA request primitive received in 1) has failed.
7. The MS SNDCP entity issues a SN-DELIVERY indication primitive to the service user, giving notification that the SN-DATA request primitive received in 3) has failed.
8. The MS SNDCP entity issues a SN-DELIVERY indication primitive to the service user, giving notification that the SN-DATA request primitive received in 4) has failed.
9. The service user issues a new SN-DATA request primitive to the MS SNDCP entity.
10. The MS SNDCP entity transmits a SN-DATA TRANSMIT REQUEST PDU, starts the RESPONSE\_WAIT timer and enters RESPONSE-WAITING state.
11. The MS SNDCP entity receives a SN-DATA TRANSMIT RESPONSE PDU (with Accept/Reject = 1). The RESPONSE\_WAIT and STANDBY timers are stopped and the READY state is entered. The MS may now send the N-PDUs received from the service user, using SN-DATA PDUs as described in the previous examples.

A scenario illustrating SwMI rejecting a request from the MS is shown in figure 28.37. Each numbered step is explained in the following list.

**Figure 28.37: Acknowledged service, SwMI rejects request**

1. The service user issues a SN-DATA request primitive to the MS SNDCP entity.
2. The MS SNDCP entity transmits a SN-DATA TRANSMIT REQUEST PDU, starts the RESPONSE\_WAIT timer and enters RESPONSE-WAITING state.
3. Due to heavy system loading the SwMI rejects the request. The SwMI delivers a SN-DATA TRANSMIT RESPONSE PDU to the MS, with Accept/Reject set to "Request rejected by the SwMI", and "Transmit Response Reject Cause" set to "System resources not available". The MS stops its RESPONSE\_WAIT timer, restarts the STANDBY timer and enters STANDBY state.
4. The MS SNDCP entity issues a SN-DELIVERY indication primitive to the service user, giving notification that the SN-DATA request primitive received in 1) has failed.

NOTE 2: For direct access, the BS always supports the SNDCP service while the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDU is indicating "normal mode" (system wide services supported); see clause 18. The MS SNDCP may send the SwMI an SN-DATA TRANSMIT REQUEST PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported"; however the BS in this mode may temporarily not support the SNDCP service, in which case the BS may send the SN-DATA TRANSMIT RESPONSE PDU with reject cause "SNDCP service temporarily not available". If the MS receives an SN-DATA TRANSMIT RESPONSE PDU with reject cause "SNDCP service temporarily not available", the MS should not continue to send the SN-DATA TRANSMIT REQUEST PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDU is indicating "system wide services temporarily not supported" (though the MS is not precluded from occasionally sending the SN-DATA TRANSMIT REQUEST PDU).

A conventional access MS is not permitted to send SN-DATA TRANSMIT REQUEST or SN-DATA PDUs while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDCP service is not available on this cell".

NOTE 3: The MS is not permitted to send SN-DATA TRANSMIT REQUEST or SN-DATA PDUs on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

### 28.3.5.2 Unacknowledged data service (advanced link)

The SwMI may use also unacknowledged service (advanced link) to send N-PDUs. The procedures for unacknowledged data transfer differ from those of acknowledged data transfer when the destination is a group address. The READY timer is not activated when an MS enters READY state for reception of point to multipoint packet data. Also the reception of a point to multipoint N-PDU does not effect any of the SNDCP timers.

A scenario illustrating unacknowledged data sending from SwMI to MS using an advanced link is shown in figure 28.38. Each numbered step is explained in the following list.

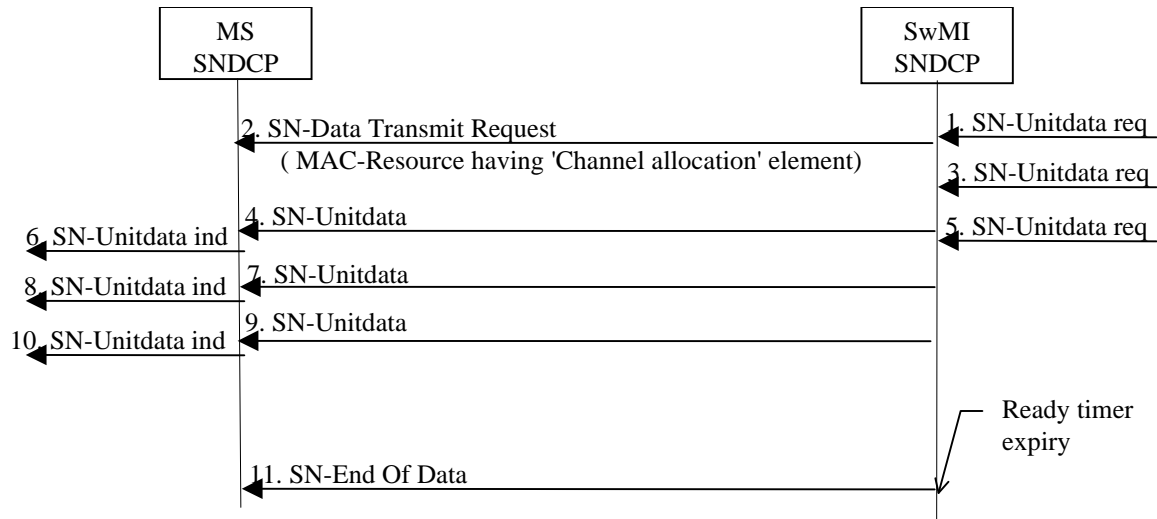

Figure 28.38: Unacknowledged service, data from SwMI to MS

1. The SwMI SNDCP receives the first SN-UNITDATA request primitive.
2. The SwMI SNDCP sends SN-DATA TRANSMIT REQUEST PDU. The request is sent by using unacknowledged service (basic link) and the MAC-RESOURCE PDU contains channel allocation information element commanding the MS to PDCH. The STANDBY timer is stopped and the READY timer is started in the SwMI SNDCP (when the SN-DATA TRANSMIT REQUEST PDU is sent). The STANDBY timer is stopped in the MS SNDCP (when the SN-DATA TRANSMIT REQUEST PDU is received).
3. The SwMI SNDCP receives the second SN-UNITDATA request primitive.

4. The first N-PDU is sent to the MS by issuing SN-UNITDATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN-UNITDATA PDU was transmitted by the lower layers, the SwMI SNDCP entity shall restart the READY timer.
5. The SwMI SNDCP receives the third SN-UNITDATA request primitive.
6. After receiving the first SN-UNITDATA PDU, the MS SNDCP passes the N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
7. The second N-PDU is sent to the MS by issuing SN-UNITDATA PDU. The READY timer is re-started in the SwMI SNDCP.
8. After receiving the second SN-UNITDATA PDU, the MS SNDCP passes the N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
9. The third N-PDU is sent to the MS by issuing SN-UNITDATA PDU. The READY timer is re-started in the SwMI SNDCP.
10. After receiving the third SN-UNITDATA PDU, the MS SNDCP passes N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
11. The READY timer expires in the SwMI SNDCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDCP receives SN-END OF DATA PDU, starts the STANDBY timer and enters STANDBY state on the allocated channel.

### 28.3.5.2a Usage of Resource request

See also clause 28.3.4.8 on selection of physical channels and clause 28.3.4.2 on logical link setup.

The MS SNDCP entity should normally set "enhanced  $\pi/4$ -DQPSK service" information element to indicate "enhanced  $\pi/4$ -DQPSK service not requested" when transmitting an SN-DATA TRANSMIT REQUEST PDU, SN-PAGE RESPONSE or SN-RECONNECT PDU. The MS should not include the conditional "resource request" information element unless the MS advised the SwMI during registration that it supports QAM modulation but now specifically requires a phase modulation PDCH or unless the MS wishes to request a specific number of phase modulation timeslots per TDMA frame.

By default, if the MS did not negotiate QoS for a particular PDP context and the MS does not include a "resource request" information element in the SN-DATA TRANSMIT REQUEST PDU, SN-PAGE RESPONSE or SN-RECONNECT PDU, the SwMI chooses the connection based on the MS's declared capabilities and the default assumption that the MS requires a background class QoS with unspecified throughput, delay and reliability.

NOTE 1: In version 3.4.1 (and in earlier versions) [i.16] of the present document, an MS that did not negotiate QoS was assigned to a single-slot  $\pi/4$ -DQPSK PDCH if it did not include a "resource request" information element.

The MS SNDCP entity may request a phase modulation single or multi-slot service (within its declared capabilities) in PDCH access signalling. That may be indicated by setting the "enhanced  $\pi/4$ -DQPSK service" information element to "enhanced  $\pi/4$ -DQPSK service requested" in the SN-DATA TRANSMIT REQUEST (data from MS to SwMI), SN-PAGE RESPONSE (data from MS to SwMI) or SN-RECONNECT PDU transmitted to the peer entity. If enhanced  $\pi/4$ -DQPSK service is indicated in the PDU, the PDU shall also contain a conditional "resource request" information element, which shall either inform the SwMI of the desired number of timeslots per TDMA frame in the PDCH or shall inform the SwMI that an unspecified phase modulation resource is required. If a specific phase modulation resource is required, the required number of phase modulation timeslots per TDMA frame shall be informed to the SwMI before the MS has already been directed to a PDCH. In consequence this shall aid the SwMI in directing the MSs to the proper channels, and access to resources, where the actual data transfer occurs, is immediate.

EXAMPLE: A QAM-capable MS sending or receiving limited quantities of data over an extended period of time may prefer to use any available phase modulation PDCH for reasons of battery economy.

If no advanced link exists, the MS establishes an advanced link when it arrives on the PDCH.

If the MS requires a single or multi-slot phase modulation connection and the "resource request" information element is not used, the MS may be directed to a QAM channel (if it supports QAM), or may be directed to a phase modulation channel (within its declared capabilities) with the wrong number of timeslots per TDMA frame to do the advanced link set up. If the MS was directed to the wrong type of channel, advanced link negotiation may cause the SwMI to direct the MS to the actual single or multi-slot phase modulation channel to do the data transfer. In this case the MS visits completely uselessly on the wrong type of channel for a short time. If the requirement for single or multi-slot phase modulation packet data is indicated earlier by using the "resource request" information element, the MS can be moved directly to the desired phase modulation channel, and latency time to the resource access can be reduced.

If the MS uses the "resource request" information element:

- If no advanced link exists when the MS has been sent to a PDCH and the MS used the "resource request" information element, the MS SNDCP entity shall use the data transfer throughput and number of  $\pi/4$ -DQPSK timeslots per TDMA frame parameters which were indicated in the "resource request" information element during the advanced link set up negotiation on the PDCH. This applies on all types of PDCH (i.e. not just on a phase modulation PDCH).
- If an advanced link has already been established for the packet data service when the MS enters from STANDBY state to READY state (i.e. MS has visited on the PDCH at least once before), the MS's AL-SETUP PDU that initiated the establishment of the advanced link did not indicate "no information about radio resources" and the MS requires a phase modulation PDCH, the MS shall adapt the requested width of the PDCH in PDCH access signalling with the already negotiated advanced link parameters.

When MSs requiring phase modulation PDCHs indicate their requested data transfer throughput values in the "resource request" information element before being directed to the PDCH, the BS may be able to optimize its resource allocations between several MSs on the same channel and direct them to the proper channels right away. The "connection symmetry" information element indicates whether the same number of timeslots per TDMA frame shall be used both on uplink and downlink. In the case of symmetric connection, the next information element, "number of  $\pi/4$ -DQPSK timeslots on uplink", shall indicate the number of requested timeslots both on uplink and downlink. In that case the "number of  $\pi/4$ -DQPSK timeslots on downlink" information element is not needed at all.

Instead if asymmetric connection is indicated by the "connection symmetry" information element, the information element "number of  $\pi/4$ -DQPSK timeslots on downlink" is also present. Then the number of  $\pi/4$ -DQPSK timeslots requested on uplink and downlink shall be indicated by different information elements.

NOTE 2: The actual protocol part of asymmetric connection is outside the scope of the present document, i.e. different timeslot requests on uplink and downlink are not used in the present version of this document.

The "full phase modulation capability" information element shall indicate the MS's capability to handle physical resources. Any resource granting over this capability limit by the SwMI is useless, because the MS does not have physical capabilities to handle more timeslots in one TDMA frame than indicated by this information element.

NOTE 3: How the SwMI should handle the situation where more resources have been negotiated than indicated by the capability limit is outside the scope of the present document.

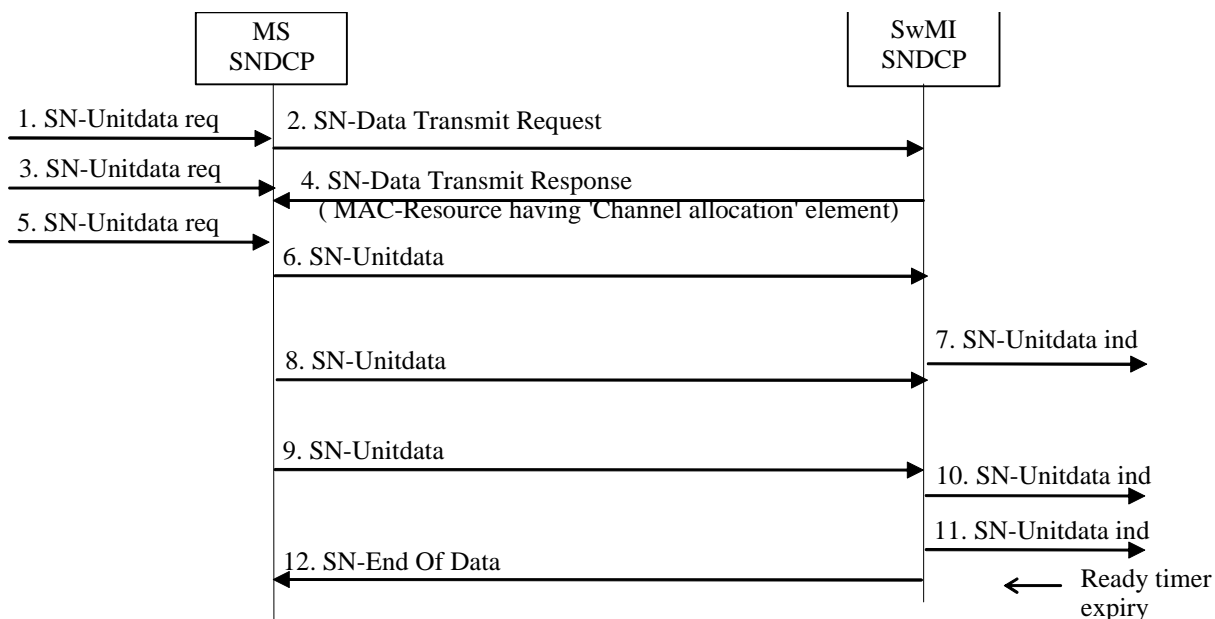

### 28.3.5.2b Unacknowledged data service (basic link)

The unacknowledged data service (basic link) shall be used by the MS to transmit data from a PDP context for which real-time class data was agreed during QoS negotiation. It may also be used by the SwMI.

When the MS SNDCP receives a SN-UNITDATA request primitive for a real-time class PDP context, it shall follow the normal rules for transmitting an SN-DATA TRANSMIT REQUEST PDU. When the MS receives a SN-DATA TRANSMIT REQUEST PDU or a SN-DATA TRANSMIT RESPONSE PDU for a real-time class PDP context, the MS shall follow any included channel allocation, and may then transmit any waiting SN-UNITDATA PDUs on the unacknowledged basic link immediately (the unacknowledged basic link does not need to be set up).

Each SN-UNITDATA PDU shall be passed to the MLE layer in a MLE-UNITDATA request primitive, accompanied by an indication that the unacknowledged basic link is to be used, and an indication of the number of retransmissions of the SN-UNITDATA PDU and an indication of whether an FCS is required. In the case of real-time class data, the number of retransmissions will normally be zero.

A scenario illustrating unacknowledged basic link data sending from MS to SwMI is shown in figure 28.39. Each numbered step is explained in the following list.

**Figure 28.39: Unacknowledged basic link service, data from MS to SwMI**

1. The MS SNDPCP receives the first SN-UNITDATA request primitive.
2. The MS SNDPCP sends SN-DATA TRANSMIT REQUEST PDU. The request is sent by using acknowledged service (basic link). On sending the SN-DATA TRANSMIT REQUEST PDU, the MS SNDPCP entity starts the RESPONSE\_WAIT timer and enters RESPONSE-WAITING state.
3. The MS SNDPCP receives the second SN-UNITDATA request primitive.
4. The SwMI SNDPCP sends SN-DATA TRANSMIT RESPONSE PDU. The response may be sent by using the acknowledged basic link service of the unacknowledged basic link service and the MAC-level MAC-RESOURCE PDU contains a channel allocation information element commanding the MS to a PDCH. On transmission of the SN-DATA TRANSMIT RESPONSE PDU, the SwMI stops the STANDBY timer, starts the READY timer, may start a CONTEXT\_READY timer (see clause 28.2.6.2) and enters state READY. On reception of the SN-DATA TRANSMIT RESPONSE PDU, the MS stops the STANDBY and RESPONSE\_WAIT timers, starts the READY timer and the relevant CONTEXT\_READY timer, and enters state READY.
5. The MS SNDPCP receives the third SN-UNITDATA request primitive.
6. The first N-PDU is sent to the SwMI by issuing an SN-UNITDATA PDU. On reception of an indication from the MLE, in the form of an MLE-REPORT indication primitive, that the SN-UNITDATA PDU was transmitted by the lower layers, the MS SNDPCP entity shall restart the READY timer and shall, if supported, restart the relevant CONTEXT\_READY timer. At the SwMI the reception of the SN-UNITDATA PDU shall result in the READY timer and, if used, the CONTEXT\_READY timer being restarted.
7. After receiving the first SN-UNITDATA PDU, the SwMI SNDPCP passes the N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
8. The second N-PDU is sent to the SwMI by issuing SN-UNITDATA PDU. If scheduled access was agreed with the SwMI for this PDP context during PDP context activation, the MS SNDPCP indicates that this SN-PDU is scheduled and indicates the value of the maximum schedule period for this PDP context in the MLE-UNITDATA request primitives carrying this and all subsequent SN-UNITDATA PDUs for this PDP context. The READY timer is re-started in the MS SNDPCP and in the SwMI SNDPCP. If supported, the relevant CONTEXT\_READY timer is restarted in the MS and SwMI SNDPCP.
9. The third N-PDU is sent to the SwMI by issuing SN-UNITDATA PDU. If scheduled access was agreed with the SwMI for this PDP context during PDP context activation, the MS SNDPCP indicates that this SN-PDU is scheduled. The READY timer is re-started in the MS SNDPCP. If supported, the relevant CONTEXT\_READY timer is restarted in the MS and SwMI SNDPCP.

10. After receiving the second SN-UNITDATA PDU, the SwMI SNDCP re-starts the READY timer and, if used, the CONTEXT\_READY timer and passes the N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
11. After receiving the third SN-UNITDATA PDU the SwMI SNDCP re-starts the READY timer and, if used, the CONTEXT\_READY timer and passes the N-PDU to the higher layer by issuing SN-UNITDATA indication primitive.
12. The READY timer expires in the SwMI SNDCP and it issues SN-END OF DATA PDU, including channel allocation, to the MS, starts the STANDBY timer and enters STANDBY state. The MS SNDCP receives SN-END OF DATA PDU, stops its READY timer and any CONTEXT\_READY timers, starts the STANDBY timer and enters STANDBY state in the allocated channel.

NOTE 1: For direct access, the BS always supports the SNDCP service while the "system wide services" information element in the D-MLE-SYSINFO-DA (and D-MLE-SYNC-DA) PDUs is indicating "normal mode" (system wide services supported); see clause 18. The MS SNDCP may send the SwMI an SN-DATA TRANSMIT REQUEST PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA (or D-MLE-SYNC-DA) PDUs is indicating "system wide services temporarily not supported"; however the BS in this mode may temporarily not support the SNDCP service, in which case the BS may send the SN-DATA TRANSMIT RESPONSE PDU with reject cause "SNDCP service temporarily not available". If the MS receives an SN-DATA TRANSMIT RESPONSE PDU with reject cause "SNDCP service temporarily not available", the MS should not continue to send the SN-DATA TRANSMIT PDU while the "system wide services" information element in the D-MLE-SYSINFO-DA or D-MLE-SYNC-DA PDUs is indicating "system wide services temporarily not supported" (though the MS is not precluded from occasionally sending the SN-ACTIVATE PDP CONTEXT DEMAND PDU).

A conventional access MS should not send SN-DATA TRANSMIT REQUEST or SN-UNITDATA PDUs while the D-MLE SYSINFO or D-MLE SYSINFO-Q PDUs are indicating "SNDCP service is not available on this cell".

NOTE 2: If the BS becomes unable to support the SNDCP service while a direct access MS is sending real time class data to the SwMI, the BS may send the MS an SN-END OF DATA PDU to stop the MS from sending further SN-UNITDATA PDUs.

NOTE 3: The MS is not permitted to send SN-DATA TRANSMIT REQUEST or SN-UNITDATA PDUs on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5).

### 28.3.5.3 Protocol header compression

#### 28.3.5.3.1 Header compression types

Header compression attempts to remove redundant protocol header information of transmitted PDUs between source and destination addresses. The used compression method is specific for each network layer protocol type. TCP/IP (IPv4) and IP (IPv4 and IPv6) header compression are introduced in the present document.

Multiple types of header compression are supported. Negotiation of supported algorithms is carried out between MS and SwMI in Activate PDP Context procedure, if necessary. The negotiation uses the PCOMP negotiation information element (8 bits bitmap) in SN-ACTIVATE PDP CONTEXT PDUs whereas the control of the compression process is done by using the PCOMP information element (4 bits) in SN-DATA and SN-UNITDATA PDUs.

If the receiving SNDCP entity does not recognize the value of the PCOMP information element included in the SN-DATA PDU or SN-UNITDATA PDU it shall discard the PDU.

### 28.3.5.3.2 TCP/IP header compression

IETF RFC 1144 [29] defines an encoding method and protocol for compressing the standard 40-octet TCP/IP (IPv4) protocol header down to 3 octets at minimum. The standard TCP/IP header comprises 20 octets of IP part and 20 octets of TCP part. The idea is to replace the IP header with a one octet connection number, and the TCP header with delta information (only differences are sent).

TCP/IP header compression modes that require a reliable link should not be used with the unacknowledged layer 2 service.

The protocol requires that the underlying service should be able to distinguish three types of IP frames. The frame type information is conveyed in the PCOMP field of the SND CP header.

When compression is used, a TCP/IP header is replaced with a compressed header of length varying from 3 to 16 octets. Octet one carries a change mask that identifies which of the consequent fields has changed per packet. A mask bit is set if the associated field is changed and present in the header. The corresponding bit is clear if there are no changes, and the delta field is absent. The unmodified TCP checksum field, however, is always included in the compressed header. The format of the header is shown in table 28.19.

**Table 28.19: Compressed header format**

| Bit     | 8                     | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
|---------|-----------------------|---|---|---|---|---|---|---|
| Octet 1 | 0                     | C | I | P | S | A | W | U |
| 2       | Connection number (C) |   |   |   |   |   |   |   |
| 3       | TCP checksum          |   |   |   |   |   |   |   |
| 4       |                       |   |   |   |   |   |   |   |
| ..      | Urgent pointer (U)    |   |   |   |   |   |   |   |
| ..      | delta (Window) (W)    |   |   |   |   |   |   |   |
|         | delta (Ack) (A)       |   |   |   |   |   |   |   |
|         | delta (Sequence) (S)  |   |   |   |   |   |   |   |
| N       | delta (IP ID) (I)     |   |   |   |   |   |   |   |

The connection information table in each connection entity shall be initialized upon occurrence of:

- initial LLC connection establishment/release; or
- at any time when the SND CP entity concludes that the peer entity has lost TCP/IP header compression synchronization.

NOTE: Where an MS moves to a new cell and establishes an advanced link, there should not be a need for the connection information table to be re-initialized.

In TETRA packet data, each SND CP entity maintains two connection state tables per PDP context, one for N-PDUs sent (compressor state table) and one for N-PDUs received (decompressor state table). Within each table there may be up to 256 state slots, thus allowing the compression of up to 256 simultaneous TCP connections per PDP context. The exact number of state slots supported by SND CP entities is negotiated at context activation. The MS shall specify in the SN-ACTIVATE PDP CONTEXT DEMAND PDU the number of state slots which it can support for this context. The SwMI shall respond in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU with either the same value or a lower value. The lower of the values specified in the SN-ACTIVATE PDP CONTEXT DEMAND PDU and SN-ACTIVATE PDP CONTEXT ACCEPT PDU shall be used by both SND CP entities. It is recommended at least 16 state slots are supported per PDP context. It is also recommended that implementations should avoid specifying one slot during PDP context activation if possible.

### 28.3.5.3.3 IP header compression

IETF RFC 2507 [35] and IETF RFC 2508 [36] define an encoding method and protocol for compressing multiple types of IPv4 or IPv6 protocol header(s). This includes UDP/IP headers, which can be compressed down to 3 octets at minimum. The idea is as for the TCP/IP header compression described in clause 28.3.5.3.2 to replace the IP header(s) with a one or two octet context number, and required delta information (only differences are sent).

The protocol requires that the underlying service should be able to distinguish nine types of IP frames. The frame type information is conveyed in the PCOMP field of the SND CP header.

In TETRA packet data, each SNDCP entity maintains two context state tables per PDP context, one for N-PDUs sent (compressor context state table) and one for N-PDUs received (decompressor context state table). Within each table there may be up to 256 + 65 536 context state slots, thus allowing the compression of up to 256 simultaneous TCP connections and 65 536 simultaneous non-TCP "contexts" per PDP context. The exact number of state slots supported by SNDCP entities is negotiated at PDP context activation. The MS shall specify in the SN-ACTIVATE PDP CONTEXT DEMAND PDU the number of state slots which it can support for this context. The SwMI shall respond in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU with either the same value or a lower value. The lower of the values specified in the SN-ACTIVATE PDP CONTEXT DEMAND PDU and SN-ACTIVATE PDP CONTEXT ACCEPT PDU shall be used by both SNDCP entities. It is recommended at least 16 state slots be supported per PDP context. It is also recommended that implementations should avoid specifying one slot during PDP context activation if possible.

The context information table in each entity shall be initialized upon occurrence of:

- initial LLC connection establishment/release; or
- at any time when the SNDCP entity concludes that the peer entity has lost IP header compression synchronization.

NOTE: Where an MS moves to a new cell and establishes an advanced link, there should not be a need for the context information table to be re-initialized.

IP header compression modes that require a reliable link should not be used with the unacknowledged layer 2 service.

### 28.3.5.4 Data compression

#### 28.3.5.4.0 General

Data compression in TETRA Packet data shall primarily be done according to the Recommendation ITU-T V.42bis [27]. It is also possible to use alternative compression methods, if required.

The supported alternative data compression methods introduced in the present document are:

- BSD Compression (IETF RFC 1977 [32]);
- Predictor Compression (IETF RFC 1978 [33]).

#### 28.3.5.4.1 Support of multiple compression types

Each SNDCP entity shall be equipped with the ability to handle several compression types. Then, the means have to be arranged between the peer SNDCP entities to negotiate and switch on the selected algorithm.

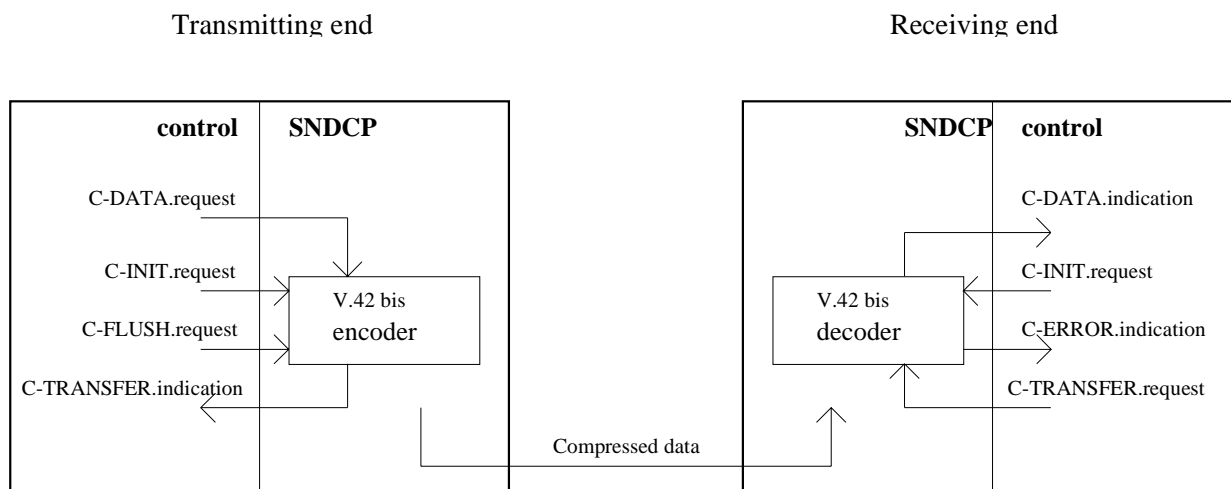

The negotiation of the supported algorithms needs to be done prior to data transfer, and it is done between the MS and SwMI in Activate PDP Context procedure. The MS sends a list of algorithms that it can support. The SwMI responds by picking up those algorithms on the list, which it accepts, and then returns a list of the permitted algorithms back to the MS. The format of the negotiation information element is similar for both directions.

Any permitted compression algorithm can be switched on during data transfer period. The selected compression type is identified with DCOMP parameter, which is carried in SN-DATA or SN-UNITDATA PDU frames.

If the receiving SNDCP entity does not recognize the value of the DCOMP information element included in the SN-DATA PDU or SN-UNITDATA PDU it shall discard the PDU.

### 28.3.5.4.2 Management of V.42bis data compression

According to the present document the use of data compression function and associated parameters shall be negotiated at initial connection establishment. The negotiated parameters, P0, P1 and P2 shall be transferred between MS and SwMI.

**Figure 28.40: Recommendation ITU-T V.42bis [27] data compression function**

The service interface of the Recommendation ITU-T V.42bis [27] data compression function is modelled as a set of abstract service primitives, figure 28.40. The control function at each end of data transfer shall issue a C-INIT request primitive to the data compression function after a successful negotiation of compression parameters and after completion of LLC link establishment.

To encode data, the SND CP control function shall issue a C-DATA request primitive to the data compression function, indicating the data to be encoded. The encoder indicates with C-TRANSFER indication primitive that the compressed data is ready to be delivered.

At the receiver end the encoded data block is delivered to the decoder unit using C-TRANSFER request primitive. After this the decoder indicates by C-DATA indication primitive that the decoded data block is ready to be moved further.

The C-FLUSH request primitive shall be used to preserve boundaries between network protocol data blocks (PDUs). The control function shall issue a C-FLUSH request primitive immediately after encoding of each PDU.

The C-ERROR indication primitive informs the control function that an error has been detected by the decoder. The error situation is recovered by re-establishing the LLC connection.

Any subsequent PDP context activation, which requests, and is granted, Recommendation ITU-T V.42bis [27] compression support with different Recommendation ITU-T V.42bis [27] compression parameters, shall cause the Recommendation ITU-T V.42bis [27] compression dictionaries to be cleared.

### 28.3.5.4.3 Management of BSD data compression

The BSD data compression algorithm is described in IETF RFC 1977 [32]. IETF RFC 1977 [32] describes the compression algorithm and defines the encapsulation header. The encapsulation is shown in table 28.20.

**Table 28.20: BSD compressed data format**

| Bit     | 8                    | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
|---------|----------------------|---|---|---|---|---|---|---|
| Octet 1 | Sequence             |   |   |   |   |   |   |   |
| 2       | Sequence (continued) |   |   |   |   |   |   |   |
| 3       | Compressed data      |   |   |   |   |   |   |   |
| etc.    | etc.                 |   |   |   |   |   |   |   |
| N       | Compressed data      |   |   |   |   |   |   |   |

The compressed data information element is the output of the BSD algorithm when applied to the original N-PDU content.

In TETRA packet data, each SNDPCP entity maintains two BSD compression dictionaries, one for N-PDUs sent (compressor dictionary) and one for N-PDUs received (decompressor dictionary). All BSD dictionaries shall be cleared at context activation.

If the decoder has detected an error, the error situation is recovered by re-establishing the LLC connection. According to the specification, the use of the BSD data compression function and associated parameters shall be negotiated at initial connection establishment. The negotiated parameters, version and dictionary size shall be transferred between MS and SwMI.

Any subsequent PDP context activation, which requests, and is granted, BSD compression support with different BSD compression parameters shall cause the BSD compression dictionaries to be cleared.

#### 28.3.5.4.4 Management of Predictor data compression

The predictor data compression algorithm is described in IETF RFC 1978 [33]. IETF RFC 1978 [33] describes the compression algorithm and defines two types of encapsulation headers. However, only type 1 encapsulation is allowed within the present document. The encapsulation is shown in table 28.21.

**Table 28.21: Predictor compressed data format**

| Bit     | 8                               | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
|---------|---------------------------------|---|---|---|---|---|---|---|
| Octet 1 | Uncompressed length (octets)    |   |   |   |   |   |   |   |
| Octet 2 | Uncompressed length (continued) |   |   |   |   |   |   |   |
| Octet 3 | Compressed data                 |   |   |   |   |   |   |   |
| etc.    | etc.                            |   |   |   |   |   |   |   |
| etc.    | etc.                            |   |   |   |   |   |   |   |
| Octet N | Compressed data                 |   |   |   |   |   |   |   |

The compressed data information element is the output of the predictor algorithm when applied to the original N-PDU content with an appended 16 bit CRC. This CRC shall be calculated as defined in IETF RFC 1662 [31].

In TETRA Packet data, each SNDPCP entity maintains two predictor compression dictionaries, one for N-PDUs sent (compressor dictionary) and one for N-PDUs received (decompressor dictionary). All predictor dictionaries shall be cleared at context activation. If the decoder has detected an error, the error situation is recovered by re-establishing the LLC connection.

According to the specification, the use of the predictor data compression function shall be negotiated at initial connection establishment. There are no negotiated parameters for the predictor data compression.

#### 28.3.5.5 Data Priority

##### 28.3.5.5.1 General

Except where stated otherwise, this clause shall be applicable only to MSs and SwMIs which support data priority.

SNDPCP may provide support for data priority. Eight levels of data priority are available. Data priority allows an MS to transmit high data-priority N-PDUs ahead of lower data-priority N-PDUs from the same MS and other MSs.

The SwMI indicates support for data priority in the "Extended services broadcast" information element of the MAC SYSINFO PDU. The MS SNDPCP is informed of this by the broadcast parameters in the MLE-INFO indication primitive.

The data priority of N-PDUs may be defined by the SNDPCP service user by two different methods. The first provides a data priority for each PDP context and the second allows the SNDPCP service user to set a data priority for individual N-PDUs.

The MS has three different methods for requesting data priority from the SwMI. The first method is conducted within SNDCP, and is a method of requesting a change to the data priority which the SwMI applies by default to all SN-DATA and SN-UNITDATA PDUs transmitted by the MS. The second method is applied at layer 2 in response to information from the MS SNDCP, and is a method of requesting short-term variations to the default data priority. This allows the SwMI to respond quickly to a priority increase while minimizing the amount of signalling required to track rapidly changing data priorities. The third method is applied by the MLE in response to information from the MS SNDCP and is a method of indicating that the MS needs high priority access to a PDCH so that it can be sent to the PDCH ahead of other waiting MSs with lower data priority.

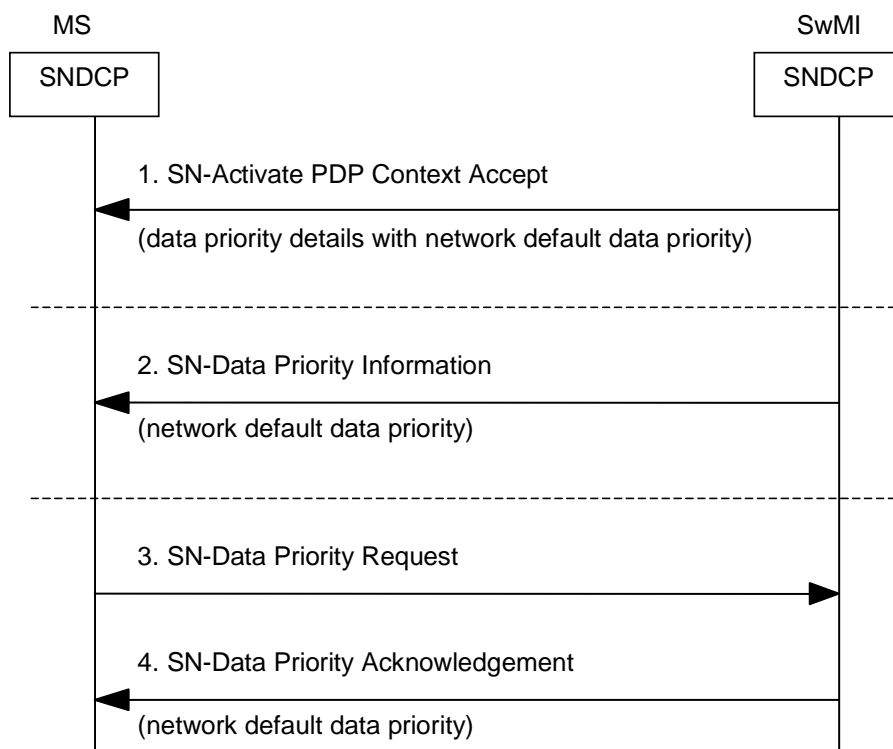

N-PDUs from an MS which does not support data priority will experience the network default data priority. When an MS supporting data priority uses a SwMI which does not support data priority, its N-PDUs and PDCH access requests are given the same data priority as all other MSs' requests.

**NOTE:** Data priority is distinct from PDU priority (see clause 28.6). PDU priority affects LLC queue reordering and the MS's permission to use random access opportunities. Data priority affects LLC queue reordering, slot granting delays and the speed of the MS's access to the PDCH.

### 28.3.5.5.2 Network default data priority and initial MS default data priority

Unless otherwise stated, this clause shall be applicable only to MSs and SwMIs that support data priority.

The SwMI should set a "network default data priority". It should apply the network default data priority to reservation requirements from MSs that do not support data priority or have not requested a change in "MS default data priority". An MS may discover the value of the network default data priority in the following ways described in figure 28.41.

**Figure 28.41: Method by which the MS SNDCP discovers the network default priority**

1. A SwMI that supports data priority should send MSs the value of the network default data priority in the "data priority details" information element in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU.
2. The SwMI may inform all MSs of the network default data priority by transmitting broadcast-addressed SN-DATA-PRIORITY INFORMATION PDUs from time to time. If the SwMI changes the network default data priority it should inform all MSs of the new network default data priority by transmitting broadcast-addressed SN-DATA-PRIORITY INFORMATION PDUs.

3. An MS SNDCP that has activated packet data context and received MLE INFO indication primitive advising that data priority is supported on the current cell may request the value of the network default data priority by sending an SN-DATA-PRIORITY REQUEST PDU to the SwMI.
4. The SwMI shall then notify the MS of the value of the network default data priority in an SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU.

The SwMI should set and record an initial "MS default data priority" when an MS activates a first PDP context. (This includes MSs which do not support data priority.) The SwMI should set the initial value of "MS default data priority" to the value of the "network default data priority".

When an MS is powered-up, and when it deactivates its last PDP context, the MS SNDCP shall set its recorded value of "MS default data priority" to "undefined" and shall inform MLE that the MS default data priority is "not applicable" using the MLE-CONFIGURE request primitive.

When the MS SNDCP receives a value of network default data priority, then:

- if MS default data priority is "undefined", the MS SNDCP shall set MS default data priority to the value of network default data priority. If in the READY state and the MS wishes to use data priority, MS SNDCP shall then inform MLE of the MS default data priority using the MLE-CONFIGURE request primitive; or
- if MS default data priority has been set from a previous value of network default data priority, the MS SNDCP shall set MS default data priority to the new value of network default data priority. If in the READY state and the MS wishes to use data priority, the MS SNDCP shall then inform MLE of the new MS default data priority using the MLE-CONFIGURE request primitive; or
- if MS default data priority has been set by negotiation with the SwMI, the MS SNDCP shall not set MS default data priority to the value of network default data priority.

If the MS SNDCP wishes to revert a negotiated MS data priority back to the network default data priority, so that it tracks future values of the network default data priority, the MS SNDCP should send the SwMI a SN-DATA-PRIORITY REQUEST PDU with the "data priority request type" set to "set MS default data priority to track network default data priority". If the resulting SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU from the SwMI indicates that MS default data priority has been set to the network default data priority, the MS SNDCP shall set its local value of MS default data priority to the value of network default data priority included in the same PDU. If in the READY state, the MS SNDCP shall then inform MLE of the new MS default data priority using the MLE-CONFIGURE request primitive.

Similarly, if the MS SNDCP receives an SN-DATA-PRIORITY INFORMATION PDU from the SwMI indicating that MS default data priority has been set to the network default data priority, the MS SNDCP shall set its local value of MS default data priority to the value of network default data priority included in the same PDU. If in the READY state, the MS SNDCP shall then inform MLE of the new MS default data priority using the MLE-CONFIGURE request primitive.

When the MS SNDCP enters the READY state and wishes to use data priority and the MS default data priority has a defined value (i.e. not equal to "undefined"), it should send the value of the MS default data priority to MLE in the MS default data priority parameter of the MLE-CONFIGURE request primitive. When the MS SNDCP leaves the READY state, it shall inform MLE that the MS default data priority is "not applicable".

### 28.3.5.5.3 NSAPI data priority

This clause shall be applicable only to MSs which support data priority.

When an SNDCP service user requests activation of a PDP context (using the SN-NSAPI ALLOC request primitive), the SNDCP service user may include a default data priority for N-PDUs using that PDP context in the "NSAPI data priority" parameter. The MS SNDCP shall record a value for this parameter for each activated PDP context. It shall record the value "undefined" for any PDP context where an NSAPI data priority parameter was not provided.

The SNDCP service user may ask the MS SNDCP to modify the NSAPI data priority of a particular PDP context at any time by use of the SN-NSAPI CONFIGURE request primitive. When the MS SNDCP receives this primitive, it shall replace the previously recorded value with the new value and confirm its arrival by issuing the SN-NSAPI CONFIGURE confirm primitive.

If the SNDCP service user is making a long-term change to the data priority of all its N-PDUs for a particular PDP context, it should alter the NSAPI data priority.

NOTE: The NSAPI data priority is intended to aid the MS in adjusting a long-term default data priority, and the SNDCP service user should not attempt to use the SN-NSAPI CONFIGURE request primitive to follow short-term changes in data priority.

#### 28.3.5.5.4 Changing the MS default data priority

This clause shall be applicable only to MSs and SwMIs which support data priority.

When the MS SNDCP needs to transmit an SN-DATA TRANSMIT REQUEST PDU, when the SNDCP service user requests a change in an NSAPI data priority, or when a CONTEXT\_READY timer expires or is stopped, the MS SNDCP should compute a preferred default data priority.

The MS SNDCP should compute the preferred default data priority by examination of the recorded "NSAPI data priority" for each PDP context that is actively sending or receiving data (i.e. for each PDP context with an active CONTEXT\_READY timer, or, if CONTEXT\_READY timers are not supported, for the PDP context that is presently keeping the READY timer active). The MS SNDCP may include in its computation the "mean active throughput" values of those PDP contexts which are actively attempting to transmit N-PDUs. The MS's preferred default data priority should be an estimate of the modal value of the data priority of the SN-DATA or SN-UNITDATA PDUs that the MS currently expects to transmit.

If the MS's preferred default data priority is different from the current "MS default data priority", the MS SNDCP may request a change to MS default data priority by sending an SN-DATA-PRIORITY REQUEST PDU to the SwMI (it should first transmit any pending SN-DATA TRANSMIT REQUEST PDU). The SwMI shall respond to the SN-DATA-PRIORITY REQUEST PDU with an SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU accepting or rejecting the request, refer to figure 28.42. The MS SNDCP shall not change its value of MS default data priority if the request is rejected. If the request is accepted, the MS SNDCP shall set its value of MS default data priority to the value included with the SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU. (The SwMI need not set this to the value requested by the MS). If the request is accepted and SNDCP is in the READY state, the MS SNDCP shall inform MLE of the new value of MS default data priority using the MLE-CONFIGURE request primitive.

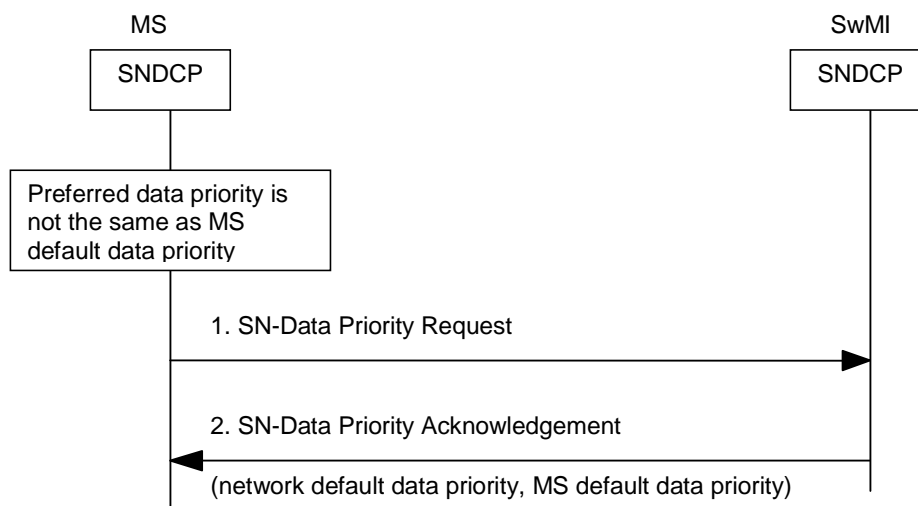

Figure 28.42: SNDCP changes MS default priority

The MS shall not transmit an SN-DATA-PRIORITY REQUEST PDU containing the same information as a previously-transmitted SN-DATA-PRIORITY REQUEST PDU or requesting the same or lower MS default data priority than a previously-transmitted SN-DATA-PRIORITY REQUEST PDU until time DATA\_PRIORITY\_REQUEST\_WAIT has elapsed since the previous transmission of the SN-DATA-PRIORITY REQUEST PDU.

The SwMI may decide to change the MS default data priority for its own reasons. If it changes the MS default data priority it should inform the MS concerned using an individually-addressed SN-DATA-PRIORITY INFORMATION PDU. If the MS default data priority is changed and SNDCP is in the READY state and has informed MLE that the MS default data priority has a value other than "not applicable", the MS SNDCP shall inform MLE using the "MS default data priority" parameter in the MLE-CONFIGURE request primitive.

#### 28.3.5.5.5 Short-term data priorities

This clause shall be applicable only to MSs which support data priority.

SN-DATA and SN-UNITDATA request primitives from the SNDCP service users may include a data priority parameter.

When the MS SNDCP sends an SN-DATA PDU or SN-UNITDATA PDU to the MLE in an MLE-UNITDATA request primitive, the MS SNDCP shall include a data priority parameter in the MLE-UNITDATA request primitive. This data priority parameter shall be set as follows:

- if the SN-DATA PDU or SN-UNITDATA PDU is scheduled (see clause 28.3.5.6) then the data priority parameter shall be set to "undefined" (this includes data which is surplus to the schedule);
- if the SN-DATA PDU or SN-UNITDATA PDU is "initial scheduled data" (see clause 28.3.5.6) then the data priority parameter may be set to "undefined" or may be set using the following methods for data which is not scheduled;
- if the SN-DATA PDU or SN-UNITDATA PDU is not scheduled and there was no data priority parameter in the matching SN-SAP primitive, then:
  - if the "NSAPI data priority" is "undefined" and the MS default data priority is "undefined" then the data priority parameter in the MLE-UNITDATA request primitive shall not take the value "undefined" but should be set to the value "2";
  - if the "NSAPI data priority" is "undefined" and the MS default data priority is not "undefined" then the data priority parameter in the MLE-UNITDATA request primitive shall take the value of the MS default data priority;
  - if the "NSAPI data priority" is not "undefined" then the data priority parameter in the MLE-UNITDATA request primitive shall take its value from the "NSAPI data priority";
- if the SN-DATA PDU or SN-UNITDATA PDU is not scheduled and there was a data priority parameter in the matching SN-SAP primitive then the data priority parameter in the MLE-UNITDATA request primitive shall take its value from the data priority parameter in the matching SN-SAP primitive.

When sending an SN-DATA or SN-UNITDATA PDU, the MS SNDCP shall set the packet data flag in the MLE-UNITDATA request primitive to indicate that the PDU contains packet data. (For all other PDUs, the MS SNDCP shall set the flag to indicate that the PDU does not contain packet data.)

#### 28.3.5.5.6 Short term data priority control

This clause shall be applicable only to MSs which support data priority.

The "Layer 2 data priority lifetime" and "Layer 2 data priority signalling delay" timer values and the "Data priority random access delay factor" are used by layer 2 for control of the short term data priority.

Whenever these items are received by the MS SNDCP in the "data priority details" information element of a SN-ACTIVATE PDP CONTEXT ACCEPT, SN-DATA-PRIORITY INFORMATION or SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU, the MS SNDCP shall inform MLE of their values using the MLE-CONFIGURE request primitive.

The SwMI should transmit broadcast-addressed SN-DATA-PRIORITY INFORMATION PDUs if it wishes to change or update MSs' recorded values of any of the items in the "data priority details" information element.

### 28.3.5.5.7 Data priority of SN-DATA TRANSMIT REQUEST and SN-RECONNECT PDUs

This clause shall be applicable only to MSs which support data priority.

If the current cell supports data priority, the MS SNDCP may ask the MLE to include data priority with an SN-DATA TRANSMIT REQUEST PDU or SN-RECONNECT PDU by setting the MLE data priority flag parameter to "MLE data priority signalling required" in the MLE-UNITDATA request primitive carrying the SNDCP PDU, and including a data priority parameter with a defined value (i.e. shall not be set to "undefined"). The data priority parameter should be set to the highest data priority of those SN-DATA PDUs which are waiting to be transmitted using the NSAPI or NSAPIs included in the SN-DATA TRANSMIT REQUEST or SN-RECONNECT PDU.

**NOTE:** This causes the MS MLE to inform the SwMI that the PDCH request implicit in the SNDCP PDU should be given an appropriate data priority by the SwMI, with the objective of reducing the MS's waiting time for access to the PDCH.

The MLE data priority flag shall be set to "MLE data priority signalling not required" for all PDUs other than SN-DATA TRANSMIT REQUEST and SN-RECONNECT, and for all PDUs when the current cell does not support data priority.

### 28.3.5.6 Scheduled Access

SNDCP provides a scheduled data service known as scheduled access. Scheduled access is available on the uplink for the acknowledged data service and the unacknowledged data service (basic link). It is intended for use by real-time class data and telemetry class data generated by an MS SNDCP service user at regular intervals. Use of a schedule reduces the need for the MS to make random access requests to send its scheduled data, and therefore increases channel efficiency. Scheduled access is available only when SNDCP supports QoS negotiation during PDP context activation.

If an MS SNDCP service user specifies a schedule in an SN-NSAPI ALLOC request primitive, if the MS and SwMI support QoS negotiation during PDP context activation and if the MS supports scheduled access, the MS SNDCP shall request a schedule in the QoS information element of the SN-ACTIVATE PDP CONTEXT DEMAND PDU.

When requesting a schedule, the MS SNDCP shall convert the N-PDU sizes specified by the MS SNDCP service user into SN-DATA or SN-UNITDATA PDU sizes, taking into account the SNDCP header and the effects of IP header compression and data compression, and, in the case of real-time class data, the number of transmission repetitions it requires for each SN-UNITDATA PDU.

If the schedule is agreed by the SwMI, when the SwMI receives a SN-DATA or SN-UNITDATA PDU from the MS for that PDP context, the SwMI shall commence or continue sending regular slot grants to the MS with the repetition period and timing accuracy agreed during the PDP context negotiation.

When the MS SNDCP sends an SN-DATA or SN-UNITDATA PDU to MLE from a PDP context with a schedule for the first time after activation of that PDP context, it shall inform MLE that it requires schedule timing prompts to be started for the relevant NSAPI (using the schedule repetition information parameter in an MLE-CONFIGURE request primitive).

The MS SNDCP may inform MLE that the schedule timing prompts for a particular PDP context can be stopped (using the schedule repetition information parameter in the MLE-CONFIGURE request primitive) when the PDP context containing the schedule is deactivated or when SNDCP returns to the STANDBY state or if the MS SNDCP is informed that the SwMI has suspended or cancelled the schedule.

If MS SNDCP decides to resume use of a schedule after it has informed MLE that the schedule timing prompts may be stopped, it shall inform MLE that it requires schedule timing prompts to be started for the relevant NSAPI when it sends to MLE the next SN-DATA or SN-UNITDATA PDU for that PDP context.

If a schedule has been agreed for a PDP context, the MLE-UNITDATA request primitive carrying the first SN-DATA or SN-UNITDATA PDU from that PDP context following activation of the PDP context shall indicate in the "scheduled data status" parameter that the SN-DATA or SN-UNITDATA PDU is "initial scheduled data". The "scheduled data status" of subsequent SN-DATA or SN-UNITDATA PDUs for that PDP context shall be set to "scheduled data" and the MLE-UNITDATA request primitives shall include the "maximum schedule interval" for the PDP context. (The maximum schedule interval is sum of the schedule repetition period and the schedule timing error.)

If there is a substantial gap in the arrival of N-PDUs from the SNDCP service user, such that the MS SNDCP has no data to transmit for a particular schedule for several schedule periods (for example, when SNDCP returns to the STANDBY state) the MS SNDCP may indicate to the MLE that the first SN-DATA or SN-UNITDATA PDU after the gap is "initial scheduled data". The subsequent SN-DATA or SN-UNITDATA PDUs shall be marked as "scheduled data".

NOTE 1: The indication that an SN-DATA or SN-UNITDATA PDU is "initial scheduled data" allows layer 2 to speed up the re-establishment of a schedule in the event that the SwMI has paused the scheduled slot grants during a gap in the MS's use of the scheduled slot grants.

"Initial scheduled data" SN-DATA and SN-UNITDATA PDUs may be sent to the MLE immediately. "Scheduled data" SN-DATA and SN-UNITDATA PDUs shall be buffered by the MS SNDCP until receipt of an MLE-INFO indication request primitive containing a "schedule timing prompt" parameter for the relevant NSAPI.

SN-DATA request and SN-UNITDATA request primitives containing an N-PDU for a PDP context with a schedule may be labelled "not surplus to schedule" or "surplus to schedule" by the SNDCP service user. N-PDUs which are surplus to schedule are N-PDUs in excess of the number of N-PDUs per schedule interval which the MS agreed with the SwMI during the PDP context activation. The MS SNDCP limits transmission of "not surplus to schedule" N-PDUs to the agreed number of N-PDUs per schedule period. If the application delivers these N-PDUs irregularly (e.g. more than one schedule period early), the MS SNDCP buffers them and delivers them at the agreed schedule intervals and numbers. The MS SNDCP does not limit the number of N-PDUs labeled "surplus to schedule", apart from delaying them until arrival of the next schedule timing signal from MLE.

When the relevant schedule timing prompt is received, the MS SNDCP shall start sending its buffered N-PDUs to the MLE in order of receipt. It shall count the number of those N-PDUs that arrive for this PDP context since the last scheduled transmission having no label or having the label "not surplus to schedule", and shall stop sending buffered N-PDUs for this PDP context if transmission of the next N-PDU would cause the count to exceed the agreed number of N-PDUs per schedule for this schedule.

New N-PDUs arriving after this time shall be buffered until arrival of the next schedule timing prompt.

NOTE 2: This permits the MS SNDCP to transmit "surplus to schedule" N-PDUs on the current schedule timing prompt without delaying following N-PDUs scheduled to be sent on the next schedule timing prompt.

If SNDCP re-negotiates the period of a schedule, the MS SNDCP shall inform MLE that it requires the schedule timing prompts for the relevant NSAPI to be re-started by issuing the new schedule repetition information in an MLE-CONFIGURE request primitive.

The data priority of a "scheduled data" SN-DATA or SN-UNITDATA PDU shall be set to "undefined". "Initial scheduled data" SN-DATA or SN-UNITDATA PDUs may be given a data priority.

If the lower layers fail to provide an MLE-REPORT indication primitive indicating transmission or failure of an SN-UNITDATA PDU containing a scheduled real-time class N-PDU by the time the MS is due to send the next N-PDU in the schedule, the MS SNDCP may attempt to cancel the previous unsent SN-UNITDATA PDU for that PDP context by issuing an MLE-CANCEL request primitive.

If SNDCP decides to cancel N-PDUs, it should preferentially cancel N-PDUs with low "data importance" (as indicated in the SN-DATA or SN-UNITDATA request primitives).

When an MS SNDCP service user stops using a PDP context temporarily it may notify the MS SNDCP in a SN-NSAPI MODIFY request primitive advising that it is pausing use of the schedule or of the entire PDP context. In either case, if the current cell supports QoS negotiation during PDP context activation, the MS SNDCP shall notify the SwMI SNDCP by sending an SN-MODIFY PDP CONTEXT USAGE PDU to the SwMI.

The SwMI may pause a schedule if the MS SNDCP notifies it that it is pausing use of the schedule or PDP context.

The SwMI may also pause a schedule if the MS stops using the scheduled resource for a sufficient period of time (the time is not specified in this document).

The SwMI pauses a schedule by ceasing to provide scheduled slot grants for that PDP context. The SwMI shall resume provision of slot grants for a paused schedule when it next receives an SN-DATA or SN-UNITDATA PDU for that PDP context.

The SwMI may suspend a schedule for a particular PDP context:

- if the SwMI needs to grant resource to an MS wishing to transmit N-PDUs with data priority 7; or
- if the SwMI can no longer provide sufficient resource to support the agreed schedule.

On a cell supporting QoS negotiation during PDP context activation, the SwMI shall suspend a schedule by sending an SN-MODIFY PDP CONTEXT AVAILABILITY PDU to the MS with the "PDP context availability" information element set to "schedule suspended". When the MS SNDCP receives this message, it shall notify the SNDCP service user that the schedule is suspended by issuing an SN-NSAPI MODIFY indication primitive. The MS SNDCP may attempt to renegotiate the schedule when this occurs. SNDCP may delete or cancel N-PDUs received for this PDP context from the SNDCP service user while the schedule is suspended (in which case it shall inform the SNDCP service user by issuing SN-DELIVERY indication primitives).

When the SwMI is able to support a suspended schedule again and the PDP context is still activated, the SwMI shall inform the MS by sending an SN-MODIFY PDP CONTEXT AVAILABILITY PDU with the "PDP context availability" information element set to "PDP context available for use". When the MS SNDCP receives this message it shall notify the SNDCP service user that the PDP context is available by issuing the SN-NSAPI MODIFY indication primitive.

When an MS with an agreed schedule reselects a cell which does not support QoS negotiation during PDP context activation, the MS shall regard the schedule as suspended, shall stop the relevant CONTEXT-READY timer, and shall notify the SNDCP service user that the PDP context is suspended by issuing an SN-NSAPI MODIFY indication primitive. SNDCP may delete or cancel N-PDUs received from the SNDCP service user for this PDP context while the schedule is suspended, in which case it shall inform the SNDCP service user by issuing SN-DELIVERY indication primitives. When the MS returns to a cell supporting QoS negotiation during PDP context activation, the MS should regard the schedule as available and may notify the SNDCP service user that the PDP context is available by issuing the SN-NSAPI MODIFY indication primitive.

The SwMI may cancel a schedule if it wishes to permanently reallocate the scheduled resource.

The SwMI shall cancel a schedule by sending the MS a SN-MODIFY PDP CONTEXT REQUEST PDU whose QoS information element does not include the schedule (e.g. the SwMI could send a one-bit QoS information element if it is now only providing a background class QoS with unspecified throughput, reliability and delay). The MS SNDCP shall reply to this with a SN-MODIFY PDP CONTEXT RESPONSE PDU and shall notify the SNDCP service user that the schedule has been cancelled by issuing a SN-NSAPI MODIFY indication primitive. After the schedule has been cancelled, the MS SNDCP may cancel or delete N-PDUs queued or received for this PDP context from the SNDCP service user (in which case it shall inform the SNDCP service user by issuing SN-DELIVERY indication primitives). On a cell not supporting PDP context modification, the SwMI cannot cancel the schedule but may choose to deactivate the PDP context.

### 28.3.6 Packet data paging mechanism

A paging mechanism has been defined within SNDCP to provide the following three functions:

- to allow a SwMI to determine the current location of a MS which is in state STANDBY (or state RESPONSE-WAITING), in order to deliver data;
- to provide a method for the SwMI to discover which channels the MS can use in advance of delivering data to the MS (the MS-MLE adds advice about usable channels to the paging response from the MS SNDCP);
- to provide a mechanism by which a SwMI may indicate that there is outbound data awaiting delivery to this MS and allow the MS to indicate whether it is available to accept this data.

There are three main scenarios where the paging mechanism may be used. Firstly where data arrives in the SwMI for a MS which is in STANDBY (or RESPONSE-WAITING) state, and if the SwMI is unsure of the exact location of the MS (e.g. due to there being multiple cells per registration area), then the SwMI may page the MS. Secondly where data arrives in the SwMI for a MS which is presently in STANDBY (or RESPONSE-WAITING) state and the SwMI wishes to discover which (if any) non-conforming channels the MS is presently able to use for receiving the data, then the SwMI may page the MS. Thirdly where data arrives in the SwMI for a MS which is in STANDBY state, and the SwMI wishes to first check to see if the MS is available for packet data service, then the SwMI may page the MS. This third scenario may be useful when considering service interaction with Type B, C and D of MS. This paging mechanism allows a MS to decide whether it wishes to drop its current service in order to switch to the packet data service.

Upon reception of a page request from the SwMI, the MS SNDCP entity may act in one of the following ways:

- 1) Where the SwMI indicates that no SNDCP response is requested, then the MS SNDCP entity shall take no further action. In this case the page request shall be carried using the basic link acknowledged service.

NOTE 1: As the page request is carried using the basic link acknowledged service, hence by acknowledging this basic link message, the MS is implicitly responding to the page.

- 2) Where the SwMI indicates that a SNDCP response is requested, the MS SNDCP entity may respond indicating whether it is available or temporarily unavailable for packet data service. The MS may set the "Stealing Permission" parameter in the MLE-UNITDATA request primitive used to pass the SN-PAGE RESPONSE PDU to the MLE, to "steal immediately".

NOTE 2: If the MS is on a cell where a subscriber class mismatch exists (see clause 16.4.9) or on a not-permitted cell (see clause 18.3.5.1.5), the MS SNDCP should send no response to a page request.

- 3) Where the MS does not have an active PDP context, the MS SNDCP entity may respond by the SN-DEACTIVATE PDP CONTEXT DEMAND PDU initiating the MS originated PDP context deactivation procedure (see clause 28.3.3.6.1).

NOTE 3: The MS may respond with the "Deactivation type" set to "Deactivate all NSAPIs" if no active PDP context exist. If PDP contexts do exist at the MS, the MS may respond with the "Deactivation type" set to "Deactivate NSAPI given in the PDU" if the NSAPI identified in the SN-PAGE REQUEST PDU is not recognized by the MS.

Figure 28.43 shows the scenario where the MS SNDCP entity responds to a page received from the SwMI.

Figure 28.43: SwMI Pages MS, MS SNDCP entity responds

### 28.3.7 TETRA IP user authentication

Figure 28.44 illustrates the reference model of IP user authentication when using PPP and RADIUS protocols, refer to IETF RFC 1661 [30] and IETF RFC 2865 [37]. In the model an AAA server and the RADIUS protocol are used to verify the user access. Other alternatives for the model are also possible. For instance inside the SwMI there could be a user authentication entity to provide the same functionality as the external AAA server.

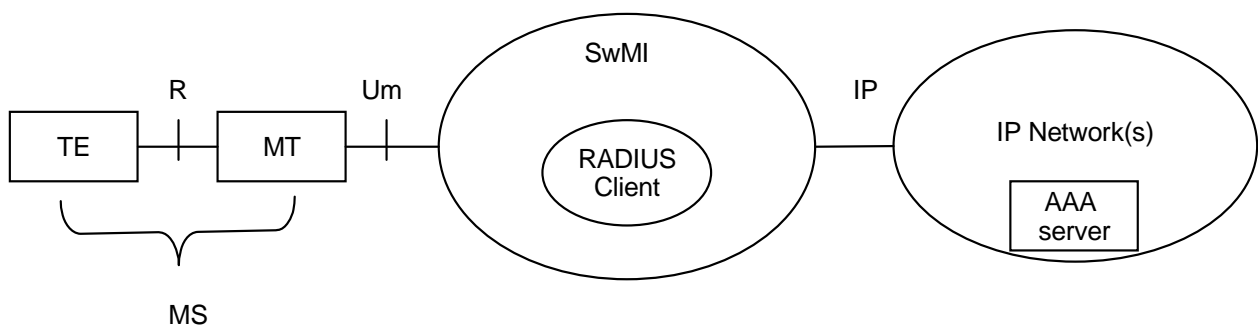

Figure 28.44: IP user authentication model

Following assumptions are made:

- PPP is the link layer protocol used between a TETRA Terminal Equipment (TE) and a TETRA Mobile Termination (MT);
- there is a requirement to authenticate the TE using PAP or CHAP, refer to IETF RFC 1994 [34];
- the TE is the peer that shall be authenticated, and the MT is the authenticator, using the terminology defined in ISO/IEC 8348 [i.7];
- there is a requirement to support the PPP authentication with a centralized AAA server which is accessed by RADIUS protocol as defined in IETF RFC 2865 [37];
- the PAP or CHAP authentication information collected in the MT is forwarded over the TETRA Air Interface to the TETRA SwMI;
- inside the TETRA SwMI is a RADIUS client entity which forwards the authentication information to the external AAA server.

Figure 28.45 illustrates the phases of a packet data context setup upon a successful authentication with CHAP. Corresponding signalling using PAP authentication would be slightly more straightforward.

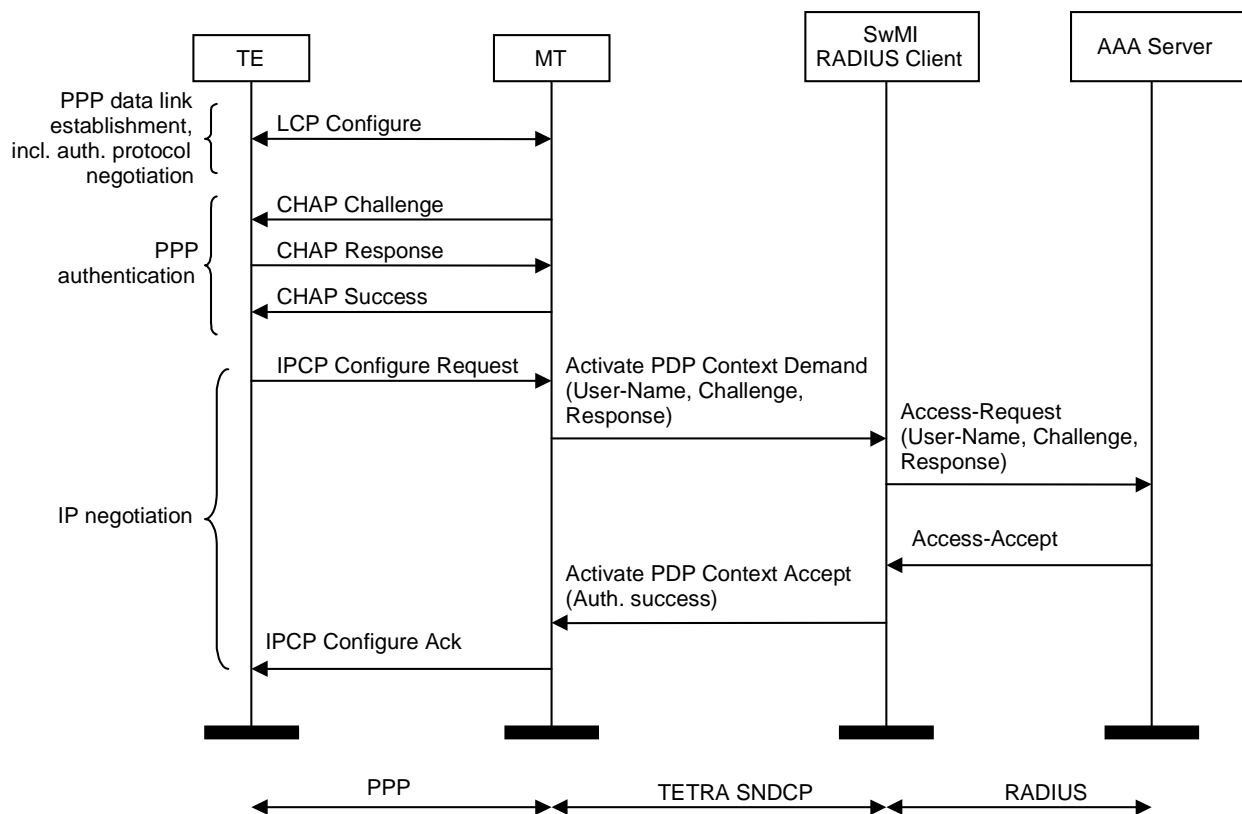

Figure 28.45: A successful authentication with CHAP

Following steps clarifies the figure above:

1. PPP/LCP negotiates the Maximum-Receive-Unit and authentication options;
2. When using CHAP (or PAP), the TE authenticates itself to the MT, which stores the information (username, challenge and response, or password when using PAP) and sends an accept to TE;
3. TE requests IP configuration from the MT using PPP/PCP, either defining a static address, or requesting an address from the network;
4. MT sends an ACTIVATE PDP CONTEXT DEMAND PDU to SwMI, containing in the Protocol configuration option information element the authentication and configuration information it has collected;
5. RADIUS client in SwMI sends an Access-Request to AAA Server using RADIUS protocol;
6. AAA Server sends an Access-Accept to RADIUS Client;
7. SwMI sends an ACTIVATE PDP CONTEXT ACCEPT PDU to MT;
8. MT sends an IPCP Configure Ack to TE and the link is open (or dropped if negotiation failed).

### 28.3.8 TETRA Packet data over the air provisioning

As indicated in figure 28.44, the TETRA reference model in many ways resembles the reference model used by many IP service providers. Here, the PPP establishment mechanisms are used as a flexible, easily expandable way to provision essential information to the dial up client at connection establishment. Similar information is required at the TE/MT in the TETRA environment, and the TETRA standard therefore allows for such parameters to be provisioned to the TE/MT at context activation.

This information should be transferred to the TE/MT contained in an IPCP Configuration-Ack within the Protocol configuration options information element in the SN-ACTIVATE PDP CONTEXT ACCEPT PDU. The SwMI may include IPCP configuration options specifying (but not limited to):

- Primary and secondary DNS servers.
- Primary and secondary NBNS servers.

The MT shall be prepared to receive Protocol configuration options information elements with Protocol identity set to IPCP (8021H). The MT may ignore the IPCP protocol or IPCP configuration options.

NOTE: Ignoring received information is dissimilar to normal PPP behaviour but required here as the MT can not reject received information.

### 28.3.9 QoS filters

The MS shall not include a QoS filter specification in the QoS information element when requesting activation of a primary PDP context.

When the MS requests activation of a secondary PDP context it may include a QoS filter specification in the QoS information element. If the SwMI does not support the proposed QoS filter, either the SwMI shall accept the activation request and propose an alternative QoS filter specification or the SwMI shall reject the activation request (e.g. with reject cause "QoS filter type not supported" or "Specified QoS filter not supported").

If the MS does not include a QoS filter specification in the activation request for a secondary PDP context, either the SwMI shall accept the activation request and shall generate an automatic QoS filter for that PDP context (see clause 28.1), or the SwMI shall reject the activation request with reject cause "Automatic QoS filter not supported".

After a secondary PDP context has been activated, the MS may ask the SwMI to modify the QoS filter by sending the SwMI an SN-MODIFY PDP CONTEXT REQUEST PDU. The MS may ask the SwMI to:

- add additional items to the existing the QoS filter;
- remove items from the existing QoS filter; or

- replace the existing QoS filter with a different QoS filter.

Depending on the value of the QoS filter operation information element in the QoS filter information element, the SwMI shall add the QoS filter in the SN-MODIFY PDP CONTEXT REQUEST PDU to the existing QoS filter, or replace any existing QoS filter for the specified PDP context with the new QoS filter, or remove the QoS filter from the specified PDP context. An MS should not attempt removal of a QoS filter that it has not previously established.

If the SwMI is using an automatic QoS filter for a particular PDP context when it receives a request from the MS to replace the QoS filter for that same PDP context, the SwMI shall stop using that automatic QoS filter. If the SwMI is using an automatic QoS filter for a particular PDP context when it receives a request from the MS to add a QoS filter to that same PDP context, the SwMI shall, if it accepts the request, combine the newly requested QoS filter with the automatic QoS filter and use the new combined QoS filter with that PDP context until the MS replaces the existing QoS filter for that PDP context with a new QoS filter.

Where a downlink data packet matches more than one automatic QoS filter, the SwMI shall use the PDP context whose automatic QoS filter was most recently updated with the matching item.

Where a downlink data packet matches more than one explicitly-defined QoS filter, the SwMI shall use the PDP context whose explicitly-defined QoS filter was most recently updated with the matching item.

Where a downlink data packet matches an automatic QoS filter and an explicitly-defined QoS filter, the SwMI shall use the PDP context with the explicitly-defined QoS filter.

**EXAMPLE:** A SwMI has automatic QoS filters for NSAPIs 2 and 3 that presently accept data packets for downlink destination ports 1005 and 1006 respectively. The SwMI also has an explicitly defined QoS filter for NSAPI 4 that accepts data packets for downlink destination port 1007. The SwMI now receives some uplink packets via NSAPI 3 from source ports 1005 and 1007, so the SwMI updates NSAPI 3's QoS filter to accept packets for downlink destination ports 1005, 1006 and 1007. Shortly afterwards, the SwMI receives a downlink packet for destination port 1007. The SwMI sends this packet to the MS via NSAPI 4 because NSAPI 4's explicitly-defined QoS filter takes precedence over the automatic QoS filter of NSAPI 3. Then the SwMI receives a downlink packet for destination port 1005. The SwMI sends this packet to the MS via NSAPI 3 because port 1005 was added to NSAPI 3 more recently than to NSAPI 2. When the filter on NSAPI 3 is subsequently removed, the SwMI sends packets for downlink destination port 1005 via NSAPI 2.

If the MS includes a QoS filter specification in a secondary PDP context activation or modification request and the SwMI accepts the activation or modification request but includes no QoS filter specification in its response, the MS shall assume that the requested QoS filter has been applied by the SwMI.

If the MS does not include a QoS filter specification in a secondary PDP context activation request and the SwMI accepts the activation request but includes no QoS filter specification in its response, the MS shall assume that an automatic QoS filter has been applied by the SwMI.

If the MS includes a QoS filter specification in a PDP context activation or modification request and the SwMI accepts the activation or modification request, but includes in its response a QoS filter specification which differs from the QoS filter requested by the MS, the MS shall assume that the QoS filter specified by the SwMI has been applied.

## 28.4 SN-PDU formats

### 28.4.0 General

The general format of the PDU encoding is as defined in annex E of the present document.

The information elements shall be transmitted in the order specified by the table with the top information element being transmitted first. The content of an information element is represented by a binary value and the most significant bit of that binary value shall be transmitted first.

The information contained in the PDU description tables which follow corresponds to the following key:

- Length: length of the information element in bits;
- Type: information element type (1, 2 or 3) as defined in annex E;

- C/O/M: conditional/optional/mandatory information in the PDU;
- Remark: comment.

## 28.4.1 PDU priority

At the transmitting end the message PDU priority management at SNDCP level is done before any other operations. Each PDU priority has its own queue that is mapped to the corresponding queue in LLC (MLE passes messages without changing their order). By doing so, for instance, a long file transfer PDU can be quickly bypassed by any other message that has a higher PDU priority. Eight PDU priority levels are used, number 7 representing the highest PDU priority. The PDU priorities for SN-PDUs shall be set according to table 28.22.

**Table 28.22: PDU priority for SN-PDUs**

| SN-PDU  | PDU priority |
|---|--------------|
| SN-ACTIVATE PDP CONTEXT DEMAND  | 4            |
| SN-DEACTIVATE PDP CONTEXT DEMAND  | 4            |
| SN-ACTIVATE PDP CONTEXT ACCEPT  | 4            |
| SN-ACTIVATE PDP CONTEXT REJECT  | 4            |
| SN-DEACTIVATE PDP CONTEXT ACCEPT  | 4            |
| SN-DATA-PRIORITY REQUEST  | 4            |
| SN-DATA-PRIORITY ACKNOWLEDGEMENT  | 4            |
| SN-DATA-PRIORITY INFORMATION  | 4            |
| SN-MODIFY PDP CONTEXT DEMAND  | 4            |
| SN-MODIFY PDP CONTEXT RESPONSE  | 4            |
| SN-MODIFY PDP CONTEXT AVAILABILITY  | 4            |
| SN-MODIFY PDP CONTEXT USAGE   | 4            |
| SN-UNITDATA   | see note     |
| SN-DATA   | see note     |
| SN-DATA TRANSMIT REQUEST  | see note     |
| SN-DATA TRANSMIT RESPONSE   | see note     |
| SN-RECONNECT  | 4            |
| SN-PAGE REQUEST   | 4            |
| SN-PAGE RESPONSE  | 4            |
| SN-END OF DATA  | 4            |
| SN-NOT SUPPORTED  | 4            |
| NOTE: The maximum value for PDU priority is defined in SN-ACTIVATE PDP CONTEXT ACCEPT PDU "PDU priority max" information element for each NSAPI. The value used in the MLE-UNITDATA request primitive is given in the SN-DATA/UNITDATA request primitive. If the value given by the higher layer is higher than the "PDU priority max" information element indicates, then the PDU priority is decreased by the SNDCP to the value indicated in the "PDU priority max" information element. If the value is not given in the SN-DATA/UNITDATA request primitive, then the SNDCP uses value indicated in the "PDU priority max" information element. |              |

At the receiver end there is no need for queuing mechanism.

## 28.4.2 Maximum N-PDU size

The maximum N-PDU size is assigned by the SwMI at context activation using the parameter "Maximum transmission unit". This value represents the maximum N-PDU size which is allowed. This size refers to the maximum size of a N-PDU prior to the addition of the SNDCP header and the application of any compression.

The Maximum transmission unit should always be less than the Maximum size of a TL-SDU, which is negotiated during advanced link setup. Hence where the SwMI sets Maximum transmission unit to 1 500 octets at context activation, then the negotiated maximum size of TL-SDU at advanced link setup should be 2 048 octets.

### 28.4.3 PDU not supported

In case the receiving MS or SwMI SNDCP entity receives an unknown SN PDU, the receiving entity should send the SN-NOT SUPPORTED PDU. The behaviour of the requesting party when receiving SN-NOT SUPPORTED PDU is outside the scope of the present document. The meaning of this functionality is only to maintain backward compatibility of the systems.

### 28.4.4 SN PDU description tables

#### 28.4.4.1 SN-ACTIVATE PDP CONTEXT ACCEPT

SN-ACTIVATE PDP CONTEXT ACCEPT PDU shall contain information elements as defined in table 28.23.

- Message: SN-ACTIVATE PDP CONTEXT ACCEPT PDU
- Response to: SN-ACTIVATE PDP CONTEXT DEMAND PDU
- Response expected: -
- Short description:

**Table 28.23: SN-ACTIVATE PDP CONTEXT ACCEPT PDU contents**

| Information element  | Length | Type | C/O/M | Remark                         |
|--|--------|------|-------|--------------------------------|
| SN PDU type  | 4      | 1    | M     | SN-ACTIVATE PDP CONTEXT ACCEPT |
| NSAPI  | 4      | 1    | M     |                                |
| PDU priority max   | 3      | 1    | M     |                                |
| READY timer  | 4      | 1    | M     |                                |
| STANDBY timer  | 4      | 1    | M     |                                |
| RESPONSE_WAIT timer  | 4      | 1    | M     |                                |
| Type identifier in accept  | 3      | 1    | M     |                                |
| IP Address IPv4  | 32     |      | C     | see note 1                     |
| PCOMP negotiation  | 8      | 1    | M     |                                |
| Number of Van Jacobson compression state slots   | 8      |      | C     | see note 2                     |
| Number of compression state slots, TCP   | 8      |      | C     | see note 3                     |
| Number of compression state slots, non-TCP   | 16     |      | C     | see note 3                     |
| Maximum interval between full headers  | 8      |      | C     | see note 3                     |
| Maximum time interval between full headers   | 8      |      | C     | see note 3                     |
| Largest header size in octets that may be compressed   | 8      |      | C     | see note 3                     |
| Maximum transmission unit  | 3      | 1    | M     |                                |
| SNDCP network endpoint identifier  | 16     | 2    | O     | see note 4                     |
| SwMI IPv6 information  | 98     | 2    | O     |                                |
| SwMI Mobile IPv4 information   | 71     | 2    | O     |                                |
| DCOMP negotiation  | varies | 3    | O     | see note 5                     |
| Protocol configuration options   | varies | 3    | O     | see note 6                     |
| Data priority details  | 24     | 3    | O     |                                |
| QoS  | varies | 3    | O     |                                |
| <p>NOTE 1: Shall be conditional on the value of Type Identifier in Accept (TIA):</p> <ul style="list-style-type: none"> <li>- when TIA = 1 or 2 the information element shall be present;</li> <li>- for all other values of TIA the information element shall not be present.</li> </ul> <p>NOTE 2: Shall be conditional on the value of bit 1 (LSB) of PCOMP negotiation:</p> <ul style="list-style-type: none"> <li>- when bit 1 of PCOMP negotiation = 0 the information element shall not be present;</li> <li>- when bit 1 of PCOMP negotiation = 1 the information element shall be present.</li> </ul> <p>NOTE 3: Shall be conditional on the value of second LSB of PCOMP negotiation:</p> <ul style="list-style-type: none"> <li>- when bit 2 of PCOMP negotiation = 0 the information element shall not be present;</li> <li>- when bit 2 of PCOMP negotiation = 1 the information element shall be present.</li> </ul> <p>NOTE 4: For usage, refer to clause 28.3.3.3.</p> <p>NOTE 5: There may be more than one DCOMP negotiation information element if more than one compression mechanism is assigned for a single NSAPI.</p> <p>NOTE 6: The maximum length shall be 128 octets.</p> |        |      |       |                                |

### 28.4.4.2 SN-ACTIVATE PDP CONTEXT DEMAND

SN-ACTIVATE PDP CONTEXT DEMAND PDU shall contain information elements as defined in table 28.24.

- Message: SN-ACTIVATE PDP CONTEXT DEMAND PDU
- Response to: -
- Response expected: SN-ACTIVATE PDP CONTEXT ACCEPT PDU  
/SN-ACTIVATE PDP CONTEXT REJECT PDU
- Short description:

**Table 28.24: SN-ACTIVATE PDP CONTEXT DEMAND PDU contents**

| Information element   | Length | Type | C/O/M | Remark                         |
|---|--------|------|-------|--------------------------------|
| SN PDU type   | 4      | 1    | M     | SN-ACTIVATE PDP CONTEXT DEMAND |
| SNDCP version   | 4      | 1    | M     |                                |
| NSAPI   | 4      | 1    | M     | see notes 1 and 2              |
| Address type identifier in demand   | 3      | 1    | M     | see note 3                     |
| IP Address IPv4   | 32     |      | C     | see note 4                     |
| NSAPI   | 4      |      | C     | see notes 5 and 6              |
| Packet data MS Type   | 4      | 1    | M     |                                |
| PCOMP negotiation   | 8      | 1    | M     |                                |
| Number of Van Jacobson compression state slots  | 8      |      | C     | see note 7                     |
| Number of compression state slots, TCP  | 8      |      | C     | see note 8                     |
| Number of compression state slots, non-TCP  | 16     |      | C     | see note 8                     |
| Maximum interval between full headers   | 8      |      | C     | see note 8                     |
| Maximum time interval between full headers  | 8      |      | C     | see note 8                     |
| Largest header size in octets that may be compressed  | 8      |      | C     | see note 8                     |
| Access point name index   | 16     | 2    | O     | see note 9                     |
| DCOMP negotiation   | varies | 3    | O     |                                |
| Protocol configuration options  | varies | 3    | O     | see note 10                    |
| QoS   | varies | 3    | O     |                                |
| <p>NOTE 1: The MS shall not use value 0.</p> <p>NOTE 2: Shall contain the NSAPI for the requested PDP context.</p> <p>NOTE 3: If the SwMI supports use of the QoS information element but does not support the use of secondary PDP contexts, and it receives an ATID value 101<sub>2</sub> it shall discard the remainder of this PDU and shall reject the MS's request with reject cause "Secondary PDP contexts not supported" (value 00011011<sub>2</sub>).</p> <p>NOTE 4: Shall be conditional on the value of Address Type Identifier in Demand (ATID):</p> <ul style="list-style-type: none"> <li>- when ATID = 0 the information element shall be present;</li> <li>- for any other value of the ATID the information element shall not be present.</li> </ul> <p>NOTE 5: Shall be conditional on the value of Address Type Identifier in Demand (ATID):</p> <ul style="list-style-type: none"> <li>- when ATID = 5 (Primary NSAPI (secondary PDP context requested)) the information element shall be present;</li> <li>- for any other value of the ATID the information element shall not be present.</li> </ul> <p>NOTE 6: Shall contain the NSAPI of the primary PDP context from which the requested secondary PDP context derives its PDP address.</p> <p>NOTE 7: Shall be conditional on the value of bit 1 (LSB) of PCOMP negotiation:</p> <ul style="list-style-type: none"> <li>- when bit 1 of PCOMP negotiation = 0 the information element shall not be present;</li> <li>- when bit 1 of PCOMP negotiation = 1 the information element shall be present.</li> </ul> <p>NOTE 8: Shall be conditional on the value bit 2 of PCOMP negotiation:</p> <ul style="list-style-type: none"> <li>- when bit 2 of PCOMP negotiation = 0 the information element shall not be present;</li> <li>- when bit 2 of PCOMP negotiation = 1 the information element shall be present.</li> </ul> <p>NOTE 9: The default value shall be "0000hex".</p> <p>NOTE 10: The maximum length shall be 128 octets.</p> |        |      |       |                                |

NOTE: Some combinations of the SN-ACTIVATE PDP CONTEXT DEMAND PDU that include the QoS information element may be transmitted without fragmentation in SCH/HU. For example:

- requesting a primary PDP context with no conditional information elements, with no optional information elements apart from the 1-bit version of the QoS information element, with a layer 2 reservation requirement and with an SSI (one unused SCH/HU bit);

- requesting a secondary PDP context with no conditional information elements, with no optional information elements apart from the 48-bit version of the QoS information element with asymmetric QoS and no QoS filter, with no layer 2 reservation requirement and with an event label (two unused SCH/HU bits);
- requesting a primary PDP context, with no conditional information elements apart from the number of Van Jacobson compression state slots, with no optional information elements apart from the 1-bit version of the optional QoS information element, with a layer 2 reservation requirement and with an event label (seven unused SCH/HU bits).

### 28.4.4.3 SN-ACTIVATE PDP CONTEXT REJECT

SN-ACTIVATE PDP CONTEXT REJECT PDU shall contain information elements as defined in table 28.25.

- Message: SN-ACTIVATE PDP CONTEXT REJECT PDU
- Response to: SN-ACTIVATE PDP CONTEXT DEMAND PDU
- Response expected: -
- Short description: -

**Table 28.25: SN-ACTIVATE PDP CONTEXT REJECT PDU contents**

| Information element            | Length | Type | C/O/M | Remark                         |
|--------------------------------|--------|------|-------|--------------------------------|
| SN PDU type                    | 4      | 1    | M     | SN-ACTIVATE PDP CONTEXT REJECT |
| NSAPI                          | 4      | 1    | M     |                                |
| Activation reject cause        | 8      | 1    | M     |                                |
| Protocol configuration options | varies | 3    | O     | see note                       |

NOTE: The maximum length shall be 128 octets.

### 28.4.4.4 SN-DATA

SN-DATA PDU shall contain information elements as defined in table 28.26.

- Message: SN-DATA PDU
- Response to: -
- Response expected: -
- Short description: SN-DATA PDU is used for acknowledged service.

**Table 28.26: SN-DATA PDU contents**

| Information element | Length | Type | C/O/M | Remark  |
|---------------------|--------|------|-------|---------|
| SN PDU type         | 4      | 1    | M     | SN-DATA |
| NSAPI               | 4      | 1    | M     |         |
| PCOMP               | 4      | 1    | M     |         |
| DCOMP               | 4      | 1    | M     |         |
| N-PDU               | varies | 1    | M     |         |

NOTE: The N-PDU length is defined by the length of the lower layer PDU. There shall be no O-bit after the N-PDU.

#### 28.4.4.4a SN-DATA-PRIORITY ACKNOWLEDGEMENT

SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU shall contain information elements as defined in table 28.27.

- Message: SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU
- Response to: SN-DATA-PRIORITY REQUEST PDU
- Response expected: -
- Short description: Used by SwMI in reply to request from the MS concerning data priority.

**Table 28.27: SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU contents**

| Information element  | Length | Type | C/O/M | Remark                           |
|--|--------|------|-------|----------------------------------|
| SN PDU type  | 4      | 1    | M     | SN-DATA-PRIORITY                 |
| Data priority sub-type   | 4      | 1    | M     | SN-DATA-PRIORITY ACKNOWLEDGEMENT |
| Data priority request result   | 1      | 1    | M     |                                  |
| Data priority details  | 24     | 1    | M     |                                  |
| MS default data priority   | 4      |      | C     | See note                         |
| NOTE: This information element shall be present only if the data priority request result information element indicates "Request accepted". The value of the MS default data priority information element may differ from that requested by the MS in the SN-DATA-PRIORITY REQUEST PDU. |        |      |       |                                  |

#### 28.4.4.4b SN-DATA-PRIORITY INFORMATION

SN-DATA-PRIORITY INFORMATION PDU shall contain information elements as defined in table 28.28.

- Message: SN-DATA-PRIORITY INFORMATION PDU
- Response to: -
- Response expected: -
- Short description: Used by SwMI to send MS information about data priority.

**Table 28.28: SN-DATA-PRIORITY INFORMATION PDU contents**

| Information element  | Length | Type | C/O/M | Remark                       |
|--|--------|------|-------|------------------------------|
| SN PDU type  | 4      | 1    | M     | SN-DATA-PRIORITY             |
| Data priority sub-type   | 4      | 1    | M     | SN-DATA-PRIORITY INFORMATION |
| Data priority details  | 24     | 1    | M     |                              |
| MS default data priority flag  | 1      | 1    | M     | See note 1                   |
| MS default data priority   | 4      |      | C     | See note 2                   |
| NOTE 1: This information element should be set to "0" if this PDU is sent to a group or broadcast address. |        |      |       |                              |
| NOTE 2: This information element shall be present only if "MS default data priority flag" = 1.             |        |      |       |                              |

### 28.4.4.4c SN-DATA-PRIORITY REQUEST

SN-DATA-PRIORITY REQUEST PDU shall contain information elements as defined in table 28.29.

- Message: SN-DATA-PRIORITY REQUEST PDU
- Response to: -
- Response expected: SN-DATA-PRIORITY ACKNOWLEDGEMENT PDU
- Short description: Used by MS to request data priority change or information.

**Table 28.29: SN-DATA-PRIORITY REQUEST PDU contents**

| Information element        | Length | Type | C/O/M | Remark                   |
|----------------------------|--------|------|-------|--------------------------|
| SN PDU type                | 4      | 1    | M     | SN-DATA-PRIORITY         |
| Data priority sub-type     | 4      | 1    | M     | SN-DATA-PRIORITY REQUEST |
| Data priority request type | 4      | 1    | M     |                          |

### 28.4.4.5 SN-DATA TRANSMIT REQUEST

SN-DATA TRANSMIT REQUEST PDU shall contain information elements as defined in table 28.30.

- Message: SN-DATA TRANSMIT REQUEST PDU
- Response to: -
- Response expected: SN-DATA TRANSMIT RESPONSE PDU (when SN-DATA TRANSMIT REQUEST PDU is sent by the MS)
- Short description:

**Table 28.30: SN-DATA TRANSMIT REQUEST PDU contents**

| Information element   | Length | Type | C/O/M | Remark                   |
|---|--------|------|-------|--------------------------|
| SN PDU type   | 4      | 1    | M     | SN-DATA TRANSMIT REQUEST |
| NSAPI   | 4      | 1    | M     |                          |
| Logical link status   | 1      | 1    | M     | see note 1               |
| Enhanced $\pi/4$ -DQPSK service (see note 5)  | 1      | 1    | M     | see note 1               |
| Resource request  | varies |      | C     | see note 2               |
| SNDCP network endpoint identifier   | 16     | 2    | O     | see note 3               |
| Reserved  | 20     | 2    | O     | see note 4               |
| NSAPI additional  | varies | 4    | O     | see notes 6 and 7        |
| NOTE 1: This information element has meaning only on uplink. The information element value shall be "0" on downlink in the present document.  |        |      |       |                          |
| NOTE 2: For usage refer to clause 28.3.5.2a. Shall be conditional on the value of Enhanced $\pi/4$ -DQPSK service information element: <ul style="list-style-type: none"> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 1 the Resource request information element shall be present;</li> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 0 the Resource request information element shall not be present.</li> </ul> |        |      |       |                          |
| NOTE 3: For usage refer to clause 28.3.3.3.   |        |      |       |                          |
| NOTE 4: Shall not be used in protocol defined in the present document.  |        |      |       |                          |
| NOTE 5: This was formerly known as the "enhanced service" information element.  |        |      |       |                          |
| NOTE 6: This information element may be included if the MS wishes to transmit data for more than one NSAPI. In combination with the "NSAPI" information element, it indicates to the SwMI those NSAPIs for which the MS wishes to transmit data.  |        |      |       |                          |
| NOTE 7: The sender of this PDU is not precluded from including the same NSAPI value in both the "NSAPI" information element and the "NSAPI for reconnection" information element. In the present document, the receiver shall ignore a second incidence of the same NSAPI.  |        |      |       |                          |

If MS supports the use of non-conforming PDCHs, the "channel advice flag" parameter in the MLE-UNITDATA request primitive containing this PDU should be set to "channel advice requested".

NOTE: Fragmentation will occur if this PDU is sent in SCH-Q/RA with an SSI and SNEI.

#### 28.4.4.6 SN-DATA TRANSMIT RESPONSE

SN-DATA TRANSMIT RESPONSE PDU shall contain information elements as defined in table 28.31.

- Message: SN-DATA TRANSMIT RESPONSE PDU
- Response to: SN-DATA TRANSMIT REQUEST PDU (MS to SwMI), SN-RECONNECT PDU
- Response expected: -
- Short description:

**Table 28.31: SN-DATA TRANSMIT RESPONSE PDU contents**

| Information element  | Length | Type | C/O/M | Remark                    |
|--|--------|------|-------|---------------------------|
| SN PDU type  | 4      | 1    | M     | SN-DATA TRANSMIT RESPONSE |
| NSAPI  | 4      | 1    | M     |                           |
| Accept/Reject  | 1      | 1    | M     |                           |
| Transmit response reject cause   | 8      |      | C     | see note 1                |
| SNDCP network endpoint identifier  | 16     | 2    | O     | see note 2                |
| NSAPI additional   | varies | 4    | O     | see notes 3 and 4         |
| NOTE 1: Shall be conditional on the value of the Accept/Reject information element: <ul style="list-style-type: none"> <li>- when the Accept/Reject = 0 the transmit response reject cause information element shall be present;</li> <li>- when the Accept/Reject = 1 the transmit response reject cause information element shall not be present.</li> </ul> |        |      |       |                           |
| NOTE 2: For usage refer to clause 28.3.3.3.  |        |      |       |                           |
| NOTE 3: This information element may be included in response to an SN-DATA TRANSMIT REQUEST or SN-RECONNECT PDU that contained more than one NSAPI. In combination with the "NSAPI" information element, it indicates to the MS those NSAPIs for which the MS's request has been accepted.   |        |      |       |                           |
| NOTE 4: The SwMI is not precluded from including the same NSAPI value in both the "NSAPI" information element and the "NSAPI for reconnection" information element. In the present document, the MS shall ignore a second incidence of the same NSAPI.   |        |      |       |                           |

#### 28.4.4.7 SN-DEACTIVATE PDP CONTEXT DEMAND

SN-DEACTIVATE PDP CONTEXT DEMAND PDU shall contain information elements as defined in table 28.32.

- Message: SN-DEACTIVATE PDP CONTEXT DEMAND PDU
- Response to: -
- Response expected: SN-DEACTIVATE PDP CONTEXT ACCEPT PDU
- Short description:

**Table 28.32: SN-DEACTIVATE PDP CONTEXT DEMAND PDU contents**

| Information element   | Length | Type | C/O/M | Remark                           |
|---|--------|------|-------|----------------------------------|
| SN PDU type   | 4      | 1    | M     | SN-DEACTIVATE PDP CONTEXT DEMAND |
| Deactivation type   | 8      | 1    | M     |                                  |
| NSAPI   | 4      |      | C     | see note 1                       |
| SNDCP network endpoint identifier   | 16     | 2    | O     | see note 2                       |
| Reserved  | 12     | 2    | O     | see note 3                       |
| NOTE 1: Shall be conditional on the value of the Deactivation type information element: <ul style="list-style-type: none"> <li>- when the value of the Deactivation type = 0 the NSAPI information element shall not be present;</li> <li>- when the value of the Deactivation type = 1 the NSAPI information element shall be present;</li> <li>- for all other values of the Deactivation type information element the NSAPI shall be present.</li> </ul> |        |      |       |                                  |
| NOTE 2: For usage, refer to clause 28.3.3.3.  |        |      |       |                                  |
| NOTE 3: Shall not be used in protocol defined in the present document.  |        |      |       |                                  |

### 28.4.4.8 SN-DEACTIVATE PDP CONTEXT ACCEPT

SN-DEACTIVATE PDP CONTEXT ACCEPT PDU shall contain information elements as defined in table 28.33.

- Message: SN-DEACTIVATE PDP CONTEXT ACCEPT PDU
- Response to: SN-DEACTIVATE PDP CONTEXT DEMAND PDU
- Response expected: -
- Short description: -

**Table 28.33: SN-DEACTIVATE PDP CONTEXT ACCEPT PDU contents**

| Information element   | Length | Type | C/O/M | Remark                           |
|---|--------|------|-------|----------------------------------|
| SN PDU type   | 4      | 1    | M     | SN-DEACTIVATE PDP CONTEXT ACCEPT |
| Deactivation type   | 8      | 1    | M     |                                  |
| NSAPI   | 4      |      | C     | see note 1                       |
| SND CP network endpoint identifier  | 16     | 2    | O     | see note 2                       |
| Reserved  | 11     | 2    | O     | see note 3                       |
| NOTE 1: Shall be conditional on the value of Deactivation type information element:<br>- when the Deactivation Type = 0 the NSAPI information element shall not be present;<br>- when the value of the Deactivation type = 1 the NSAPI information element shall be present;<br>- for all other values of the Deactivation type information element the NSAPI shall be present. |        |      |       |                                  |
| NOTE 2: For usage, refer to clause 28.3.3.3.  |        |      |       |                                  |
| NOTE 3: Shall not be used in protocol defined in the present document.  |        |      |       |                                  |

### 28.4.4.9 SN-END OF DATA

SN-END OF DATA PDU shall contain information elements as defined in table 28.34.

- Message: SN-END OF DATA PDU
- Response to: -/SN-END OF DATA PDU
- Response expected: -/SN-END OF DATA PDU
- Short description: -

**Table 28.34: SN-END OF DATA PDU contents**

| Information element  | Length | Type | C/O/M | Remark         |
|--|--------|------|-------|----------------|
| SN PDU type  | 4      | 1    | M     | SN-END OF DATA |
| Immediate service change   | 1      | 1    | M     |                |
| Reserved   | 41     | 2    | O     | see note       |
| NOTE: Shall not be used in protocol defined in the present document. |        |      |       |                |

### 28.4.4.9a SN-MODIFY PDP CONTEXT REQUEST

SN-MODIFY PDP CONTEXT REQUEST PDU shall contain information elements as defined in table 28.35.

- Message: SN-MODIFY PDP CONTEXT REQUEST PDU
- Response to: -
- Response expected: SN-MODIFY PDP CONTEXT RESPONSE PDU
- Short description: -

**Table 28.35: SN-MODIFY PDP CONTEXT REQUEST PDU contents**

| Information element | Length | Type | C/O/M | Remark                        |
|---------------------|--------|------|-------|-------------------------------|
| SN PDU type         | 4      | 1    | M     | SN-MODIFY                     |
| Modify sub-type     | 4      | 1    | M     | SN-MODIFY PDP CONTEXT REQUEST |
| NSAPI               | 4      | 1    | M     |                               |
| QoS                 | varies | 1    | M     |                               |

### 28.4.4.9b SN-MODIFY PDP CONTEXT RESPONSE

SN-MODIFY PDP CONTEXT RESPONSE PDU shall contain information elements as defined in table 28.36.

- Message: SN-MODIFY PDP CONTEXT RESPONSE PDU
- Response to: SN-MODIFY PDP CONTEXT REQUEST PDU
- Response expected: -
- Short description: -

**Table 28.36: SN-MODIFY PDP CONTEXT RESPONSE PDU contents**

| Information element   | Length | Type | C/O/M | Remark                          |
|---|--------|------|-------|---------------------------------|
| SN PDU type   | 4      | 1    | M     | SN-MODIFY                       |
| Modify sub-type   | 4      | 1    | M     | SN-MODIFY PDP CONTEXT RESPONSE. |
| NSAPI   | 4      | 1    | M     |                                 |
| Modification result   | 1      | 1    | M     | see note 1                      |
| Modification reject cause   | 8      |      | C     | see note 2                      |
| PDU priority max  | 3      |      | C     | see note 3                      |
| QoS   | varies |      | C     | see note 3                      |
| NOTE 1: "Modification rejected" means the PDP context remains unaltered.                      |        |      |       |                                 |
| NOTE 2: Shall be present only if "modification result" has value "1" (modification rejected). |        |      |       |                                 |
| NOTE 3: Shall be present only if "modification result" has value "0" (modification applied).  |        |      |       |                                 |

### 28.4.4.9c SN-MODIFY PDP CONTEXT AVAILABILITY

SN-MODIFY PDP CONTEXT AVAILABILITY PDU shall contain information elements as defined in table 28.37.

- Message: SN-MODIFY PDP CONTEXT AVAILABILITY PDU
- Response to: -
- Response expected: -
- Short description: -

**Table 28.37: SN-MODIFY PDP CONTEXT AVAILABILITY PDU contents**

| PDP context availability | 3      | 1    | M     |                                    |

### 28.4.4.9d SN-MODIFY PDP CONTEXT USAGE

SN-MODIFY PDP CONTEXT USAGE PDU shall contain information elements as defined in table 28.38.

- Message: SN-MODIFY PDP CONTEXT USAGE PDU
- Response to: -
- Response expected: -
- Short description: -

**Table 28.38: SN-MODIFY PDP CONTEXT USAGE PDU contents**

| Information element | Length | Type | C/O/M | Remark                                     |
|---------------------|--------|------|-------|--|
| SN PDU type         | 4      | 1    | M     | SN-MODIFY                                  |
| Modify sub-type     | 4      | 1    | M     | SN-MODIFY PDP CONTEXT USAGE.               |
| NSAPI               | 4      | 1    | M     |  |
| PDP context usage   | 3      | 1    | M     |  |
| Reserved            | 9      | 2    | O     | Shall not be used in the present document. |

NOTE: This PDU is an exact fit in SCH-Q/RA when the reserved type 2 information element is included with an SSI and without a layer 2 reservation requirement.

### 28.4.4.10 SN-NOT SUPPORTED

SN-NOT SUPPORTED PDU shall contain information elements as defined in table 28.39.

- Message: SN-NOT SUPPORTED PDU
- Response to: Any individually addressed SN PDU
- Response expected: -
- Short description: This PDU may be sent by the MS or the SwMI to indicate that the received SN PDU or the function indicated in the PDU is not supported by the peer entity.

**Table 28.39: SN-NOT SUPPORTED PDU contents**

| Information element       | Length | Type | C/O/M | Remark           |
|---------------------------|--------|------|-------|------------------|
| SN PDU type               | 4      | 1    | M     | SN-NOT SUPPORTED |
| Not supported SN PDU type | 4      | 1    | M     |                  |

### 28.4.4.11 SN-PAGE REQUEST

SN-PAGE REQUEST PDU shall contain information elements as defined in table 28.40.

- Message: SN-PAGE REQUEST PDU
- Response to: -
- Response expected: No response or SN-PAGE RESPONSE PDU
- Short description: -

**Table 28.40: SN-PAGE REQUEST PDU contents**

| Information element                        | Length | Type | C/O/M | Remark          |
|--|--------|------|-------|-----------------|
| SN PDU type                                | 4      | 1    | M     | SN-PAGE REQUEST |
| NSAPI                                      | 4      | 1    | M     |                 |
| Reply requested                            | 1      | 1    | M     |                 |
| SNDCP network endpoint identifier          | 16     | 2    | O     | see note        |
| NOTE: For usage, refer to clause 28.3.3.3. |        |      |       |                 |

### 28.4.4.12 SN-PAGE RESPONSE

SN-PAGE RESPONSE PDU shall contain information elements as defined in table 28.41.

- Message: SN-PAGE RESPONSE PDU
- Response to: SN-PAGE REQUEST PDU
- Response expected: -
- Short description: -

**Table 28.41: SN-PAGE RESPONSE PDU contents**

| Information element  | Length | Type | C/O/M | Remark           |
|--|--------|------|-------|------------------|
| SN PDU type  | 4      | 1    | M     | SN-PAGE RESPONSE |
| NSAPI  | 4      | 1    | M     |                  |
| PD service status  | 1      | 1    | M     |                  |
| Logical link status  | 1      | 1    | M     |                  |
| Enhanced $\pi/4$ -DQPSK service (see note 4)   | 1      | 1    | M     |                  |
| Resource request   | varies |      | C     | See note 1       |
| SNDCP network endpoint identifier  | 16     | 2    | O     | See note 2       |
| Reserved   | 18     | 2    | O     | See note 3       |
| NOTE 1: For usage, refer to clause 28.3.5.2a. Shall be conditional on the value of Enhanced $\pi/4$ -DQPSK service information element: <ul style="list-style-type: none"> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 1 the Resource request information element shall be present;</li> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 0 the Resource request information element shall not be present.</li> </ul> |        |      |       |                  |
| NOTE 2: For usage, refer to clause 28.3.3.3.   |        |      |       |                  |
| NOTE 3: Shall not be used in protocol defined in the present document.   |        |      |       |                  |
| NOTE 4: This was formerly known as the "enhanced service" information element.   |        |      |       |                  |

If the MS supports the use of non-conforming PDCHs, the "channel advice flag" parameter in the MLE-UNITDATA request primitive containing this PDU should be set to "channel advice requested".

### 28.4.4.13 SN-RECONNECT

SN-RECONNECT PDU shall contain information elements as defined in table 28.42.

- Message: SN-RECONNECT PDU
- Response to: -
- Response expected: No response, SN-DATA TRANSMIT RESPONSE PDU or SN-DATA TRANSMIT REQUEST PDU
- Short description: -

**Table 28.42: SN-RECONNECT PDU contents**

| Information element   | Length | Type | C/O/M | Remark            |
|---|--------|------|-------|-------------------|
| SN PDU type   | 4      | 1    | M     | SN-RECONNECT      |
| Data to send  | 1      | 1    | M     | See note 8        |
| NSAPI   | 4      |      | C     | See note 1        |
| Enhanced $\pi/4$ -DQPSK service (see note 5)  | 1      | 1    | M     |                   |
| Resource request  | varies |      | C     | See note 2        |
| SNDCP network endpoint identifier   | 16     | 2    | O     | See note 3        |
| Reserved  | 19     | 2    | O     | See note 4        |
| NSAPI for reconnection  | varies | 4    | O     | See notes 6 and 7 |
| <p>NOTE 1: Shall be conditional on the value of the Data to send information element:</p> <ul style="list-style-type: none"> <li>- when Data to send = 1 the NSAPI information element shall be present;</li> <li>- when Data to send = 0 the NSAPI information element shall not be present.</li> </ul> <p>NOTE 2: For usage, refer to clause 28.3.5.2a. Shall be conditional on the value of the Enhanced <math>\pi/4</math>-DQPSK service information element:</p> <ul style="list-style-type: none"> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 1 the Resource request information element shall be present;</li> <li>- when the Enhanced <math>\pi/4</math>-DQPSK service = 0 the Resource request information element shall not be present.</li> </ul> <p>NOTE 3: For usage, refer to clause 28.3.3.3.</p> <p>NOTE 4: Shall not be used in protocol defined in the present document.</p> <p>NOTE 5: This was formerly known as the "enhanced service" information element.</p> <p>NOTE 6: This information element may be included if the MS wishes to request reconnection for more than one NSAPI. In combination with the "NSAPI" information element, it indicates to the SwMI those NSAPIs for which the MS wishes reconnection.</p> <p>NOTE 7: The MS is not precluded from including the same NSAPI in both the "NSAPI" information element and the "NSAPI for reconnection" information element. In the present document, the SwMI shall ignore a second incidence of the same NSAPI.</p> <p>NOTE 8: The MS is not precluded from setting "data to send" if it wishes to be on a PDCH because it expects imminent reception of data on the downlink or imminent arrival of data for transmission on the uplink.</p> |        |      |       |                   |

If the MS supports the use of non-conforming PDCHs, the "channel advice flag" parameter in the MLE-UNITDATA request primitive containing this PDU should be set to "channel advice requested".

### 28.4.4.14 SN-UNITDATA

SN-UNITDATA PDU shall contain information elements as defined in table 28.43.

- Message: SN-UNITDATA PDU
- Response to: -
- Response expected: -
- Short description: SN-UNITDATA PDU is used for unacknowledged service.

**Table 28.43: SN-UNITDATA PDU contents**

| Information element | Length   | Type | C/O/M | Remark      |
|---------------------|--|------|-------|-------------|
| SN PDU type         | 4  | 1    | M     | SN-UNITDATA |
| NSAPI               | 4  | 1    | M     |             |
| PCOMP               | 4  | 1    | M     |             |
| DCOMP               | 4  | 1    | M     |             |
| N-PDU               | varies   | 1    | M     |             |
| NOTE:               | The N-PDU length is defined by the length of the lower layer PDU. There shall be no O-bit after the N-PDU. |      |       |             |

### 28.4.5 SNDCP information elements coding

#### 28.4.5.1 Accept/Reject

The Accept/Reject information element shall be encoded as defined in table 28.44.

**Table 28.44: Accept/Reject information element contents**

| Information element | Length | Value | Remark                       |
|---------------------|--------|-------|------------------------------|
| Accept/Reject       | 1      | 0     | Request rejected by the SwMI |
|                     |        | 1     | Request accepted by the SwMI |

#### 28.4.5.2 Access point name index

The Access point name index information element shall be encoded as defined in table 28.45.

**Table 28.45: Access point name index information element contents**

| Information element     | Length | Value | Remark |
|-------------------------|--------|-------|--------|
| Access point name index | 16     | any   |        |

### 28.4.5.3 Activation reject cause

The Activation reject cause information element shall be encoded as defined in table 28.46.

**Table 28.46: Activation reject cause information element contents**

| Information element | Length   | Value | Remark   |
|---------------------|----------|-------|--|
| Reject cause        | 8        | 0     | Undefined  |
|                     |          | 1     | MS not provisioned for Packet Data                     |
|                     |          | 2     | IPv4 not supported                                     |
|                     |          | 3     | IPv6 not supported                                     |
|                     |          | 4     | IPv4 dynamic address negotiation not supported         |
|                     |          | 5     | IPv6 stateful address autoconfiguration not supported  |
|                     |          | 6     | IPv6 stateless address autoconfiguration not supported |
|                     |          | 7     | Dynamic address pool empty                             |
|                     |          | 8     | Static address not correct                             |
|                     |          | 9     | Static address in use                                  |
|                     |          | 10    | Static address not allowed                             |
|                     |          | 11    | Static IP address congestion                           |
|                     |          | 12    | TETRA Packet data not supported on this location area  |
|                     |          | 13    | TETRA Packet data not supported on this network.       |
|                     |          | 14    | Temporary rejection                                    |
|                     |          | 15    | Packet Data MS Type not supported                      |
|                     |          | 16    | SNDTCP version not supported                           |
|                     |          | 17    | Mobile IPv4 not supported                              |
|                     |          | 18    | Mobile IPv4 Co-located care of address not supported   |
|                     |          | 19    | Maximum number of PDP Contexts per ITSI exceeded       |
|                     |          | 20    | User authentication failed                             |
|                     |          | 21    | Activation rejected by external PDN                    |
|                     |          | 22    | Access point name index not correct                    |
|                     |          | 23    | Requested minimum peak throughput not available        |
|                     |          | 24    | Scheduled access not supported                         |
|                     |          | 25    | Requested schedule not available                       |
|                     |          | 26    | Requested QoS not available                            |
|                     |          | 27    | Secondary PDP contexts not supported                   |
|                     |          | 28    | Primary PDP context does not exist                     |
|                     |          | 29    | Asymmetric QoS not supported                           |
|                     |          | 30    | Automatic QoS filter not supported                     |
|                     |          | 31    | Specified QoS filter not supported                     |
|                     |          | 32    | QoS filter type not supported                          |
|                     |          | 33    | QoS filter not available for primary PDP context       |
|                     |          | 34    | SNDTCP service temporarily not available               |
| others              | Reserved |       |  |

### 28.4.5.3a Additional QoS information A

The "additional QoS information A" information element shall be encoded as defined in table 28.47.

**Table 28.47: Additional QoS information A information element contents**

| Information element          | Length | Value | Remark   |
|------------------------------|--------|-------|----------|
| Additional QoS information A | 16     | any   | Reserved |

### 28.4.5.3b Additional QoS information A included

The "additional QoS information A included" information element shall be encoded as defined in table 28.48.

**Table 28.48: Additional QoS information A included information element contents**

| Information element                   | Length | Value | Remark       |
|---------------------------------------|--------|-------|--------------|
| Additional QoS information A included | 1      | 0     | Not included |
|                                       |        | 1     | Included     |

### 28.4.5.3c Additional QoS information B

The "additional QoS information B" information element shall be encoded as defined in table 28.49.

**Table 28.49: Additional QoS information B information element contents**

| Information element          | Length | Value | Remark   |
|------------------------------|--------|-------|----------|
| Additional QoS information B | 16     | any   | Reserved |

### 28.4.5.3d Additional QoS information B included

The "additional QoS information B included" information element shall be encoded as defined in table 28.50.

**Table 28.50: Additional QoS information B included information element contents**

| Information element                   | Length | Value | Remark       |
|---------------------------------------|--------|-------|--------------|
| Additional QoS information B included | 1      | 0     | Not included |
|                                       |        | 1     | Included     |

### 28.4.5.4 Address Type Identifier in Demand

The Address Type Identifier in Demand information element shall be encoded as defined in table 28.51.

**Table 28.51: Address Type Identifier in Demand information element contents**

| Information element               | Length | Value  | Remark  |
|-----------------------------------|--------|--------|---|
| Address Type Identifier in Demand | 3      | 0      | IPv4 Static Address                                 |
|                                   |        | 1      | IPv4 Dynamic Address Negotiation                    |
|                                   |        | 2      | IPv6  |
|                                   |        | 3      | Mobile IPv4 Foreign Agent care of address requested |
|                                   |        | 4      | Mobile IPv4 Co-located care-of address requested    |
|                                   |        | 5      | Primary NSAPI (secondary PDP context requested)     |
|                                   |        | others | Reserved  |

### 28.4.5.4a Asymmetrical QoS

The asymmetrical QoS information element shall be encoded as defined in table 28.52.

**Table 28.52: Asymmetrical QoS information element contents**

| Information element | Length | Value | Remark   |
|---------------------|--------|-------|--|
| Asymmetrical QoS    | 1      | 0     | Symmetrical QoS  |
|                     |        | 1     | Asymmetrical QoS (separate uplink QoS and downlink QoS included) |

### 28.4.5.4b Background class request

The background class request information element shall be encoded as defined in table 28.53.

**Table 28.53: Background class request information element contents**

| Information element      | Length | Value | Remark           |
|--------------------------|--------|-------|------------------|
| Background class request | 1      | 0     | Background class |
|                          |        | 1     | Any data class   |

### 28.4.5.5 BSD data compression parameters

The BSD data compression parameters information element shall be encoded as defined in table 28.54.

**Table 28.54: BSD data compression parameters information element contents**

| Information element     | Length | Type | C/O/M | Remark |
|-------------------------|--------|------|-------|--------|
| BSD compression version | 3      | 1    | M     |        |
| BSD dictionary size     | 5      | 1    | M     |        |

### 28.4.5.6 BSD compression version

The BSD compression version information element shall be encoded as defined in table 28.55.

**Table 28.55: BSD compression version information element contents**

| Information element     | Length | Value  | Remark    |
|-------------------------|--------|--------|-----------|
| BSD compression version | 3      | 0      | Reserved  |
|                         |        | 1      | Version 1 |
|                         |        | 2 to 7 | Reserved  |

### 28.4.5.7 BSD dictionary size

The BSD dictionary size information element shall be encoded as defined in table 28.56.

**Table 28.56: BSD dictionary size information element contents**

| Information element | Length | Value    | Remark                         |
|---------------------|--------|----------|--------------------------------|
| BSD dictionary size | 5      | 0 to 8   | Reserved                       |
|                     |        | 9 to 16  | Length of largest code in bits |
|                     |        | 17 to 31 | Reserved                       |

## 28.4.5.7a CONTEXT\_READY timer

The CONTEXT\_READY timer information element shall be encoded as defined in table 28.57.

**Table 28.57: CONTEXT\_READY timer information element contents**

| Information element | Length   | Value | Remark                |
|---------------------|----------|-------|-----------------------|
| CONTEXT_READY timer | 4        | 0     | Track the READY timer |
|                     |          | 1     | 200 ms                |
|                     |          | 2     | 500 ms                |
|                     |          | 3     | 700 ms                |
|                     |          | 4     | 1 s                   |
|                     |          | 5     | 2 s                   |
|                     |          | 6     | 3 s                   |
|                     |          | 7     | 5 s                   |
|                     |          | 8     | 10 s                  |
|                     |          | 9     | 20 s                  |
|                     |          | 10    | 30 s                  |
|                     |          | 11    | 60 s                  |
|                     |          | 12    | 120 s                 |
|                     |          | 13    | 180 s                 |
|                     |          | 14    | 300 s                 |
| 15                  | Reserved |       |                       |

## 28.4.5.7b Data class

The Data class information element shall be encoded as defined in table 28.58.

**Table 28.58: Data class information element contents**

| Information element | Length | Value | Remark     |
|---------------------|--------|-------|------------|
| Data class          | 3      | 0     | Background |
|                     |        | 1     | Telemetry  |
|                     |        | 2     | Real-time  |
|                     |        | 3     | Reserved   |
|                     |        | 4     | Reserved   |
|                     |        | 5     | Reserved   |
|                     |        | 6     | Reserved   |
|                     |        | 7     | Reserved   |

## 28.4.5.7c Data priority details

The Data priority details information element shall be encoded as defined in table 28.59.

**Table 28.59: Data priority details information element contents**

| Information element                      | Length | Type | C/O/M | Remark               |
|--|--------|------|-------|----------------------|
| Network default data priority            | 3      | 1    | M     |                      |
| Layer 2 data priority lifetime           | 6      | 1    | M     |                      |
| Layer 2 data priority signalling delay   | 3      | 1    | M     |                      |
| Data priority random access delay factor | 3      | 1    | M     |                      |
| Reserved                                 | 9      | 1    | M     | Shall be set to "0". |

NOTE: The layer 2 data priority lifetime should normally be set to a greater time than the layer 2 data priority signalling delay.

### 28.4.5.7d Data priority random access delay factor

The Data priority random access delay factor information element shall be encoded as defined in table 28.60.

**Table 28.60: Data priority random access delay factor information element contents**

| Information element                      | Length | Value | Remark                                       |
|--|--------|-------|--|
| Data priority random access delay factor | 3      | 0     | Data priority random access delay factor = 0 |
|  |        | 1     | Data priority random access delay factor = 1 |
|  |        | etc.  | etc.   |
|  |        | 7     | Data priority random access delay factor = 7 |

NOTE: The use of the data priority random access delay factor is defined in clauses 23.4.7.5.2 and 23.4.7.5.3.

### 28.4.5.7e Data priority request result

The Data priority request result information element shall be encoded as defined in table 28.61.

**Table 28.61: Data priority request result information element contents**

| Information element   | Length | Value | Remark                      |
|---|--------|-------|-----------------------------|
| Data priority request result  | 1      | 0     | Request accepted (see note) |
|   |        | 1     | Request rejected            |
| NOTE: This means that the MS default data priority has been changed, but it need not be changed to the value requested by the MS. |        |       |                             |

### 28.4.5.7f Data priority request type

The Data priority request type information element shall be encoded as defined in table 28.62.

**Table 28.62: Data priority request type information element contents**

| Information element        | Length | Value | Remark  |
|----------------------------|--------|-------|---|
| Data priority request type | 4      | 0     | Set MS default data priority 0                                      |
|                            |        | 1     | Set MS default data priority 1                                      |
|                            |        | etc.  | etc.  |
|                            |        | 7     | Set MS default data priority 7                                      |
|                            |        | 8     | Set MS default data priority to track network default data priority |
|                            |        | 9     | Report Network and MS default data priorities                       |
|                            |        | 10    | Reserved  |
|                            |        | etc.  | etc.  |
|                            |        | 15    | Reserved  |

### 28.4.5.7g Data priority sub-type

The data priority sub-type information element shall be encoded as defined in table 28.63.

**Table 28.63: Data priority sub-type information element contents**

| Information element    | Length | Value | Remark                           |
|------------------------|--------|-------|----------------------------------|
| Data priority sub-type | 4      | 0     | SN-DATA-PRIORITY ACKNOWLEDGEMENT |
|                        |        | 1     | SN-DATA-PRIORITY INFORMATION     |
|                        |        | 2     | SN-DATA-PRIORITY REQUEST         |
|                        |        | 3     | Reserved                         |
|                        |        | etc.  | etc.                             |
|                        |        | 15    | Reserved                         |

### 28.4.5.8 Data to send

The Data to send information element shall be encoded as defined in table 28.64.

**Table 28.64: Data to Send information element contents**

| Information element | Length | Value | Remark   |
|---------------------|--------|-------|--|
| Data to send        | 1      | 0     | No data to send  |
|                     |        | 1     | SN-DATA PDU or SN-UNITDATA PDU awaiting transmission on uplink |

### 28.4.5.8a Delay class

The Delay class information element shall be encoded as defined in table 28.65.

**Table 28.65: Delay class information element contents**

| Information element                             | Length | Value | Remark        |
|---|--------|-------|---------------|
| Delay class (see note)                          | 2      | 0     | Low           |
|   |        | 1     | Moderate      |
|   |        | 2     | High          |
|   |        | 3     | Unpredictable |
| NOTE: Delay classes are defined in table 28.10. |        |       |               |

### 28.4.5.9 DCOMP

The DCOMP information element shall be encoded as defined in table 28.66.

**Table 28.66: DCOMP information element contents**

| Information element | Length | Value  | Remark   |
|---------------------|--------|--------|--|
| DCOMP               | 4      | 0      | No compression   |
|                     |        | 1      | Recommendation ITU-T V.42bis [27]  |
|                     |        | 2      | BSD compression  |
|                     |        | 3      | Predictor compression  |
|                     |        | 4      | BSD uncompressible packet  |
|                     |        | Others | Reserved for further compression algorithms(a list of fixed or negotiated algorithms e.g. pzip, fax, MPEG) |

### 28.4.5.10 DCOMP negotiation

The DCOMP negotiation information element shall be encoded as defined in table 28.67.

**Table 28.67: DCOMP negotiation information element contents**

| Information element   | Length | Type | C/O/M | Remark   |
|---|--------|------|-------|----------|
| DCOMP   | 4      | 1    | M     |          |
| Data compression parameters   | varies |      | C     | see note |
| NOTE: Shall be conditional on the value of DCOMP:   |        |      |       |          |
| - when DCOMP = 0, 3 or 4 no data compression parameters are present;                                  |        |      |       |          |
| - when DCOMP = 1, "Recommendation ITU-T 4.2bis data compression request parameters" shall be present; |        |      |       |          |
| - when DCOMP = 2, "BSD data compression parameters" shall be present.                                 |        |      |       |          |

### 28.4.5.11 Deactivation type

The Deactivation type information element shall be encoded as defined in table 28.68.

**Table 28.68: Deactivation type information element contents**

| Information element | Length | Value  | Remark                            |
|---------------------|--------|--------|-----------------------------------|
| Deactivation type   | 8      | 0      | Deactivate all NSAPIs             |
|                     |        | 1      | Deactivate NSAPI given in the PDU |
|                     |        | others | Reserved                          |

### 28.4.5.11a Diffserv filter

The Diffserv filter information element shall be encoded as defined in table 28.69.

**Table 28.69: Diffserv filter information element contents**

| Information element  | Length | Type | C/O/M | Remark     |
|--|--------|------|-------|------------|
| DSCP   | 8      |      | M     | See note 1 |
| Reserved   | 8      |      | M     | See note 2 |
| NOTE 1: Contains a differentiated services code point value (see IETF RFC 2474 [43] and IETF RFC 2475 [44]). |        |      |       |            |
| NOTE 2: Shall be set to zero in the present document.  |        |      |       |            |

### 28.4.5.12 Enhanced $\pi/4$ -DQPSK service

The Enhanced  $\pi/4$ -DQPSK service information element shall be encoded as defined in table 28.70.

**Table 28.70: Enhanced  $\pi/4$ -DQPSK service information element contents**

| Information element             | Length | Value | Remark  |
|---------------------------------|--------|-------|---|
| Enhanced $\pi/4$ -DQPSK service | 1      | 0     | Enhanced $\pi/4$ -DQPSK service not requested |
|                                 |        | 1     | Enhanced $\pi/4$ -DQPSK service requested     |

NOTE: This was formerly known as the "enhanced service" information element.

### 28.4.5.13 Immediate service change

The Immediate service change information element shall be encoded in table 28.71.

**Table 28.71: Immediate service change information element contents**

| Information element      | Length | Value | Remark        |
|--------------------------|--------|-------|---------------|
| Immediate service change | 1      | 0     | Not indicated |
|                          |        | 1     | Indicated     |

### 28.4.5.14 IP address ipv4

The IP address ipv4 information element shall be encoded as defined in table 28.72.

**Table 28.72: IP address IPv4 information element contents**

| Information element | Length | Value | Remark |
|---------------------|--------|-------|--------|
| IP address ipv4     | 32     | any   |        |

### 28.4.5.15 Largest header size in octets that may be compressed

The Largest header size in octets that may be compressed information element shall be encoded as defined in table 28.73.

**Table 28.73: Largest header size in octets that may be compressed information element contents**

| Information element                             | Length | Value    | Remark                                    |
|---|--------|----------|---|
| Largest header in octets that may be compressed | 8      | 0 to 255 | The size of the largest header in octets. |

### 28.4.5.15a Layer 2 data priority lifetime

The Layer 2 data priority lifetime information element shall be encoded as defined in table 28.74.

**Table 28.74: Layer 2 data priority lifetime information element contents**

| Information element            | Length | Value | Remark         |
|--------------------------------|--------|-------|----------------|
| Layer 2 data priority lifetime | 6      | 0     | Reserved       |
|                                |        | 1     | 2 multiframe   |
|                                |        | 2     | 4 multiframe   |
|                                |        | etc.  | etc.           |
|                                |        | 63    | 126 multiframe |

### 28.4.5.15b Layer 2 data priority signalling delay

The Layer 2 data priority signalling delay information element shall be encoded as defined in table 28.75.

**Table 28.75: Layer 2 data priority signalling delay information element contents**

| Information element                    | Length | Value | Remark         |
|--|--------|-------|----------------|
| Layer 2 data priority signalling delay | 3      | 0     | 6 TDMA frames  |
|  |        | 1     | 9 TDMA frames  |
|  |        | 2     | 12 TDMA frames |
|  |        | 3     | 18 TDMA frames |
|  |        | 4     | 27 TDMA frames |
|  |        | 5     | 36 TDMA frames |
|  |        | 6     | 54 TDMA frames |
|  |        | 7     | 90 TDMA frames |

### 28.4.5.16 Logical link status

The Logical link status information element shall be encoded as defined in table 28.76.

**Table 28.76: Logical link status information element contents**

| Information element | Length | Value | Remark                      |
|---------------------|--------|-------|-----------------------------|
| Logical link status | 1      | 0     | Advanced link not connected |
|                     |        | 1     | Advanced link connected     |

### 28.4.5.17 Maximum interval between full headers

The Maximum interval between full headers indicates the maximum number of compressed non-TCP headers that can be sent between full headers. The information element shall be encoded as defined in table 28.77.

**Table 28.77: Maximum interval between full headers information element contents**

| Information element                   | Length | Value    | Remark   |
|---------------------------------------|--------|----------|--|
| Maximum interval between full headers | 8      | 0        | There is no limit to the number of consecutive compressed headers. |
|                                       |        | 1 to 255 | Maximum 16 × value consecutive compressed headers.                 |

### 28.4.5.18 Maximum time interval between full headers

The Maximum time interval between full headers indicates the maximum interval between full headers. The information element shall be encoded as defined in table 28.78.

**Table 28.78: Maximum time interval between full headers information element contents**

| Information element                        | Length | Value    | Remark   |
|--|--------|----------|--|
| Maximum time interval between full headers | 8      | 0        | Infinity.  |
|  |        | 1 to 255 | Compressed headers may not be sent more than 5 × value s after sending the last full header. |

### 28.4.5.19 Maximum transmission unit

The Maximum transmission unit information element shall be encoded as defined in table 28.79.

**Table 28.79: Maximum Transmission Unit information element contents**

| Information element       | Length | Value | Remark       |
|---------------------------|--------|-------|--------------|
| Maximum transmission unit | 3      | 0     | Reserved     |
|                           |        | 1     | 296 octets   |
|                           |        | 2     | 576 octets   |
|                           |        | 3     | 1 006 octets |
|                           |        | 4     | 1 500 octets |
|                           |        | 5     | 2 002 octets |
|                           |        | 6     | Reserved     |
|                           |        | 7     | Reserved     |

## 28.4.5.19a Mean active throughput

The Mean active throughput information element shall be encoded as defined in table 28.80.

**Table 28.80: Mean active throughput information element contents**

| Information element    | Length | Value | Remark                          |
|------------------------|--------|-------|---------------------------------|
| Mean active throughput | 4      | 0     | No value given                  |
|                        |        | 1     | < 1 000 octets s <sup>-1</sup>  |
|                        |        | 2     | ≥ 1 000 octets s <sup>-1</sup>  |
|                        |        | 3     | ≥ 2 000 octets s <sup>-1</sup>  |
|                        |        | 4     | ≥ 4 000 octets s <sup>-1</sup>  |
|                        |        | 5     | ≥ 8 000 octets s <sup>-1</sup>  |
|                        |        | 6     | ≥ 16 000 octets s <sup>-1</sup> |
|                        |        | 7     | ≥ 32 000 octets s <sup>-1</sup> |
|                        |        | 8     | ≥ 64 000 octets s <sup>-1</sup> |
|                        |        | 9     | Reserved                        |
|                        |        | etc.  | etc.                            |
|                        |        | 15    | Reserved                        |

## 28.4.5.19b Mean throughput

The Mean throughput information element shall be encoded as defined in table 28.81.

**Table 28.81: Mean throughput information element contents**

| Information element | Length       | Value | Remark                            |
|---------------------|--------------|-------|-----------------------------------|
| Mean throughput     | 5            | 0     | No value given                    |
|                     |              | 1     | 100 octets h <sup>-1</sup>        |
|                     |              | 2     | 200 octets h <sup>-1</sup>        |
|                     |              | 3     | 500 octets h <sup>-1</sup>        |
|                     |              | 4     | 1 000 octets h <sup>-1</sup>      |
|                     |              | 5     | 2 000 octets h <sup>-1</sup>      |
|                     |              | 6     | 5 000 octets h <sup>-1</sup>      |
|                     |              | 7     | 10 000 octets h <sup>-1</sup>     |
|                     |              | 8     | 20 000 octets h <sup>-1</sup>     |
|                     |              | 9     | 50 000 octets h <sup>-1</sup>     |
|                     |              | 10    | 100 000 octets h <sup>-1</sup>    |
|                     |              | 11    | 200 000 octets h <sup>-1</sup>    |
|                     |              | 12    | 500 000 octets h <sup>-1</sup>    |
|                     |              | 13    | 1 000 000 octets h <sup>-1</sup>  |
|                     |              | 14    | 2 000 000 octets h <sup>-1</sup>  |
|                     |              | 15    | 5 000 000 octets h <sup>-1</sup>  |
|                     |              | 16    | 10 000 000 octets h <sup>-1</sup> |
|                     |              | 17    | 20 000 000 octets h <sup>-1</sup> |
|                     |              | 18    | 50 000 000 octets h <sup>-1</sup> |
|                     |              | 19    | Reserved                          |
|                     |              | etc.  | etc.                              |
| 30                  | Reserved     |       |                                   |
| 31                  | Best effort. |       |                                   |

## 28.4.5.19c Minimum peak throughput

The Minimum peak throughput information element shall be encoded as defined in table 28.82.

**Table 28.82: Minimum peak throughput information element contents**

| Information element     | Length   | Value | Remark                          |
|-------------------------|----------|-------|---------------------------------|
| Minimum peak throughput | 4        | 0     | No value given                  |
|                         |          | 1     | < 1 000 octets s <sup>-1</sup>  |
|                         |          | 2     | ≥ 1 000 octets s <sup>-1</sup>  |
|                         |          | 3     | ≥ 2 000 octets s <sup>-1</sup>  |
|                         |          | 4     | ≥ 4 000 octets s <sup>-1</sup>  |
|                         |          | 5     | ≥ 8 000 octets s <sup>-1</sup>  |
|                         |          | 6     | ≥ 16 000 octets s <sup>-1</sup> |
|                         |          | 7     | ≥ 32 000 octets s <sup>-1</sup> |
|                         |          | 8     | ≥ 64 000 octets s <sup>-1</sup> |
|                         |          | 9     | Reserved                        |
|                         |          | etc.  | etc.                            |
| 15                      | Reserved |       |                                 |

## 28.4.5.19d Modification reject cause

The modification reject cause information element shall be encoded as defined in table 28.83.

**Table 28.83: Modification reject cause information element contents**

| Information element       | Length | Value  | Remark   |
|---------------------------|--------|--------|--|
| Modification reject cause | 8      | 0      | Undefined  |
|                           |        | 14     | Temporary rejection                              |
|                           |        | 23     | Requested minimum peak throughput not available  |
|                           |        | 24     | Scheduled access not supported                   |
|                           |        | 25     | Requested schedule not available                 |
|                           |        | 26     | Requested QoS not available                      |
|                           |        | 27     | Secondary PDP contexts not supported             |
|                           |        | 28     | Primary PDP context does not exist               |
|                           |        | 29     | Asymmetric QoS not supported                     |
|                           |        | 30     | Automatic QoS filter not supported               |
|                           |        | 31     | Specified QoS filter not supported               |
|                           |        | 32     | QoS filter type not supported                    |
|                           |        | 33     | QoS filter not available for primary PDP context |
|                           |        | 34     | SNDP service temporarily not available           |
|                           |        | others | Reserved   |

## 28.4.5.19e Modification result

The modification result information element shall be encoded as defined in table 28.84.

**Table 28.84: Modification result information element contents**

| Information element | Length | Value | Remark   |
|---------------------|--------|-------|--|
| Modification result | 1      | 0     | Modification applied                                   |
|                     |        | 1     | Modification rejected (PDP context remains unmodified) |

## 28.4.5.19f Modify sub-type

The modify sub-type information element shall be encoded as defined in table 28.85.

**Table 28.85: Modify sub-type information element contents**

| Information element | Length | Value | Remark                             |
|---------------------|--------|-------|------------------------------------|
| Modify sub-type     | 4      | 0     | SN-MODIFY PDP CONTEXT REQUEST      |
|                     |        | 1     | SN-MODIFY PDP CONTEXT RESPONSE     |
|                     |        | 3     | SN-MODIFY PDP CONTEXT AVAILABILITY |
|                     |        | 4     | SN-MODIFY PDP CONTEXT USAGE        |
|                     |        | etc.  | etc.                               |
|                     |        | 15    | Reserved                           |

## 28.4.5.19g MS default data priority

The MS default data priority information element shall be encoded as defined in table 28.86.

**Table 28.86: MS default data priority information element contents**

| Information element      | Length | Value | Remark  |
|--------------------------|--------|-------|---|
| MS default data priority | 4      | 0     | MS default data priority = 0  |
|                          |        | 1     | MS default data priority = 1  |
|                          |        | etc.  | etc.  |
|                          |        | 7     | MS default data priority = 7  |
|                          |        | 8     | MS default data priority = Network default data priority (see note) |
|                          |        | 9     | Reserved  |
|                          |        | etc.  | etc.  |
|                          |        | 15    | Reserved  |

NOTE: When this value is set, the MS default data priority tracks the value of the network default data priority.

## 28.4.5.19h MS default data priority flag

The MS default data priority flag information element shall be encoded as defined in table 28.87.

**Table 28.87: MS default data priority flag information element contents**

| Information element           | Length | Value | Remark                                |
|-------------------------------|--------|-------|---------------------------------------|
| MS default data priority flag | 1      | 0     | MS default data priority not included |
|                               |        | 1     | MS default data priority included     |

## 28.4.5.19i Network default data priority

The Network default data priority information element shall be encoded as defined in table 28.88.

**Table 28.88: Network default data priority information element contents**

| Information element           | Length | Value | Remark                            |
|-------------------------------|--------|-------|-----------------------------------|
| Network default data priority | 3      | 0     | Network default data priority = 0 |
|                               |        | 1     | Network default data priority = 1 |
|                               |        | etc.  | etc.                              |
|                               |        | 7     | Network default data priority = 7 |

### 28.4.5.20 Not supported SN PDU type

The Not supported SN PDU type information element shall be encoded as defined in table 28.89.

**Table 28.89: Not supported SN PDU type information element contents**

| Information element | Length   | Value | Remark   |
|---------------------|----------|-------|--|
| SN PDU type         | 4        | 0     | SN-ACTIVATE PDP CONTEXT DEMAND<br>SN-ACTIVATE PDP CONTEXT ACCEPT |
|                     |          | 1     | SN-DEACTIVATE PDP CONTEXT ACCEPT                                 |
|                     |          | 2     | SN-DEACTIVATE PDP CONTEXT DEMAND                                 |
|                     |          | 3     | SN-ACTIVATE PDP CONTEXT REJECT                                   |
|                     |          | 4     | SN-UNITDATA  |
|                     |          | 5     | SN-DATA  |
|                     |          | 6     | SN-DATA TRANSMIT REQUEST   |
|                     |          | 7     | SN-DATA TRANSMIT RESPONSE  |
|                     |          | 8     | SN-END OF DATA   |
|                     |          | 9     | SN-RECONNECT   |
|                     |          | 10    | SN-PAGE REQUEST (SwMI to MS)<br>SN-PAGE RESPONSE (MS to SwMI)    |
|                     |          | 11    | Reserved   |
|                     |          | 12    | SN-DATA PRIORITY   |
|                     |          | 13    | SN-MODIFY  |
| others              | Reserved |       |  |

### 28.4.5.21 N-PDU

The N-PDU information element shall be encoded as defined in table 28.90.

**Table 28.90: N-PDU information element contents**

| Information element | Length | Value | Remark  |
|---------------------|--------|-------|---|
| N-PDU               | varies | any   | The length of a N-PDU may range from 0 bits up to the Maximum transmission unit size, which is set at context activation. |

### 28.4.5.22 NSAPI

The NSAPI information element shall be encoded as defined in table 28.91.

**Table 28.91: NSAPI information element contents**

| Information element | Length | Value   | Remark                |
|---------------------|--------|---------|-----------------------|
| NSAPI               | 4      | 0       | Reserved              |
|                     |        | 1 to 14 | Dynamically allocated |
|                     |        | 15      | Reserved              |

### 28.4.5.22a NSAPI additional

The NSAPI additional information element shall be encoded as defined in table 28.92.

**Table 28.92: NSAPI additional information element contents**

| Information element | Length | Value   | Remark                                       |
|---------------------|--------|---------|--|
| NSAPI               | 4      | 0       | Reserved                                     |
|                     |        | 1 to 14 | Dynamically allocated                        |
|                     |        | 15      | Reserved                                     |
| Reserved            | 2      | 0       | Shall be set to zero in the present document |

### 28.4.5.22b NSAPI for reconnection

The NSAPI for reconnection information element shall be encoded as defined in table 28.93.

**Table 28.93: NSAPI for reconnection information element contents**

| Information element | Length | Value   | Remark   |
|---------------------|--------|---------|--|
| NSAPI               | 4      | 0       | Reserved   |
|                     |        | 1 to 14 | Dynamically allocated                                |
|                     |        | 15      | Reserved   |
| Data to send        | 1      | 0       | No data to send for this NSAPI                       |
|                     |        | 1       | SN-DATA PDU or SN-UNITDATA PDU awaiting transmission |
| Reserved            | 1      | 0       | Shall be set to zero in the present document         |

NOTE: The MS is not precluded from setting "data to send" if it wishes to be on a PDCH because it expects imminent reception of data on the downlink or imminent arrival of data for transmission on the uplink.

### 28.4.5.23 Number of compression state slots, TCP

The Number of compression state slots, TCP indicates the maximum value of a context identifier in the space of context identifiers allocated for TCP. The information element shall be encoded as defined in table 28.94.

**Table 28.94: Number of compression state slots, TCP information element contents**

| Information element                    | Length | Value    | Remark  |
|--|--------|----------|---|
| Number of compression state slots, TCP | 8      | 0 to 255 | The value 0 implies having one context. It is recommended that value 0 is not used. |

### 28.4.5.24 Number of compression state slots, non-TCP

The Number of compression state slots, non-TCP indicates the maximum value of a context identifier in the space of context identifiers allocated for non-TCP. The information element shall be encoded as defined in table 28.95.

**Table 28.95: Number of compression state slots, non-TCP information element contents**

| Information element                        | Length | Value       | Remark  |
|--|--------|-------------|---|
| Number of compression state slots, non-TCP | 16     | 0 to 65 535 | The value 0 implies having one context. It is recommended that value 0 is not used. |

### 28.4.5.25 Number of Van Jacobson compression state slots

The number of Van Jacobson compression state slots information element shall be encoded as defined in table 28.96.

**Table 28.96: Number of Van Jacobson compression state slots information element contents**

| Information element                            | Length | Value    | Remark  |
|--|--------|----------|---|
| Number of Van Jacobson compression state slots | 8      | 2 to 255 | It is recommended that values 0 and 1 are not used. |

### 28.4.5.26 Packet data MS Type

The Packet data MS Type information element shall be encoded as defined in table 28.97.

**Table 28.97: Packet data MS Type information element contents**

| Information element | Length | Value  | Remark   |
|---------------------|--------|--------|----------|
| Packet data MS type | 4      | 0      | Type A   |
|                     |        | 1      | Type B   |
|                     |        | 2      | Type C   |
|                     |        | 3      | Type D   |
|                     |        |        |          |
|                     |        | others | Reserved |

### 28.4.5.27 PCOMP

The PCOMP information element shall be encoded as defined in table 28.98.

**Table 28.98: PCOMP information element contents**

| Information element | Length   | Value | Remark                             |
|---------------------|--|-------|------------------------------------|
| PCOMP               | 4  | 0     | No compression                     |
|                     |  | 1     | Van Jacobson compressed TCP/IP     |
|                     |  | 2     | Van Jacobson non-compressed TCP/IP |
|                     |  | 3     | FULL_HEADER                        |
|                     |  | 4     | COMPRESSED_TCP                     |
|                     |  | 5     | COMPRESSED_TCP_NODELTA             |
|                     |  | 6     | COMPRESSED_NON_TCP                 |
|                     |  | 7     | COMPRESSED_RTP_8                   |
|                     |  | 8     | COMPRESSED_RTP_16                  |
|                     |  | 9     | COMPRESSED_UDP_8                   |
|                     |  | 10    | COMPRESSED_UDP_16                  |
|                     |  | 11    | CONTEXT_STATE                      |
| others              | For further standardization (a list of fixed or negotiated algorithms e.g. IPv6) |       |                                    |

### 28.4.5.28 PCOMP negotiation

The PCOMP negotiation information element shall be encoded as defined in table 28.99.

**Table 28.99: PCOMP negotiation information element contents**

| Information element  | Length | Value       | Remark  |
|--|--------|-------------|---|
| PCOMP negotiation  | 8      | bit 1 (LSB) | Van Jacobson TCP/IP header compression (IETF RFC 1144 [29])   |
|  |        | bit 2       | IP header compression (IETF RFC 2507 [35])<br>Enable use of PCOMP values: FULL_HEADER, COMPRESSED_TCP, COMPRESSED_TCP_NODELTA, COMPRESSED_NON_TCP, CONTEXT_STATE (see note 1) |
|  |        | bit 3       | Enable use of PCOMP values: COMPRESSED_RTP_8, COMPRESSED_RTP_16, COMPRESSED_UDP_8, COMPRESSED_UDP_16 and CONTEXT_STATE (IETF RFC 2508 [36]) (see notes 1 and 2)               |
|  |        | bit 4       | Reserved  |
|  |        | bit 5       | Reserved  |
|  |        | bit 6       | Reserved  |
|  |        | bit 7       | Reserved  |
|  |        | bit 8 (MSB) | Reserved  |
| NOTE 1: Bit 3 not set - "CONTEXT_STATE" shall only be used to synchronize TCP context identities - clause 10.2 IETF RFC 2507 [35];<br>Bit 3 set - "CONTEXT_STATE" may also be used to synchronize UDP_8 and UDP_16 context identities - clause 3.3.5 IETF RFC 2508 [36]. |        |             |   |
| NOTE 2: This bit shall be conditional on bit 2 and shall only be set to 1 if bit 2 is also set to 1.   |        |             |   |

### 28.4.5.29 PD service status

The PD service status information element shall be encoded as defined in table 28.100.

**Table 28.100: PD service status information element contents**

| Information element | Length | Value | Remark                                 |
|---------------------|--------|-------|--|
| PD service status   | 1      | 0     | Temporarily unavailable for PD service |
|                     |        | 1     | Available for PD service               |

### 28.4.5.29a PDP context availability

The PDP context availability information element shall be encoded as defined in table 28.101.

**Table 28.101: PDP context availability information element contents**

| Information element      | Length | Value | Remark                        |
|--------------------------|--------|-------|-------------------------------|
| PDP context availability | 3      | 0     | PDP context available for use |
|                          |        | 1     | Schedule suspended            |
|                          |        | 2     | Reserved                      |
|                          |        | etc.  | etc.                          |
|                          |        | 7     | Reserved                      |

## 28.4.5.29b PDP context usage

The PDP context usage information element shall be encoded as defined in table 28.102.

**Table 28.102: PDP context usage information element contents**

| Information element | Length | Value | Remark                    |
|---------------------|--------|-------|---------------------------|
| PDP context usage   | 3      | 0     | Use of schedule paused    |
|                     |        | 1     | Use of PDP context paused |
|                     |        | 2     | Reserved                  |
|                     |        | etc.  | etc.                      |
|                     |        | 7     | Reserved                  |

## 28.4.5.30 PDU priority max

The PDU priority max information element shall be encoded as defined in table 28.103.

**Table 28.103: PDU priority max information element contents**

| Information element | Length | Value | Remark               |
|---------------------|--------|-------|----------------------|
| PDU priority max    | 3      | 0     | Lowest PDU priority  |
|                     |        | etc.  | etc.                 |
|                     |        | 7     | Highest PDU priority |

## 28.4.5.30a Port

The port information element shall be encoded as defined in table 28.104.

**Table 28.104: Port information element contents**

| Information element   | Length | Value | Remark   |
|---|--------|-------|----------|
| Port  | 16     | Any   | See note |
| NOTE: Shall contain a port number in the range 0 to 65 535. |        |       |          |

### 28.4.5.31 Protocol configuration options

The Protocol configuration options information element shall be encoded as defined in table 28.105.

**Table 28.105: Protocol configuration options information element contents**

| Information element   | Length | C/O/M | Value             | Remark   |
|---|--------|-------|-------------------|--|
| Configuration protocol  | 4      | M     | 0000 <sub>2</sub> | PPP<br>All other values are interpreted as PPP in this version of the protocol |
| Protocol identity   | 16     | M     |                   | see notes 1 and 3  |
| Length of protocol identity contents  | 8      | M     |                   | see notes 3 and 4  |
| Protocol identity contents  | varies | M     |                   | see notes 2 and 3  |
| <p>NOTE 1: Contains the hexadecimal coding of the configuration protocol identifier as defined in IETF RFC 3232 [38]. Bit 8 of the first octet of the protocol identifier information element shall contain the most significant bit and bit 1 of the second octet of the protocol identifier information element shall contain the least significant bit.<br/>At least the following protocol identifiers shall be supported in this version of the protocol:</p> <ul style="list-style-type: none"> <li>- C023H = (PAP); and</li> <li>- C223H (CHAP).</li> </ul> <p>The support of other protocol identifiers is implementation dependent and outside the scope of the present document. If the configuration protocol options list contains a protocol identifier that is not supported by the receiving entity the corresponding unit shall be discarded.</p> <p>NOTE 2: The protocol identifier contents information element of each set corresponds to a "Packet" as defined in IETF RFC 1661 [30] that is stripped off the "Protocol field" and the "Padding" octets (i.e. the protocol identifier contents field is constructed from fields "Code", "Identifier", "Length" and "Data" as described in IETF RFC 1661 [30]). The detailed coding of the protocol identifier contents field is specified in the RFC that is associated with the protocol identifier of that unit.</p> <p>NOTE 3: These information elements shall be repeated as a set for each protocol.</p> <p>NOTE 4: The "length of protocol identity contents" information element shall indicate the length of the "protocol identity contents" in octets.</p> |        |       |                   |  |

## 28.4.5.31a QoS

The QoS information element shall be encoded as defined in table 28.106.

**Table 28.106: QoS information element contents**

| Information element   | Length | Type | C/O/M | Remark             |
|---|--------|------|-------|--------------------|
| Background class request  | 1      | 1    | M     |                    |
| CONTEXT_READY timer   | 4      |      | C     | See note 1         |
| Asymmetrical QoS  | 1      |      | C     | See note 1         |
| QoS set   | 20     |      | C     | See notes 1 and 2  |
| QoS set   | 20     |      | C     | See note 3         |
| QoS filter included   | 1      |      | C     | See notes 1 and 4  |
| QoS filter  | Varies |      | C     | See notes 1 and 5  |
| Scheduled access information included   | 1      |      | C     | See notes 1 and 6  |
| Scheduled access  | Varies |      | C     | See note 7         |
| Additional QoS information A included   | 1      |      | C     | See note 1         |
| Additional QoS information A  | 16     |      | C     | See notes 8 and 9  |
| Additional QoS information B included   | 1      |      | C     | See note 1         |
| Additional QoS information B  | 16     |      | C     | See notes 8 and 10 |
| NOTE 1: This information element shall be present only if "background class request" value is equal to "any data class".  |        |      |       |                    |
| NOTE 2: If "asymmetrical QoS" value is equal to "symmetrical QoS" this information element specifies a common uplink and downlink QoS; if "asymmetrical QoS" value is equal to "asymmetrical QoS" it specifies only the uplink QoS. |        |      |       |                    |
| NOTE 3: This information element shall be present only if "asymmetrical QoS" value is equal to "asymmetrical QoS" and specifies the downlink QoS.   |        |      |       |                    |
| NOTE 4: This information element shall be set to "QoS filter not included" if the QoS information element relates to a primary PDP context.   |        |      |       |                    |
| NOTE 5: This information element shall be present only if "QoS filter included" value is equal to "QoS filter included". See clause 28.3.9 for usage.   |        |      |       |                    |
| NOTE 6: If the SwMI does not support a schedule on this PDP context, it shall set "scheduled access information included" value to "not included".  |        |      |       |                    |
| NOTE 7: This information element shall be present only if "scheduled access information included" value is equal to "included".   |        |      |       |                    |
| NOTE 8: This information element shall not be used in the protocol defined in the present document. The contents of this element, if present, shall be ignored.   |        |      |       |                    |
| NOTE 9: This information element shall be present only if "additional QoS information A included" value is equal to "included".   |        |      |       |                    |
| NOTE 10: This information element shall be present only if "additional QoS information B included" value is equal to "included".  |        |      |       |                    |

## 28.4.5.31b QoS filter

The QoS filter information element shall be encoded as defined in table 28.107.

**Table 28.107: QoS filter information element contents**

| Information element  | Length | Type | C/O/M | Remark            |
|--|--------|------|-------|-------------------|
| QoS filter operation   | 2      | 1    | M     |                   |
| QoS filter type  | 4      | 1    | M     |                   |
| Port   | 16     |      | C     | See notes 1 and 2 |
| Port   | 16     |      | C     | See notes 3 and 4 |
| Diffserv filter  | 16     |      | C     | See note 5        |
| Reserved   | 16     |      | C     | See note 6        |
| Reserved   | 16     |      | C     | See note 7        |
| NOTE 1: This information element shall be present only if "QoS filter type" has a value in the range 1 to 6.   |        |      |       |                   |
| NOTE 2: If "QoS filter type " has a value in the range 1 to 3 this information element shall contain a port number. If the "QoS filter type" has a value in the range 4 to 6, this information element shall contain the lower limit of a range of port numbers. |        |      |       |                   |
| NOTE 3: This information element shall be present only if "QoS filter type" has a value in the range 4 to 6.   |        |      |       |                   |
| NOTE 4: This information element shall contain the upper limit of a range of port numbers.   |        |      |       |                   |
| NOTE 5: This information element shall be present only if "QoS filter type" has value 7.   |        |      |       |                   |
| NOTE 6: This information element shall be present only if "QoS filter type" has a value in the range 8 to 15.  |        |      |       |                   |
| NOTE 7: This information element shall be present only if "QoS filter type" has a value in the range 12 to 15.   |        |      |       |                   |

## 28.4.5.31c QoS filter included

The QoS filter included information element shall be encoded as defined in table 28.108.

**Table 28.108: QoS filter included information element contents**

| Information element | Length | Value | Remark                  |
|---------------------|--------|-------|-------------------------|
| QoS filter included | 1      | 0     | QoS filter not included |
|                     |        | 1     | QoS filter included     |

## 28.4.5.31d QoS filter operation

The QoS filter operation information element shall be encoded as defined in table 28.109.

**Table 28.109: QoS filter operation information element contents**

| Information element  | Length | Value | Remark  |
|----------------------|--------|-------|---|
| QoS filter operation | 2      | 0     | Add this QoS filter to any existing QoS filter for this PDP context     |
|                      |        | 1     | Replace any existing QoS filter for this PDP context by this QoS filter |
|                      |        | 2     | Remove this QoS filter from this PDP context                            |
|                      |        | 3     | Reserved  |

## 28.4.5.31e QoS filter type

The port type information element shall be encoded as defined in table 28.110.

Table 28.110: Port type information element contents

| Information element | Length | Value   | Remark  |
|---------------------|--------|---------|---|
| Port type           | 4      | 0       | Use automatic QoS filter for this PDP context until the QoS filter for this PDP context is replaced |
|                     |        | 1       | All types of port   |
|                     |        | 2       | UDP ports   |
|                     |        | 3       | TCP ports   |
|                     |        | 4       | Range of all types of port  |
|                     |        | 5       | Range of UDP ports  |
|                     |        | 6       | Range of TCP ports  |
|                     |        | 7       | Diffserv filter   |
|                     |        | 8 to 15 | Reserved  |

## 28.4.5.31f QoS set

The QoS set information element shall be encoded as defined in table 28.111.

Table 28.111: QoS set information element contents

| Information element     | Length | Type | C/O/M | Remark |
|-------------------------|--------|------|-------|--------|
| Data class              | 3      | 1    | M     |        |
| Minimum peak throughput | 4      | 1    | M     |        |
| Mean throughput         | 5      | 1    | M     |        |
| Mean active throughput  | 4      | 1    | M     |        |
| Delay class             | 2      | 1    | M     |        |
| Reliability class       | 2      | 1    | M     |        |

## 28.4.5.32 READY timer

The READY timer information element shall be encoded as defined in table 28.112.

Table 28.112: READY timer information element contents

| Information element | Length   | Value | Remark   |
|---------------------|----------|-------|----------|
| READY timer         | 4        | 0     | Reserved |
|                     |          | 1     | 200 ms   |
|                     |          | 2     | 500 ms   |
|                     |          | 3     | 700 ms   |
|                     |          | 4     | 1 s      |
|                     |          | 5     | 2 s      |
|                     |          | 6     | 3 s      |
|                     |          | 7     | 5 s      |
|                     |          | 8     | 10 s     |
|                     |          | 9     | 20 s     |
|                     |          | 10    | 30 s     |
|                     |          | 11    | 60 s     |
|                     |          | 12    | 120 s    |
|                     |          | 13    | 180 s    |
|                     |          | 14    | 300 s    |
| 15                  | Reserved |       |          |

### 28.4.5.32a Reliability class

The Reliability class information element shall be encoded as defined in table 28.113.

**Table 28.113: Reliability class information element contents**

| Information element                                   | Length | Value | Remark   |
|---|--------|-------|----------|
| Reliability class (see note)                          | 2      | 0     | Low      |
|   |        | 1     | Moderate |
|   |        | 2     | High     |
|   |        | 3     | Reserved |
| NOTE: Reliability classes are defined in table 28.11. |        |       |          |

### 28.4.5.33 Reply requested

The Reply requested information element shall be encoded as defined in table 28.114.

**Table 28.114: Reply requested information element contents**

| Information element | Length | Value | Remark                       |
|---------------------|--------|-------|------------------------------|
| Reply requested     | 1      | 0     | SNDCP response not requested |
|                     |        | 1     | SNDCP response requested     |

## 28.4.5.34 Resource request

The resource request information element shall be coded as defined in table 28.115. This information element refers only to phase modulation resources.

Table 28.115: Resource request information element contents

| Information element  | Length  | C/O/M | Value            | Remark   |
|--|---------|-------|------------------|--|
| Connection symmetry<br>(see note 8)  | 1       | M     | 0                | Symmetric phase modulation connection                        |
|  |         |       | 1                | Asymmetric phase modulation connection                       |
| Data transfer throughput<br>(mean value)<br>(see notes 1 and 5)  | 3       | M     | 000 <sub>2</sub> | Network dependent minimum                                    |
|  |         |       | 001 <sub>2</sub> | 1/32 of maximum  |
|  |         |       | 010 <sub>2</sub> | 1/16 of maximum  |
|  |         |       | 011 <sub>2</sub> | 1/8 of maximum   |
|  |         |       | 100 <sub>2</sub> | 1/4 of maximum   |
|  |         |       | 101 <sub>2</sub> | 1/2 of maximum   |
|  |         |       | 110 <sub>2</sub> | Unspecified phase modulation resource<br>(see notes 7 and 8) |
| 111 <sub>2</sub>   | Maximum |       |                  |  |
| Number of $\pi/4$ -DQPSK<br>timeslots on uplink or on<br>uplink and downlink<br>(see notes 2 and 8)  | 2       | M     | 00 <sub>2</sub>  | 1 timeslot   |
|  |         |       | 01 <sub>2</sub>  | 2 timeslots  |
|  |         |       | 10 <sub>2</sub>  | 3 timeslots  |
|  |         |       | 11 <sub>2</sub>  | 4 timeslots  |
| Number of $\pi/4$ -DQPSK<br>timeslots on downlink (see<br>notes 3 and 8)   | 2       | C     | 00 <sub>2</sub>  | 1 timeslot   |
|  |         |       | 01 <sub>2</sub>  | 2 timeslots  |
|  |         |       | 10 <sub>2</sub>  | 3 timeslots  |
|  |         |       | 11 <sub>2</sub>  | 4 timeslots  |
| Full phase modulation<br>capability<br>(see notes 4 and 6)   | 2       | M     | 00 <sub>2</sub>  | 1 timeslot   |
|  |         |       | 01 <sub>2</sub>  | 2 timeslots  |
|  |         |       | 10 <sub>2</sub>  | 3 timeslots  |
|  |         |       | 11 <sub>2</sub>  | 4 timeslots  |
| Reserved   | 2       | M     | 00 <sub>2</sub>  | Reserved   |
|  |         |       | 01 <sub>2</sub>  | Reserved   |
|  |         |       | 10 <sub>2</sub>  | Reserved   |
|  |         |       | 11 <sub>2</sub>  | Shall be set to 11 <sub>2</sub> in the present document      |
| NOTE 1: The BS may use a control channel as a general packet data channel, supporting advanced links for many MSs, where each MS may be offering/receiving data packets at a low rate or intermittently. This parameter gives the BS the necessary information for planning its resource allocations.  |         |       |                  |  |
| NOTE 2: In case of symmetric connection (i.e. Connection symmetry information element set to "0") the "number of $\pi/4$ -DQPSK timeslots on uplink or on uplink and downlink" information element indicates the number of phase modulation timeslots per TDMA frame requested both on uplink and downlink direction.  |         |       |                  |  |
| NOTE 3: Shall be conditional on the value of the Connection symmetry information element. The information element is present only for asymmetric connection (i.e. Connection symmetry information element set to "1"). If present, it indicates the number of phase modulation timeslots per TDMA frame requested on the downlink.   |         |       |                  |  |
| NOTE 4: This information element indicates the MS's maximum capability to handle phase modulation physical resources. It applies to $\pi/4$ -DQPSK channels and, if supported, to D8PSK channels.  |         |       |                  |  |
| NOTE 5: The data transfer throughput shall be specified relative to the number of $\pi/4$ -DQPSK timeslots requested.  |         |       |                  |  |
| NOTE 6: The BS shall not allocate the MS more phase modulation timeslots per TDMA frame than indicated by the "full phase modulation capability" information element.  |         |       |                  |  |
| NOTE 7: An MS that cannot use a multi-slot phase modulation channel shall not set the "Data transfer throughput (mean value)" information element to "110 <sub>2</sub> " (unspecified phase modulation resource).  |         |       |                  |  |
| NOTE 8: If the "Data transfer throughput (mean value)" information element is set to value "110 <sub>2</sub> " (unspecified phase modulation resource), the "connection symmetry" information element shall be set to "0" (symmetric phase modulation connection) and the "number of $\pi/4$ -DQPSK timeslots on uplink or on uplink and downlink" information element shall be set equal to the "full phase modulation capability" information element. |         |       |                  |  |

## 28.4.5.35 RESPONSE\_WAIT timer

The RESPONSE\_WAIT timer information element shall be encoded as defined in table 28.116.

**Table 28.116: RESPONSE\_WAIT timer information element contents**

| Information element | Length   | Value | Remark |
|---------------------|----------|-------|--------|
| RESPONSE_WAIT timer | 4        | 0     | 400 ms |
|                     |          | 1     | 600 ms |
|                     |          | 2     | 800 ms |
|                     |          | 3     | 1 s    |
|                     |          | 4     | 2 s    |
|                     |          | 5     | 3 s    |
|                     |          | 6     | 4 s    |
|                     |          | 7     | 5 s    |
|                     |          | 8     | 10 s   |
|                     |          | 9     | 15 s   |
|                     |          | 10    | 20 s   |
|                     |          | 11    | 30 s   |
|                     |          | 12    | 40 s   |
|                     |          | 13    | 50 s   |
|                     |          | 14    | 60 s   |
| 15                  | Reserved |       |        |

## 28.4.5.35a Scheduled access

The scheduled access information element shall be encoded as defined in table 28.117.

**Table 28.117: Scheduled access information element contents**

| Information element  | Length | C/O/M | Value | Remark                         |
|--|--------|-------|-------|--------------------------------|
| Schedule repetition period   | 10     | M     | 0     | Reserved                       |
|  |        |       | 1     | Reserved                       |
|  |        |       | etc.  | etc.                           |
|  |        |       | 3     | Reserved                       |
|  |        |       | 4     | 4 slot durations (see note 1)  |
|  |        |       | 5     | 5 slot durations               |
|  |        |       | etc.  | etc.                           |
|  |        |       | 706   | 706 slot durations (10,00 s)   |

| NOTE 1: One slot has a duration of 85/6 ms.  |        |       |       |                                |
| NOTE 2: This information element shall be present as many times as indicated by the "Scheduled number of SN-DATA or SN-UNITDATA PDUs per grant" information element. |        |       |       |                                |

## 28.4.5.35b Scheduled access information included

The "Scheduled access information included" information element shall be encoded as defined in table 28.118.

**Table 28.118: Scheduled access information included information element contents**

| Information element                   | Length | Value | Remark       |
|---------------------------------------|--------|-------|--------------|
| Scheduled access information included | 1      | 0     | Not included |
|                                       |        | 1     | Included     |

## 28.4.5.36 SNDCP version

The SNDCP version information element shall be encoded as defined in table 28.119.

**Table 28.119: SNDCP version information element contents**

| Information element | Length | Value  | Remark   |
|---------------------|--------|--------|--|
| SNDCP version       | 4      | 0      | Reserved   |
|                     |        | 1      | The first version of the TETRA Packet Data specification |
|                     |        | others | Reserved   |

## 28.4.5.37 SNDCP network endpoint identifier

The SNDCP network endpoint identifier information element shall be encoded as defined in table 28.120.

**Table 28.120: SNDCP endpoint identifier information element contents**

| Information element       | Length | Value | Remark |
|---------------------------|--------|-------|--------|
| SNDCP endpoint identifier | 16     |       |        |

## 28.4.5.38 SN PDU type

The PDU type information element shall be encoded as defined in table 28.121.

**Table 28.121: SN PDU type information element contents**

| Information element | Length   | Value | Remark  |
|---------------------|----------|-------|---|
| SN PDU type         | 4        | 0     | SN-ACTIVATE PDP CONTEXT DEMAND (MS to SwMI)<br>SN-ACTIVATE PDP CONTEXT ACCEPT (SwMI to MS)              |
|                     |          | 1     | SN-DEACTIVATE PDP CONTEXT ACCEPT  |
|                     |          | 2     | SN-DEACTIVATE PDP CONTEXT DEMAND  |
|                     |          | 3     | SN-ACTIVATE PDP CONTEXT REJECT  |
|                     |          | 4     | SN-UNITDATA   |
|                     |          | 5     | SN-DATA   |
|                     |          | 6     | SN-DATA TRANSMIT REQUEST  |
|                     |          | 7     | SN-DATA TRANSMIT RESPONSE   |
|                     |          | 8     | SN-END OF DATA  |
|                     |          | 9     | SN-RECONNECT  |
|                     |          | 10    | SN-PAGE REQUEST (SwMI to MS)<br>SN-PAGE RESPONSE (MS to SwMI)   |
|                     |          | 11    | SN-NOT SUPPORTED  |
|                     |          | 12    | SN-DATA PRIORITY, see "Data priority sub-type"<br>(clause 28.4.5.7g) for definition of SN PDU sub-type. |
|                     |          | 13    | SN-MODIFY, see "Modify sub-type" (clause 28.4.5.19f) for<br>definition of SN PDU sub-type               |
| Others              | Reserved |       |   |

## 28.4.5.39 STANDBY timer

The STANDBY timer information element shall be encoded as defined in table 28.122.

**Table 28.122: STANDBY timer information element contents**

| Information element | Length  | Value | Remark   |
|---------------------|---------|-------|----------|
| STANDBY timer       | 4       | 0     | Reserved |
|                     |         | 1     | 10 s     |
|                     |         | 2     | 30 s     |
|                     |         | 3     | 1 min    |
|                     |         | 4     | 5 min    |
|                     |         | 5     | 10 min   |
|                     |         | 6     | 30 min   |
|                     |         | 7     | 1 hour   |
|                     |         | 8     | 2 hours  |
|                     |         | 9     | 3 hours  |
|                     |         | 10    | 6 hours  |
|                     |         | 11    | 12 hours |
|                     |         | 12    | 24 hours |
|                     |         | 13    | 48 hours |
|                     |         | 14    | 72 hours |
| 15                  | Forever |       |          |

## 28.4.5.40 SwMI IPv6 Information

The "SwMI IPv6 information" information element shall be encoded as defined in table 28.123.

**Table 28.123: SwMI IPv6 Information information element contents**

| Information element              | Length | C/O/M | Value | Remark        |
|----------------------------------|--------|-------|-------|---------------|
| IPv6 Network Prefix              | 64     | M     |       |               |
| Prefix Valid Lifetime            | 32     | M     |       |               |
| On-Link Flag                     | 1      | M     |       |               |
| Autonomous Address Configuration | 1      | M     | 0     | Not Supported |
|                                  |        |       | 1     | Supported     |

### 28.4.5.41 SwMI Mobile IPv4 Information

The "SwMI Mobile IPv4 information" information element shall be encoded as defined in table 28.124.

**Table 28.124: SwMI Mobile IPv4 Information information element contents**

| Information element          | Length | C/O/M | Value | Remark                           |
|------------------------------|--------|-------|-------|----------------------------------|
| FA Care of Address           | 32     | M     |       |                                  |
| Sequence Number              | 16     | M     |       |                                  |
| FA Registration Lifetime     | 16     | M     |       |                                  |
| Register via FA (R)          | 1      | M     | 0     | Registration via FA not required |
|                              |        |       | 1     | Registration via FA required     |
| FA Busy (B)                  | 1      | M     | 0     | Accepting Registrations          |
|                              |        |       | 1     | Accepting no Registrations       |
| Home Agent (H)               | 1      | M     | 0     | Offers no HA Services            |
|                              |        |       | 1     | Offers HA Services               |
| Foreign Agent (F)            | 1      | M     | 0     | Offers no HA Services            |
|                              |        |       | 1     | Offers HA Services               |
| Minimal Encapsulation (M)    | 1      | M     | 0     | Not Supported                    |
|                              |        |       | 1     | Supported                        |
| GRE Encapsulation (G)        | 1      | M     | 0     | Not Supported                    |
|                              |        |       | 1     | Supported                        |
| Van Jacobsen Compression (V) | 1      | M     | 0     | Not Supported                    |
|                              |        |       | 1     | Supported                        |

### 28.4.5.42 Transmit response reject cause

The Transmit response reject cause information element shall be encoded as defined in table 28.125.

**Table 28.125: Transmit response reject cause information element contents**

| Information element            | Length | Value  | Remark  |
|--------------------------------|--------|--------|---|
| Transmit Response Reject Cause | 8      | 0      | Undefined                                       |
|                                |        | 1      | Unknown NSAPI                                   |
|                                |        | 2      | System resources not available                  |
|                                |        | 23     | Requested minimum peak throughput not available |
|                                |        | 25     | Requested schedule not available                |
|                                |        | 34     | SNDCP service temporarily not available         |
|                                |        | others | Reserved  |

### 28.4.5.43 Type identifier in accept

The Type identifier in accept information element shall be encoded as defined in table 28.126.

**Table 28.126: Type Identifier in Accept information element contents**

| Information element       | Length | Value  | Remark               |
|---------------------------|--------|--------|----------------------|
| Type identifier in accept | 3      | 0      | No address           |
|                           |        | 1      | IPv4 Static Address  |
|                           |        | 2      | IPv4 Dynamic Address |
|                           |        | 3 to 7 | Reserved             |

## 28.4.5.44 Type 3/4 element identifier

The Type 3/4 element identifier information element shall be encoded as defined in table 28.127.

**Table 28.127: Type 3/4 element identifier information element contents**

| Information element         | Length | Value  | Remark                         |
|-----------------------------|--------|--------|--------------------------------|
| Type 3/4 element identifier | 4      | 0      | DCOMP negotiation              |
|                             |        | 1      | Protocol configuration options |
|                             |        | 2      | Data priority details          |
|                             |        | 3      | QoS                            |
|                             |        | 4      | NSAPI additional               |
|                             |        | 5      | NSAPI for reconnection         |
|                             |        | others | Reserved                       |

28.4.5.45 V.42bis compression request,  $P_0$ 

The Recommendation ITU-T V.42bis [27] compression request,  $P_0$  information element shall be encoded as defined in table 28.128.

**Table 28.128: Recommendation ITU-T V.42bis data compression request parameters information element contents**

| Information element                   | Length | Value | Remark   |
|---------------------------------------|--------|-------|--|
| V.42bis [27] data compression request | 2      | 0     | compress neither direction                     |
|                                       |        | 1     | compress initiator-to-responder direction only |
|                                       |        | 2     | compress responder-to-initiator direction only |
|                                       |        | 3     | compress both directions                       |

## 28.4.5.46 V.42bis data compression parameters

The Recommendation ITU-T V.42bis [27] data compression parameters information element shall be encoded as defined in table 28.129.

**Table 28.129: Recommendation ITU-T V.42bis data compression parameters information element contents**

| Information element                                     | Length | Type | C/O/M | Remark |
|---|--------|------|-------|--------|
| Recommendation ITU-T V.42bis [27] compression request   | 2      | 1    | M     |        |
| Recommendation ITU-T V.42bis [27] number of codewords   | 16     | 1    | M     |        |
| Recommendation ITU-T V.42bis [27] maximum string length | 8      | 1    | M     |        |

28.4.5.47 V.42bis maximum string length,  $P_2$ 

The Recommendation ITU-T V.42bis [27] maximum string length,  $P_2$  information element shall be encoded as defined in table 28.130.

**Table 28.130: Recommendation ITU-T V.42bis maximum string length information element contents**

| Information element  | Length | Value      | Remark   |
|--|--------|------------|--|
| Recommendation ITU-T V.42bis [27] maximum string length, $P_2$ | 8      | 0 to 5     | Reserved   |
|  |        | 6 to 250   | Maximum number of characters in an uncompressed data string that is accepted to be encoded |
|  |        | 251 to 255 | Reserved   |

### 28.4.5.48 V.42bis number of codewords, $P_1$

The Recommendation ITU-T V.42bis [27] number of codewords,  $P_1$  information element shall be encoded as defined in table 28.131.

**Table 28.131: Recommendation ITU-T V.42bis number of codewords information element contents**

| Information element  | Length | Value         | Remark   |
|--|--------|---------------|--|
| Recommendation ITU-T V.42bis [27] number of codewords, $P_1$ | 16     | 0 to 511      | Reserved   |
|  |        | 512 to 65 535 | Maximum number of codewords in the compressor dictionary. Suitable default value for TETRA packet data TBD |

## 28.5 Timers and constants

### 28.5.1 Timers

#### 28.5.1.1 PDP\_ACTIVATE\_WAIT

PDP\_ACTIVATE\_WAIT timer has a fixed value of 30 s. The timer is valid for MS SNDCCP only.

#### 28.5.1.2 PDP\_DEACTIVATE\_WAIT

PDP\_DEACTIVATE\_WAIT timer has a fixed value of 180 s. The timer is valid for MS SNDCCP only.

#### 28.5.1.2a PDP\_MODIFY\_WAIT

PDP\_MODIFY\_WAIT timer has a fixed value of 30 s. The timer is valid for MS SNDCCP only.

#### 28.5.1.3 READY

READY timer value is always given in SN-ACTIVATE PDP CONTEXT ACCEPT PDU. The latest received SN-ACTIVATE PDP CONTEXT ACCEPT PDU values shall be used.

#### 28.5.1.4 STANDBY

STANDBY timer value is always given in SN-ACTIVATE PDP CONTEXT ACCEPT PDU. The latest received SN-ACTIVATE PDP CONTEXT ACCEPT PDU values shall be used.

#### 28.5.1.5 DATA\_PRIORITY\_REQUEST\_WAIT

DATA\_PRIORITY\_REQUEST\_WAIT timer has a fixed value of 30 s. The timer is valid for MS SNDCCP only.

#### 28.5.1.6 RESPONSE\_WAIT

RESPONSE\_WAIT timer value is always given in SN-ACTIVATE PDP CONTEXT ACCEPT PDU. The latest received SN-ACTIVATE PDP CONTEXT ACCEPT PDU values shall be used.

#### 28.5.1.7 SERVICE\_CHANGE

SERVICE\_CHANGE timer has a fixed value of 3 s. The timer is valid for MS SNDCCP only.

#### 28.5.1.8 CONTEXT\_READY

CONTEXT\_READY timer value obtains its value from the READY timer value or the QoS information element (if present) of the SN-ACTIVATE PDP CONTEXT ACCEPT and the SN-MODIFY PDP CONTEXT RESPONSE PDUs.

## 28.5.2 Constants

RETRY\_ACTIVATION has a fixed value 3 times. The constant is valid for MS SMDCP only.

RETRY\_MODIFICATION has a fixed value 3 times. The constant is valid for MS SMDCP only.

---

## 29 SDS-TL service and protocol

### 29.0 General

The Short Data Service (SDS) as defined in clauses 13 and 14 consists of a pre-coded message service and a user-defined message service. The user-defined message service provides a bearer service for 16 bits, 32 bits, 64 bits or up to 2 047 bits of application-defined data. This bearer service and the underlying protocol ensure reliable delivery of user-defined data over the air interface. However, in order to ensure inter-operability of different applications using SDS service, an additional header information is defined to support Short Data Service Transport Layer (SDS-TL) data transfer service.

This clause defines a layer 4 protocol for the SDS user defined data type 4 (this is carried within the 2 047 bits of application defined data).

This additional protocol layer, hereafter called the SDS Transport Layer (SDS-TL), defines means which enhances the service provided by the layer 3 Short Data Service protocol to provide protocol mechanisms for end-to-end acknowledgement, forwarding, storing and forwarding and to ensure that applications using this service interpret the user data in the same way. Because of the additional header, this protocol is only for use with SDS type 4. In order to guarantee that the basic SDS user data type-4 service and the SDS-TL data transfer service do not disturb each other a protocol header is also added into the basic SDS user data type-4 service, refer to clauses 13.3 and 29.3.2.1.

This clause specifies:

- the services provided by the SDS-TL;
- the functional requirements for the SDS-TL;
- SDS-TL procedures for specific transmission and reception of SDS user-defined data messages;
- the encoding of the Protocol Data Units (PDUs) defined by SDS-TL.

The SDS-TL protocol provides the following services:

- point-to-point message transfer;
- point-to-multipoint message transfer;
- broadcast message transfer;
- end-to-end acknowledgement of message receipt and consumption by application;
- support for multiple application protocols;
- transfer of long messages by dissection into individual SDS-TL messages for transmission and reconstruction by the receiver.

The SDS-TL supports the following types of application which use the SDS bearer service:

- standard applications which use the SDS-TL services;
- non-standard applications which use the SDS-TL services;
- standard applications which do not use the SDS-TL services;
- non-standard applications which do not use the SDS-TL services.

## 29.1 Overview of SDS-TL

### 29.1.1 Protocol architecture

The SDS-TL data transfer service enhances the SDS type 4 data service and in effect replaces SDS type 4 data service to the user application. Figure 29.1 shows the position of the SDS-TL protocol in the MS protocol stack. The SDS-TL entity access the same layer control information as CMCE. The layer control and related primitives are not presented in figure 29.1 The present document does not define a base station protocol architecture or user application SAPs for SDS-TL within the SwMI or in a storing/forwarding entity (service centre).

**Figure 29.1: SDS-TL position in TETRA protocol stack**

SDS-TL adds a layer of protocol functionality to the SDS user-defined type 4 message protocol which is accessed using the TNSDS-UNITDATA request/indication primitives as defined in clause 13 through the TNSDS-SAP. Note that the pre-coded message service and type 1, 2 and 3 short data message service, also provided by the SDS protocol entity within CMCE, shall still be accessed from a user application using the TNSDS-STATUS and TNSDS-UNITDATA request/indication primitives; there is no other SDS-TL protocol functionality for these services except that the SDS-TL protocol uses a range of STATUS PDUs for acknowledgement purposes.

The present document defines in clause 29.5 standardized protocols, which use services of the TNSDS-SAP via SDS-TL-SAP. Those protocols shall run parallel to each other and other protocols utilizing SDS-TL without any interactions.

- NOTE 1: In clause 29 terminology "SDS DATA PDU" is used to indicate either U-SDS DATA or D-SDS DATA PDU or an information element of it as defined in clause 14. SDS-TL PDUs refer to the PDUs defined in clause 29 and transported inside in the User-defined data-4 information element of the SDS DATA PDU.
- NOTE 2: The term "message" is used in service descriptions when the actual PDU name is not relevant.
- NOTE 3: The external subscriber number (information element) may be present both as a part of the SDS DATA PDU and as a part of the SDS-TL PDU inside the forward address information element. The position of the external subscriber number defines its meaning and is indicated when necessary.
- NOTE 4: The layer control includes information that is provided by MLE-BREAK and MLE-DISABLE primitives such as "Permitted services in graceful service degradation mode" and "Permitted services in temporary disabled mode".

## 29.1.2 Addressing

The SDS-TL layer modifies network layer addressing of the SDS, when storing/forwarding entity capability is used. The storing/forwarding entity capabilities can be used to deliver store and forward functionality. The sending entity will always indicate at the U/D-SDS DATA PDU the address of the next node. When the next node is a storing/forwarding entity, then the final address will be inside the SDS-TL PDU as a forward address. When the sending entity is the storing/forwarding entity then its address is as the source address in the SDS-DATA PDU and the real source address is in the SDS-TL PDU in the forward address information element. Refer to clause 29.3.1 for further details.

In the protocol model, the external subscriber number (MS-ISDN number) of the sending user is known in the SwMI based on the ITSI of the subscriber and the sending MS does not send it. It is also assumed that the MS user application knows its MS-ISDN number from its ITSI and does not receive it as an additional external subscriber number. MS may use an MS-ISDN number as a destination address in the external subscriber number information element either in the SDS DATA PDU or in the forward address information element and may receive it as a source address in the external subscriber number information element either in the SDS DATA PDU or in the forward address information element.

When MS uses the external subscriber number as a destination address with storing/forwarding entity there is no gateway address inside the forward address information element for the external subscriber or MS-ISDN user and it is assumed that the SwMI or the storing/forwarding entity can route the message to a proper gateway or destination.

NOTE 1: The service primitives and protocol PDUs use the same parameter and information element names, which may give a wrong impression of the usage of those parameters and information elements in a storing/forwarding entity case, refer to relevant notes in the definition tables.

NOTE 2: The storing/forwarding entity can be either:

- storing/forwarding entity with basic function to deliver messages to MSs that are not available at the moment the message is received in the storing/forwarding entity, there may also server functionalities that are outside the scope of the present document;
- forwarding entity with a basic function other than storing and forwarding such as server functionalities, normally forwarding entity should not store the message for a later delivery. The forwarding entity functions other than delivering messages to the indicated destinations are outside the scope of the present document.

## 29.1.3 SDS-TL Requirement to SDS and STATUS services

### 29.1.3.1 Requirements to MS

In order to support SDS-TL data transport service the MS shall support SDS type 4 data service at TNSDS-SAP as defined in clause 13 and transportation a range of status values, refer to clause 29.4.2.3.

### 29.1.3.2 Requirements to the SwMI

In order to support SDS-TL data transport service the SwMI shall support SDS type 4 data and status services as defined in clause 13.

## 29.2 SDS-TL Service Descriptions

### 29.2.0 General

The following service descriptions describe the SDS-TL services provided to the higher layers in the MS protocol stack.

#### 29.2.1 Services available at the SDS-TL-SAP

The SDS-TL data transfer service shall provide the means whereby SDU are transmitted from a source to a destination in a reliable manner. The source can request confirmation of reception and consumption from the destination. The reception and consumption confirmation can also be transferred in a reliable manner.

The reliable aspect of the transfer can either be achieved transparently through the SwMI or by utilizing storing/forwarding entity capability of the SwMI. The implementation of the storing/forwarding entity (service centre) is outside the scope of the present document.

## 29.2.2 Service primitives at the SDS-TL-SAP

**TLSDS-TRANSFER request:** the primitive shall be used by the SDS-TL entity to send data to a peer entity. Parameters indicate whether reporting is requested.

**TLSDS-TRANSFER indication:** the primitive shall be used by the SDS-TL to pass to the SDS-TL entity data which has been received from a peer entity.

Table 29.1 gives parameters for the TLSDS-TRANSFER primitives, when no storing/forwarding entity is used.

**Table 29.1: Parameters for the TLSDS-TRANSFER primitive without storing/forwarding addressing**

| Parameter  | Request        | Indication     |
|--|----------------|----------------|
| Access priority  | O              | -              |
| Traffic stealing   | O              | -              |
| Area selection   | O              | -              |
| Called party   | (see note 1)   | (see note 5)   |
| Called party SNA   | O (see note 2) | -              |
| Called party SSI   | M (see note 2) | M              |
| Called party extension   | O (see note 2) | M              |
| External subscriber number (called party)  | O              | -              |
| Received address type  | -              | O              |
| Calling party  | - (see note 3) | (see note 6)   |
| Calling party SSI  | -              | M              |
| Calling party extension  | -              | M              |
| External subscriber number (calling party)   | -              | O              |
| Protocol identifier  | M              | M              |
| Delivery report request  | M              | M              |
| Service selection  | M              | -              |
| Short form report  | -              | M              |
| Storage/forward control  | O              | O              |
| Validity period  | O              | O              |
| Message reference handle   | M              | -              |
| Message reference  | -              | M              |
| Time stamp   | O (see note 7) | O (see note 7) |
| User data  | O              | O              |
| NOTE 1: This parameter shall indicate the address of the destination entity.   |                |                |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                |                |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                |                |
| NOTE 4: Void.  |                |                |
| NOTE 5: This parameter value shall indicate "Called party SSI" and "Called party extension".   |                |                |
| NOTE 6: This parameter value shall indicate "Calling party SSI" and "Calling party extension".   |                |                |
| NOTE 7: Availability of this parameter is protocol dependent refer to clauses 29.3.2.9 and 29.5.3.3. Normally the SwMI will add the timestamp to the message and the timestamp in the request is to support those cases where that service is not available in the SwMI. |                |                |

Table 29.2 gives parameters for the TLSDS-TRANSFER primitives, when a storing/forwarding entity is used.

**Table 29.2: Parameters for the TLSDS-TRANSFER primitive with storing/forwarding addressing**

| Parameter   | Request         | Indication      |
|---|-----------------|-----------------|
| Access priority   | O               | -               |
| Traffic stealing  | O               | -               |
| Area selection  | O               | -               |
| Called party:   | (see note 1)    | (see note 7)    |
| Called party SNA  | C (see note 2)  | -               |
| Called party SSI  | C (see note 2)  | M               |
| Called party extension  | C (see note 2)  | M               |
| External subscriber number  | O (see note 1)  | -               |
| Received address type   | -               | O               |
| Calling party:  | - (see note 3)  | (see note 9)    |
| Calling party SSI   | -               | C (see note 8)  |
| Calling party extension   | -               | C (see note 8)  |
| External subscriber number (calling party)  | -               | O (see note 9)  |
| Protocol identifier   | M               | M               |
| Delivery report request   | M               | M               |
| Service selection   | M               | -               |
| Short form report   | -               | M               |
| Storage/forward control   | M (see note 4)  | M (see note 4)  |
| Message reference handle  | M               | -               |
| Message reference   | -               | M               |
| Validity period   | M               | O               |
| Forward address:  | (see note 5)    | (see note 10)   |
| Forward address SNA   | C (see note 6)  |                 |
| Forward address SSI   | C (see note 6)  | C (see note 11) |
| Forward address extension   | C (see note 6)  | C (see note 11) |
| External subscriber number  | C (see note 6)  | C (see note 11) |
| Time stamp  | O (see note 12) | O (see note 12) |
| User data   | O               | O               |
| NOTE 1: This parameter shall indicate the address of the storing/forwarding entity to which the message is going for delivery to the destination entity.  |                 |                 |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.   |                 |                 |
| NOTE 3: Lower protocol layers will add the calling party identity.  |                 |                 |
| NOTE 4: This parameter shall indicate, if storage/forward control information is available.   |                 |                 |
| NOTE 5: This information element shall indicate the address of the final destination entity.  |                 |                 |
| NOTE 6: This parameter shall be present as defined by the forward address type identifier parameter.  |                 |                 |
| NOTE 7: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination entity.   |                 |                 |
| NOTE 8: This parameter shall be present as defined by the calling party type identifier parameter.  |                 |                 |
| NOTE 9: This parameter shall indicate the address of the storing/forwarding entity to which sent the message on behalf of the original source entity.   |                 |                 |
| NOTE 10: This parameter shall indicate the address of the original source entity.   |                 |                 |
| NOTE 11: This parameter shall be present as defined by the forward address type identifier parameter.   |                 |                 |
| NOTE 12: Availability of this parameter is protocol dependent refer to clauses 29.3.2.9 and 29.5.3.3. Normally the SwMI will add the timestamp to the message and the timestamp in the request is to support those cases where that service is not available in the SwMI. |                 |                 |

**TLSDS-REPORT request:** the primitive shall be used by the SDS-TL entity to send reports to a peer entity. Parameters indicate whether reporting is requested.

**TLSDS-REPORT indication:** the primitive shall be used by the SDS-TL to pass to the SDS-TL entity reports which have been received from a peer entity or generated by the SwMI or a storing/forwarding entity.

NOTE: A TLSDS-TNSDS-REPORT indication is used to convey local LLC generated reports about the PDU transfer result.

Table 29.3 gives parameters for the TLSDS TLSDS-REPORT primitives when no storing/forwarding entity is used.

**Table 29.3: Parameters for the TLSDS-REPORT primitive (no storing/forwarding)**

| Parameter   | Request               | Indication            |
|---|-----------------------|-----------------------|
| Access priority   | O                     | -                     |
| Traffic stealing  | O                     | -                     |
| Area selection  | O                     | -                     |
| Called party:   | See note 1            | See note 4            |
| Called party SNA  | C (see note 2)        | -                     |
| Called party SSI  | C (see note 2)        | M                     |
| Called party extension  | C (see notes 2 and 7) | M                     |
| External subscriber number (called party)   | O (see note 7)        | -                     |
| Calling party:  | See note 3            | See notes 5 and 6     |
| Calling party SSI   | -                     | M                     |
| Calling party extension   | -                     | M                     |
| External subscriber number (calling party)  | -                     | O (see notes 6 and 7) |
| Protocol identifier   | M (see note 7)        | M (see note 7)        |
| Acknowledgement required  | M (see note 8)        | M (see note 8)        |
| Delivery status   | M (see note 8)        | M (see note 8)        |
| Message reference handle  | -                     | O (see note 9)        |
| Message reference   | M                     | M                     |
| Time stamp  | O (see note 10)       | O (see note 10)       |
| User data   | O (see note 7)        | O (see note 7)        |
| <p>NOTE 1: This parameter shall indicate the address of the destination entity.</p> <p>NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.</p> <p>NOTE 3: Lower protocol layers will add the calling party identity.</p> <p>NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This parameter shall indicate the address of the destination entity.</p> <p>NOTE 5: This parameter shall value indicate "Calling party SSI" and "Calling party extension".</p> <p>NOTE 6: This parameter shall indicate the address of the source entity.</p> <p>NOTE 7: Not applicable for short reports.</p> <p>NOTE 8: For short reports these parameters are set to default values locally or may have a limited range of values.</p> <p>NOTE 9: This parameter shall be used in the first TLSDS-REPORT indication to a TLSDS-TRANSFER request.</p> <p>NOTE 10: Availability of this parameter is protocol dependent refer to clauses 29.3.2.9 and 29.5.3.3. Normally the SwMI will add the timestamp to the message and the timestamp in the request is to support those cases where that service is not available in the SwMI.</p> |                       |                       |

Table 29.4 gives parameters for the TLSDS-REPORT primitives, when a storing/forwarding entity is used.

**Table 29.4: Parameters for the TLSDS-REPORT primitive (storing/forwarding)**

| Parameter   | Request         | Indication        |
|---|-----------------|-------------------|
| Access priority   | O               | -                 |
| Traffic stealing  | O               | -                 |
| Area selection  | O               | -                 |
| Called party  | See note 1      | See note 4        |
| Called party SNA  | C (see note 2)  | -                 |
| Called party SSI  | C (see note 2)  | M                 |
| Called party extension  | C (see note 2)  | M                 |
| External subscriber number  | O (see note 1)  | -                 |
| Calling party   | See note 3      | See notes 5 and 6 |
| Calling party SSI   | -               | M                 |
| Calling party extension   | -               | M                 |
| External subscriber number (calling party)  | -               | O (see note 6)    |
| Protocol identifier   | M               | M                 |
| Acknowledgement required  | M               | M                 |
| Delivery status   | M               | M                 |
| Storage/forward control   | M (see note 13) | M (see note 13)   |
| Message reference handle  | -               | O (see note 7)    |
| Message reference   | M               | M                 |
| Validity period   | M               | O                 |
| Forward address:  | See note 8      | See note 10       |
| Forward address SNA   | C (see note 9)  |                   |
| Forward address SSI   | C (see note 9)  | C (see note 11)   |
| Forward address extension   | C (see note 9)  | C (see note 11)   |
| External subscriber number  | C (see note 9)  | C (see note 11)   |
| Time stamp  | O (see note 12) | O (see note 12)   |
| User data   | O               | O                 |
| NOTE 1: This parameter shall indicate the address of the storing/forwarding entity which sent the reported message on behalf of the original source entity.   |                 |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.   |                 |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.  |                 |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination entity.   |                 |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".  |                 |                   |
| NOTE 6: This parameter shall indicate the address of the storing/forwarding entity which sent the TLSDS-REPORT indication on behalf of the original destination entity.   |                 |                   |
| NOTE 7: This parameter shall be used in the first TLSDS-REPORT indication to a TLSDS-TRANSFER request.  |                 |                   |
| NOTE 8: This information element shall indicate the address of the final destination entity.  |                 |                   |
| NOTE 9: This parameter shall be present as defined by the forward address type identifier parameter.  |                 |                   |
| NOTE 10: This parameter shall indicate the address of the original source entity.   |                 |                   |
| NOTE 11: This parameter shall be present as defined by the forward address type identifier parameter.   |                 |                   |
| NOTE 12: Availability of this parameter is protocol dependent refer to clauses 29.3.2.9 and 29.5.3.3. Normally the SwMI will add the timestamp to the message and the timestamp in the request is to support those cases where that service is not available in the SwMI. |                 |                   |
| NOTE 13: This parameter shall indicate storing/forwarding.  |                 |                   |

**TLSDS-ACK request:** the primitive shall be used by the SDS-TL entity to acknowledge reports from a peer entity to the next SDS-TL aware node. The TLSDS-ACK request is used to acknowledge unsolicited reports (consumed message) or reports which may have been stored in the SwMI or at a storing/forwarding entity.

**TLSDS- ACK indication:** the primitive shall be used by the SDS-TL to pass to the SDS-TL entity report acknowledgements which have been received from a peer entity or generated by the SwMI or a storing/forwarding entity.

Table 29.55 gives parameters for the TLSDS-ACK primitives when no storing/forwarding entity is used.

**Table 29.5: Parameters for the TLSDS-ACK primitive (no storing/forwarding)**

| Parameter   | Request        | Indication        |
|---|----------------|-------------------|
| Access priority   | O              | -                 |
| Traffic stealing  | O              | -                 |
| Area selection  | O              | -                 |
| Called party  | See note 1     | See note 4        |
| Called party SNA  | C (see note 2) | -                 |
| Called party SSI  | C (see note 2) | M                 |
| Called party extension  | C (see note 2) | M                 |
| External subscriber number (called party)   | O              | -                 |
| Calling party   | See note 3     | See notes 5 and 6 |
| Calling party SSI   | -              | M                 |
| Calling party extension   | -              | M                 |
| External subscriber number (calling party)  | -              | O (see note 6)    |
| Protocol identifier   | M              | M                 |
| Delivery status   | M              | M                 |
| Message reference   | M              | M                 |
| NOTE 1: This parameter shall indicate the address of the destination entity.  |                |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.   |                |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.  |                |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This parameter shall indicate the address of the destination entity. |                |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".  |                |                   |
| NOTE 6: This parameter shall indicate the address of the source entity.   |                |                   |

Table 29.56 gives parameters for the TLSDS-ACK primitives, when a storing/forwarding entity is used.

**Table 29.6: Parameters for the TLSDS-ACK primitive (storing/forwarding)**

| Parameter   | Request        | Indication        |
|---|----------------|-------------------|
| Access priority   | O              | -                 |
| Traffic stealing  | O              | -                 |
| Area selection  | O              | -                 |
| Called party:   | See note 1     | See note 4        |
| Called party SNA  | C (see note 2) | -                 |
| Called party SSI  | C (see note 2) | M                 |
| Called party extension  | C (see note 2) | M                 |
| External subscriber number  | O (see note 1) | -                 |
| Calling party:  | See note 3     | See notes 5 and 6 |
| Calling party SSI   | -              | M                 |
| Calling party extension   | -              | M                 |
| External subscriber number (calling party)  | -              | O (see note 6)    |
| Protocol identifier   | M              | M                 |
| Delivery status   | M              | M                 |
| Message reference   | M              | M                 |
| NOTE 1: This parameter shall indicate the address of the storing/forwarding entity from which the acknowledged report message was received.       |                |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.   |                |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.  |                |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination entity. |                |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".  |                |                   |
| NOTE 6: This parameter shall indicate the address of the storing/forwarding entity to which the acknowledged report message was originally sent.  |                |                   |

**TLSDS-TNSDS-REPORT indication:** the primitive shall be used to indicate whether a TLSDS-ACK request, a TLSDS-TRANSFER request, a TLSDS-REPORT request, or a TLSDS-UNITDATA request has been either transmitted successfully or the transmission has failed. Refer to clause 13.3.2.2 for primitive contents.

**TLSDS-UNITDATA request:** the primitive shall be used to send user defined data-4 to a peer entity, when not using the SDS-TL data transfer services. Refer to clause 13.3.2.2 for primitive contents. The user defined data-4 parameter shall contain the protocol identifier parameter and the actual user data.

**TLSDS-UNITDATA indication:** the primitive shall be used to receive user defined data-4 from a peer entity, when not using the SDS-TL data transfer services. Refer to clause 13.3.2.2 for primitive contents. The user defined data-4 parameter shall contain the protocol identifier parameter and the actual user data.

### 29.2.3 SDS-TL primitives' parameters

Parameter values shall be as defined in this clause and in clause 13.3.3 for the basic SDS.

Acknowledgement required =

- no further acknowledgements required for this message; or
- acknowledgement required for this message.

Delivery report request =

- no delivery report requested;
- message received report requested;
- message consumed report requested; or
- message received and consumed report requested.

Delivery status =

- Refer to clause 29.4.3.2 for further details.

Forward address =

- SNA;
- SSI;
- SSI and address extension; or
- external subscriber number.

Message reference =

- 0 to 255.

Message reference handle =

- 0 to 255, a local handle to the actual message reference. The mapping between a message reference and a message reference handle is a local issue and outside the scope of the present document.

Protocol identifier =

- Protocol which is invoked by the primitive, refer to clause 29.4.3.9.

Service selection =

- individual service; or
- group or individual service.

Short form report =

- Use of short form report is recommended (during the validity period of the message);
- Only standard report allowed.

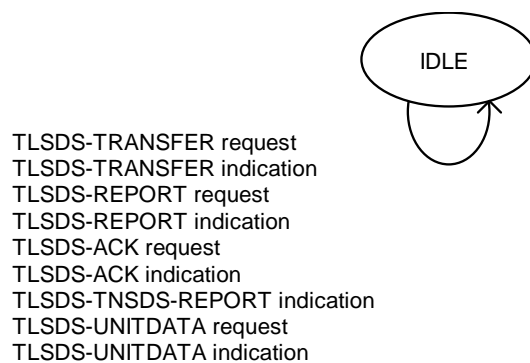

Storage/forward control =

- Storage/forward control information not available; or
- Storage/forward control information available.

Validity period =

- one try, no extended validity period i.e. any other value indicates that storage is allowed;
- 10 s to 2 weeks; or
- network determined.

## 29.2.4 State description

**Figure 29.2: State transition diagram**

The IDLE state represents the initial and final state of all the primitive sequences as defined in figure 29.2. Note that this state transition diagram represents the state transfer of the SDS-TL entity, not the application using SDS-TL. The state diagram of such applications is outside the scope of the present document.

## 29.3 Protocol description

### 29.3.1 Addressing mechanism

When sending an SDS-TL message, the addressing to the final destination is achieved in a number of different ways depending whether or not a storing/forwarding entity function is used. Following destination addresses are specified in an SDS-TL message from MS to SwMI:

- Called party address (destination or next node) in U-SDS-DATA PDU part;
- External subscriber number (destination or next node) in U-SDS-DATA PDU part;

NOTE 1: The previous addresses can be used for all of the SDS-TL PDUs.

- Forward address (destination) in SDS-TRANSFER PDU part;
- Forward address (original source) in the SDS-REPORT PDU; and
- The used MAC layer address implies the source address.

The following source addresses are specified in an SDS-TL message from SwMI to MS:

- calling party address (source or previous node) in D-SDS-DATA PDU part;
- external subscriber number (source or previous node) in D-SDS-DATA PDU part;

NOTE 2: The previous addresses can be used for all of the SDS-TL PDUs.

- forward address (source) in SDS-TRANSFER PDU part;
- forward address (original destination) in the SDS-REPORT PDU; and
- the used MAC layer address implies the destination address.

The called party address is always present and always indicates the next node address (final destination, storing/forwarding entity or gateway and external subscriber number).

The external subscriber number is an optional information element that allows sending of up to 24 digits in e.g. an ISDN address. When used in the U-SDS-DATA PDU it amends the called party address (PDU next destination). When used in the D-SDS-DATA PDU it amends the calling party address (PDU latest source). When used in the forward address it is the final destination or original source address.

The forward address is an optional information element that indicates the final destination or original source TETRA address. It may be an SSI, SSI and address extension (TSI) or external subscriber number.

The calling party address is always present and always indicates the previous node address (final destination, storing/forwarding entity or gateway and external subscriber number). In case no forward address is used, the called party address (optionally amended by the external subscriber number) indicates the final destination and the calling party address (optionally amended by the external subscriber number) indicates the source. The use of the addresses in this case is shown in table 29.7. The addressing of having the final destination/original source in external subscriber number information element of the U-SDS DATA PDU and gateway address in the called party address information element is supported by this addressing scenario.

In case the forward address is used, this address indicates the true destination or original source, and the called or calling party address in the SDS-DATA PDU (optionally amended by the external subscriber number in U-SDS DATA or D-SDS DATA PDU) indicates the next or previous node address. The use of the addresses in this case for MS to MS communication is shown in table 29.8.

The use of the addresses in the case of communication via a gateway to a user addressed by the external subscriber number is shown in table 29.9. In that table, user 2 is addressed by the external subscriber number in the forward address field or in the U-SDS-DATA. A target MS (using an MS-ISDN) may be addressed using any of the following combinations:

- via a gateway by indicating the gateway SSI in the called party address and the target in the external subscriber number of the U-SDS-DATA with no forward address (the SSI is the gateway address); or
- via a gateway by indicating the gateway SSI in the called party address and an external subscriber number in U-SDS-DATA (in which case the external subscriber number identifies some gateway), with the final target in the external subscriber number of the forward address field.

The SwMI may control usage of the forward address for storing/forwarding entity purpose in case of CA by the "extended services broadcast" information element in SYSINFO and SYSINFO-Q broadcasts, refer to clause 21.4.4.1 and 21.4.4.1a or in case of DA by the "extended DA services broadcast" information element in SYSINFO-DA broadcast, refer to clause 21.4.4.1b. The SDS-TL addressing method information element values has the meaning, when using the storing/forwarding entity functionality:

- "Service centre addressing preferred" defines that the MS shall address the SDS-TL transport service PDUs so it contains the destination of the PDU in the forward address information element and the address of the storing/forwarding entity in the called party or in the called party and external subscriber number information element of the SDS DATA PDU. Exceptions to that rule are:
  - MS does not know the storing/forwarding entity (service centre) address in which case MS may attempt to send the PDU without the forward address directly to the destination. In this scenario, the SwMI may either support the addressing types as defined by "Never use service centre addressing" or the SwMI may reject the message;

NOTE 3: The SwMI may support SDS-TL transport services and use a default storing/forwarding entity or may not support SDS-TL transport services but behave as a transparent SwMI.

- MS is sending the message to a user of another SwMI in which case it may or may not use a forward address. How MS knows whether the other SwMI supports forwards addressing and how it knows the storing/forwarding entity address of the other SwMI and the behaviour of the other SwMI are outside the scope of the present document.
- "Never use service centre addressing" defines that the MS shall address the SDS-TL transport service PDUs directly to the destination of the PDU. The message should be addressed directly to the destination, and the forward address shall not be used. If storage is required (a SwMI may support storage without requiring a storing/forwarding entity (service centre) to be addressed), the "storage/forward control" bit shall set to "storage/forward control information available" and the forward address type shall be set to "no forward address present". Otherwise, the "storage/forward control" bit shall be set to "storage/forward control information not available". Exception to the forward addressing rule is:
  - MS is sending the message to a user of another SwMI in which case it may or may not use a forward address. How MS knows whether the other SwMI supports forwards addressing and how it knows the storing/forwarding address of the other SwMI and the behaviour of the other SwMI are outside the scope of the present document.

NOTE 4: The broadcast value "never use service centre addressing" normally indicates that the SwMI does not support storing/forwarding entity functionality.

- "MS choice to use service centre addressing" defines that the MS may select the addressing it applies. The SwMI supports both addressing with and without a storing/forwarding entity (service centre). MS should use PDUs without a forward address when it is not using the transport services (storing/forwarding entity) of the SwMI.

The SYSINFO, SYSINFO-Q and SYSINFO-DA broadcast information shall control the addressing of the SDS-TRANSFER PDU. The addressing of the SDS-REPORT PDU shall be the same as used in the corresponding SDS-TRANSFER PDU and the SDS-REPORT PDU should use the same storing/forwarding entity (service centre) as used in the original received SDS-TRANSFER PDU so that also the storing/forwarding entity knows that the SDS-TRANSFER PDU has been received. This also implies that the SDS-SHORT-REPORT shall be send to the storing/forwarding entity, if it is allowed to send a SDS-SHORT-REPORT. It shall be emphasized that a storing/forwarding entity shall only request a short report, if it can differentiate between the replies.

**Table 29.7: MS1 to MS2 transparent**

| PDU and hop   | Source address in the SDS DATA PDU | Destination address in the SDS DATA PDU | Forward address | Remark             |
|---|------------------------------------|---|-----------------|--------------------|
| SDS-TRANSFER MS1 → MS2  | MS1                                | MS2                                     | -               | No forward address |
| SDS-REPORT MS2 → MS1 (received)   | MS2                                | MS1                                     | -               | No forward address |
| SDS-REPORT MS2 → MS1 (consumed)   | MS2                                | MS1                                     | -               | No forward address |
| SDS-ACK MS1 → MS2 (consumed-ack)  | MS1                                | MS2                                     | N/A             |                    |
| NOTE: The destination address can be any addressing type of the SDS-DATA PDU. |                                    |   |                 |                    |

Table 29.8: MS1 to MS2 using forward address

| PDU and hop  | Source address in the SDS DATA PDU | Destination address in the SDS DATA PDU | Forward address      | Remark   |
|--|------------------------------------|---|----------------------|--|
| SDS-TRANSFER MS1 → SwMI  | MS1                                | SwMI                                    | MS2,<br>(see note 1) | Forward address indicates the true destination   |
| SDS-REPORT SwMI → MS1<br>(delivered/stored)  | SwMI                               | MS1                                     | MS2,<br>(see note 3) | If present, forward address indicates the destination of the original SDS-TRANSFER PDU |
| SDS-TRANSFER SwMI → MS2  | SwMI                               | MS2                                     | MS1                  | Forward address indicates the true source  |
| SDS-REPORT MS2 → SwMI<br>(received)  | MS2                                | SwMI                                    | MS1,<br>(see note 2) | Forward address indicates the original source of the reported SDS-TRANSFER PDU         |
| SDS-REPORT SwMI → MS1<br>(received)  | SwMI                               | MS1                                     | MS2,<br>(see note 3) | If present, forward address indicates the destination of the original SDS-TRANSFER PDU |
| SDS-ACK MS1 → SwMI<br>(received-ack)   | MS1                                | SwMI                                    | N/A                  |  |
| SDS-REPORT MS2 → SwMI<br>(consumed)  | MS2                                | SwMI                                    | MS1,<br>(see note 2) | Forward address indicates the original source of the reported SDS-TRANSFER PDU         |
| SDS-ACK SwMI → MS2<br>(consumed-ack)   | SwMI                               | MS2                                     | N/A                  |  |
| SDS-REPORT SwMI → MS1<br>(consumed)  | SwMI                               | MS1                                     | MS2,<br>(see note 3) | If present, forward address indicates the destination of the original SDS-TRANSFER PDU |
| SDS-ACK MS1 → SwMI<br>(consumed-ack)   | MS1                                | SwMI                                    | N/A                  |  |
| NOTE 1: The use of the Forward address for the storing/forwarding entity functionality is controlled by the "extended services broadcast" information element in SYSINFO and SYSINFO-Q broadcasts, refer to clauses 21.4.4.1 and 21.4.4.1a and by the "extended DA services broadcast" information element in SYSINFO-DA broadcast, refer to clause 21.4.4.1b. |                                    |   |                      |  |
| NOTE 2: The forward address is used because the original SDS-TRANSFER PDU to MS2 contained a forward address.  |                                    |   |                      |  |
| NOTE 3: The forward address is optional.   |                                    |   |                      |  |

Table 29.9: MS1 to MS2/user 2 using forward address via a gateway

| PDU and hop  | Source address in the SDS DATA PDU | Destination address in the SDS DATA PDU             | Forward address          | Remark   |
|--|------------------------------------|---|--------------------------|--|
| SDS-TRANSFER MS1 → SwMI  | MS1                                | SwMI/SwMI with User 2 in external subscriber number | user 2/N/A, (see note 1) | Forward address may indicate the true destination or the true destination may be in the external subscriber number field |
| SDS-REPORT SwMI → MS1 (delivered/stored)   | SwMI                               | MS1   | MS2, (see note 3)        | If present, forward address indicates the destination of the original SDS-TRANSFER PDU                                   |
| SDS-TRANSFER SwMI → MS2/user 2   | SwMI                               | MS2/user 2  | MS1                      | Forward address indicates the true source  |
| SDS-REPORT MS2/user 2 → SwMI (received)  | MS2/user 2                         | SwMI  | MS1, (see note 2)        | Forward address indicates the source of the reported SDS-TRANSFER PDU  |
| SDS-REPORT SwMI → MS1 (received)   | SwMI                               | MS1   | MS2/user 2, (see note 3) | If present, forward address indicates the destination of the original SDS-TRANSFER PDU                                   |
| SDS-ACK MS1 → SwMI (received-ack)  | MS1                                | SwMI  | N/A                      |  |
| SDS-REPORT MS2/user 2 → SwMI (consumed)  | MS2/user 2                         | SwMI  | MS1, (see note 2)        | Forward address indicates the source of the reported SDS-TRANSFER PDU  |
| SDS-ACK SwMI → MS2/user 2 (consumed-ack)   | SwMI                               | MS2/user 2  | N/A                      |  |
| SDS-REPORT SwMI → MS1 (consumed)   | SwMI                               | MS1   | MS2/user 2, (see note 3) | If present, forward address indicates the destination of the original SDS-TRANSFER PDU                                   |
| SDS-ACK MS1 → SwMI (consumed-ack)  | MS1                                | SwMI  | N/A                      |  |
| NOTE 1: The use of the Forward address for the storing/forwarding entity functionality is controlled by the "extended services broadcast" information element in SYSINFO and SYSINFO-Q broadcasts, refer to clauses 21.4.4.1 and 21.4.4.1a and by the "extended DA services broadcast" information element in SYSINFO-DA broadcast, refer to clause 21.4.4.1b. |                                    |   |                          |  |
| NOTE 2: The forward address is used because the original SDS-TRANSFER PDU to MS2/user 2 gateway contained a forward address. In the case of a TETRA gateway, the PDU exchange is internal to SwMI and may not be explicit.   |                                    |   |                          |  |
| NOTE 3: The forward address is optional.   |                                    |   |                          |  |

"MS1", "MS2", and "SwMI" here denotes the address of the originating and destination MS, and the address of the storing/forwarding entity. The "SwMI" address may comprise a gateway address or a gateway address and an external subscriber address.

## 29.3.2 Description of protocol elements

### 29.3.2.0 General

The clauses 29.3.2.1 to 29.3.2.10 describe the key aspects of the SDS-TL protocol information elements.

### 29.3.2.1 Protocol identifier

Each SDS-DATA type 4 PDU which is sent shall contain a protocol identifier. The protocol identifier shall indicate to the addressed entity application which type of application protocol is using the SDS service. The present document currently defines a number of protocol identifiers to provide e.g. OTAK, text messaging, location system, WAP, WCMP, end-to-end encrypted message, immediate text messaging, M-DMO, PIN-authentication, LIP and message with user data header application services. A number of reserved protocol identifiers allow additional standard data services to be added in the future. There is also a range of protocol identifiers available for user definition. The value of the protocol identifier determines whether the SDS-TL (data transfer service) protocol elements and the protocol defined in the present document shall be used (see table 29.21).

### 29.3.2.2 End-to-end acknowledgement types

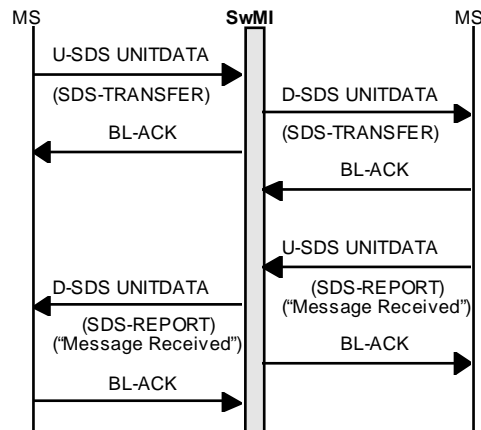

The main objective of the SDS-TL protocol, as well as providing a mechanism to indicate the type of application using the service, is to provide a means for end-to-end acknowledgement of messages; this mechanism is not provided by the TETRA SDS service as defined in clause 14. SDS-TL provides two types of end-to-end acknowledgement which are distinct from the layer 2 acknowledgement procedures already provided by the LLC. The type of end-to-end acknowledgement which shall apply to a message transfer is set by the originator using the "Delivery report request" information element. These end-to-end acknowledgement types are described below:

- Layer 2 acknowledgement only i.e. no end-to-end acknowledgement.
- The LLC provides an acknowledged service for PDUs transferred point-to-point over a single hop i.e. MS to SwMI or SwMI to MS. This acknowledgement confirms to the sender that the layer 3 PDU was received correctly by the receiver. However, the LLC acknowledgement does not imply that the receiving end has yet examined the contents of the PDU. Figure 29.3 illustrates the layer 2 acknowledgement.

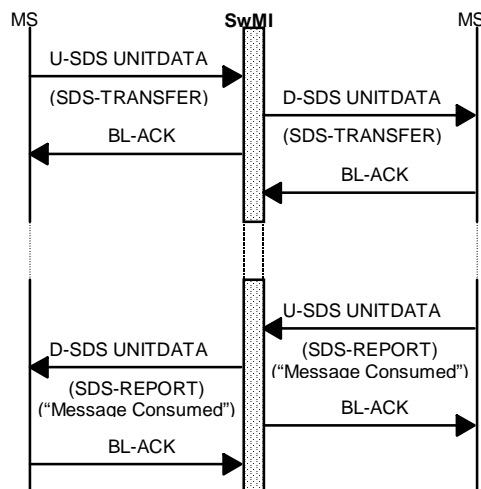

**Figure 29.3: Layer 2 Acknowledgement**

- Message received:
  - The "message received" acknowledgement is sent using the SDS-TL layer to indicate that a message sent by an MS has been successfully received by the destination. This acknowledgement message is an SDS-TL PDU which is generated by the MS after it has decoded the SDS-TL PDU received from the originator. (This is in contrast to a layer 2 acknowledgement which is sent before the incoming PDU has been decoded.) Therefore, this acknowledgement is sent by the destination back to the originator and simply relayed by the SwMI. This type of acknowledgement may be used for point-to-point and point-to-multipoint transfer although care should be used for point-to-multipoint transfer where large group sizes may result in large amounts of air interface traffic for acknowledgements. Figure 29.4 illustrates the "message received" end-to-end acknowledgement.

**Figure 29.4: "Message received" end-to-end acknowledgement**

- Message consumed:
  - The "message consumed" acknowledgement is sent using the SDS-TL layer to indicate that a message sent by an MS has been consumed by the destination. Message consumption occurs after the SDS-TL PDU has been received and decoded by the destination application and refers to the point where the message is actually used by the application. Message consumption is application dependent and is specified in clause 29.3.2.2 for each of the standard applications covered by the present document. Once an application has consumed a message, it may use the SDS-TL protocol to convey this back to the originator. Figure 29.5 illustrates the "message consumed" end-to-end acknowledgement. Note that this figure does not show any "message received" acknowledgement which may be sent in between the message transfer and the "message consumed" acknowledgement.

**Figure 29.5: "Message consumed" end-to-end acknowledgement**

For the acknowledgement types "message received" and "message consumed", the SDS-TL protocol shall allow the originator of a message to specify which type of acknowledgement is desired from the destination. An application shall then make this choice depending on the type of data being delivered and whether the transfer is point-to-point or multipoint. SDS-TL simply provides an application with a standardized mechanism to convey these acknowledgement reports.

The criteria of message consumption depend on the application. Message consumption criteria for each of the applications covered by the present document are defined below:

- Text Messaging:
  - Message consumption for the text messaging application shall be when the application displays the text message to the user. Usually, this requires an action by the user to read the message which has been received and stored in the MS.

- Location system:
  - The location system protocol does not have a clear concept of message consumption. Whether message consumption is applicable or not depends on the application using the protocol.
- Simple Text Messaging:
  - The simple text messaging protocol does not use the SDS-TL data transfer protocol. This means that no end-to-end acknowledgement is available in simple text messaging.
- Simple location system:
  - The simple location system protocol does not use the SDS-TL data transfer protocol. This means that no end-to-end acknowledgement is available in simple location systems.
- AGNSS:
  - The AGNSS protocol does not have a clear concept of message consumption. Whether message consumption is applicable or not depends on the application using the protocol. The sending of broadcast messages using SDS TL is defined in clause 29.3.3.8.2, explicitly defining that no acknowledgements shall be used when using SDS-TL for system broadcast messages
- Simple AGNSS:
  - The simple AGNSS protocol does not use the SDS-TL data transfer protocol. This means that no end-to-end acknowledgement is available in simple GNSS.
- Other standardized protocols using SDS:
  - The other standardized protocols using SDS may or may not use the SDS-TL data transfer protocol. Other SDS-TL protocols may be standardized in the future and the meaning of message consumption defined in the present document. Alternatively, user applications may use SDS-TL where the meaning of message consumption is specific to that application.

### 29.3.2.3 Service selection/short form report

Each uplink SDS-TRANSFER PDU that is sent shall contain a service selection information element. The service selection information element is used to indicate whether the message is allowed to be sent to a group address or not. This is useful in a text messaging application where the user may be allowed to enter the destination address manually. In this case, the sending MS has no way of informing the user that this message will be sent to multiple targets. This could lead to substantial resource waste if, by accident, a message with non-zero delivery report requests is sent to a large group of MSs.

To prevent this, the service selection information element forces the originating user to make an explicit choice that the message is allowed to be sent to a group. The network is then able to reject messages addressed to a group, but with the service selection information element set to "Individual service".

The short form report information element on downlink SDS-TRANSFER PDUs inform the destination user whether it should use or is not allowed to use short form reporting mechanism.

### 29.3.2.4 Storage/forward control

Each SDS-TRANSFER PDU that is sent shall contain a "storage/forward control" information element. The "storage/forward control" information element is used to indicate whether the SwMI is allowed to store the message longer than needed for ordinary processing and whether a storing/forwarding entity is specified. If indicated by this information element, the SwMI or a storing/forwarding entity, may store the message for later delivery attempts if the destination is not available.

The criterion for attempting to deliver the message again is outside the scope of the present document.

### 29.3.2.5 Message reference

Each SDS-TL data transfer service PDU that is sent shall contain a message reference information element. This message reference shall be used in the end-to-end acknowledgement back from the destination, or in reports from the SwMI or storing/forwarding entity, to indicate to the originator which message is being acknowledged. The message reference shall also be used in negative acknowledgements.

The originator should choose a different message reference for each new message sent regardless of the destination, if it requests a report. If an acknowledgement is outstanding, regardless of the destination, the corresponding message reference should not be re-used. In the source entity, the validity of the message reference of a message after an extended time after sending the message and expiry of the selected validity period, if any, but without receiving requested reports is outside the scope of the present document.

By following this use of the message reference, the combination of the message reference, and source address (ITSI) shall uniquely identify each message being transported by a TETRA network.

The storing/forwarding entity or SwMI shall not modify the value of the message reference.

NOTE 1: SwMI may not include the forward address into all reports notably error reports in which case the storing/forwarding entity (service centre) address may be the only destination related address in the report. Consequently, the message reference with the storing/forwarding entity address is the only linkage to the sent message and SDS-TRANSFER PDU source entity should choose to use different message reference for each message independently of the destination address.

NOTE 2: In the case of a gateway to another telecommunication network the source or destination address as appropriate is the TETRA address of that gateway.

In the case of short report the message reference may be the only valid identifier of the acknowledgement.

### 29.3.2.6 Validity period

If storage of the message is allowed, each SDS-TRANSFER or SDS-REPORT PDU which is sent by an MS shall contain a "validity period" information element. This information element indicates how long the message should be held by the SwMI in the event that the message cannot be delivered to the destination. A destination MS may be unavailable due to being out of coverage or switched off. If the SwMI holds a message, it should attempt to deliver the message until the validity period expires after which the message is discarded and an error report may be sent back to the originating MS.

Note that the SwMI may not support a storage mechanism or it may limit the duration of the validity period in which case it should return an error report indicating either that the message has not been delivered and that the SwMI will not store the message or that the validity period has terminated.

If the validity period is set to "0" or the element is missing then the SwMI should not store the message for an extended period, if it cannot be delivered.

### 29.3.2.7 Forward address

If storage/forward control information is available, each SDS-TRANSFER which is sent by an MS may contain a "forward address" information element. The MS uses "forward address" information element when the layer 3 destination address points to a network service entity (e.g., a service centre) instead of the final destination. The use of such a network service entity can be many. The network service entity can:

- identify the storing/forwarding entity for a message in a store and forward service;
- identify some other value adding network device.

The "forward address" is somewhat similar to the layer 3 information element "external subscriber number" but is totally independent of it.

When used in the context of providing an addressed storing/forwarding entity for text messages, the forward address is used on the uplink is to inform the network service entity of the true destination, and used on the downlink is to inform the destination of the true source. If no forward address is present, the true source and destination are the addresses present in the CMCE SDS PDU information elements except in certain error cases, refer to clause 29.3.3.

### 29.3.2.8 Data coding scheme

The data coding scheme information element shall indicate to the destination application which type of data coding is being used by the application according to the type of protocol identifier. For example, the text messaging application may use a 7-bit character coding alphabet or a 16-bit alphabet depending on the needs of the particular application. The text coding scheme defines some standard alphabets with some reserved values available for user definition and future standard coding schemes. The location system coding scheme does the same for location information.

This information element is present in protocols where data coding scheme is of importance. The information element is thus not part of the SDS-TL protocol, but rather a higher layer addition for specific protocol identifiers (see table 29.21 and clause 29.5).

### 29.3.2.9 Time stamp

The time stamp information element shall indicate the approximate creation time of the message. The information element is added to a message by the SwMI to allow the destination to evaluate the age of the message. The SwMI decides whether to add the time stamp or not. How this decision is made is outside the scope of the present document, but can e.g. be based on the capabilities of the SwMI or on provisioning arrangements.

In some situations the addition of the time stamp can cause the maximum allowed message length to be exceeded. The SwMI should not add the time stamp in these circumstances, regardless of provisioning arrangements or other aspects.

NOTE: The time stamps added by the SwMI(s) are not guaranteed to be monotonically increasing.

This information element is present in protocols where storing/forwarding entity is used and where time stamping is of importance. The information element is thus not part of the layer 4 SDS-TL protocol, but rather a higher layer addition for specific protocol identifiers (see clauses 29.4.3.9 and 29.5).

Table 29.40 defines possibilities for timeframes of the time stamp. The time stamp should use Universal Time Co-ordinated (UTC time) as the time frame. That is in line with the TETRA network time usage, refer to clause 18.5.24 although the time encoding is different.

Applications may convert the UTC time to the local time and take into account summer time as applicable for presentation to the human users.

### 29.3.2.10 User data length

The length of the "User data" information element (the payload) is derived from the length field in the SDS DATA PDU header. This field indicates the number of bits in the SDS payload, including the (known) length of the SDS-TL header.

For applications, such as simple text messaging, the number of bits in the "User data" information element together with the "Text coding scheme" information element can then be used to derive the number of characters in a message. For example, if the layer 3 SDS type 4 header specifies a length of 86 bits and the coding scheme is 7-bit ASCII, then the "User data" information element contains 70 bits of characters of 7 bits after removal of the SDS-TL header (protocol identifier and text coding scheme), indicating that there are 10 characters present.

## 29.3.3 Procedures

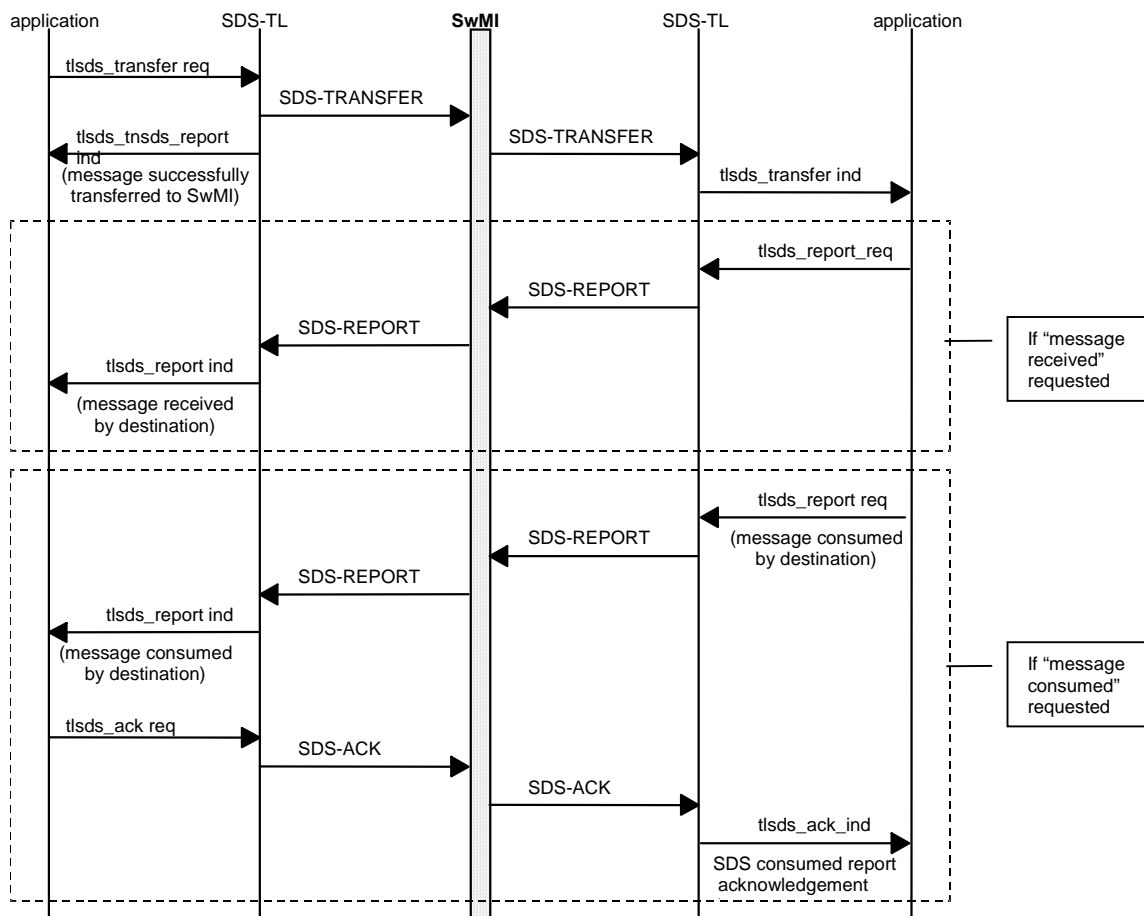

### 29.3.3.1 General description

Figure 29.6 shows the protocol sequence for a message transfer from an MS to a destination MS (or group of MSs), where both the received and consumed end-to-end acknowledgements are requested. The SDS-TRANSFER is carried by U/D-SDS-DATA PDUs with an end-to-end acknowledgement being sent by the application of the destination MS on receipt of the message. The acknowledgement is conveyed using SDS-REPORT which is also carried by U/D-SDS-DATA PDUs. On consumption of the message by the application e.g. the user reading a text message, a second end-to-end acknowledgement (SDS-REPORT PDU) is sent by the destination back to the originating MS. This second acknowledgement can almost be considered a second service invocation: the linkage to the original transfer is the message reference and the addresses of the MSs, refer to table 29.7. Because of this, application may request the SDS-REPORT PDU be acknowledged as well. This acknowledgement shall be conveyed using SDS-ACK PDU. The SDS-ACK PDU is not an end-to-end acknowledgement, but an acknowledgement to the next SDS-TL aware node. This next node may or may not be the final destination.

NOTE 1: If the destination consumes the message before the message received report is sent the destination may only send back the consumed report.

If the end-to-end mechanisms are used without a storing/forwarding entity, the application should define procedures for handling of retries in case of missing acknowledgements. These procedures are application specific and outside the scope of the present document.

The protocol used without a storing/forwarding entity is used transparently to the SwMI, which only acts as a layer 3 network. This means that part of this protocol sequence can be left out by the application: the SwMI need not to be aware of this. In particular, the SDS-TL protocol allows the application to specify which kind of acknowledgement is requested by the message source. If storage is not allowed, the SwMI should normally act transparently. The SwMI may though for example inject a forwarding entity, if the SwMI wants to exercise further control over, how a service is provided.

NOTE: The `tlsds_tnsds` report (message successfully transferred to SwMI) as the first response to the `tlsds_transfer req` is an example of lower layer reports (BL-ACK PDU) and is not repeated for all requests.

**Figure 29.6: SDS message transfer with end-to-end acknowledgement, SwMI transparent**

If the SwMI stores the message for later delivery, the SwMI storing/forwarding entity may inform the originating MS by sending an SDS-REPORT PDU. This is shown in figure 29.7. This informs the originating MS that the message has been received by the storing/forwarding entity service: note that this message should be sent if either the "message received" or "message consumed" delivery reports are requested. On consumption of the message by the application e.g. the user reading a text message, a second end-to-end acknowledgement is sent by the destination back to the originating MS, again through the storing/forwarding entity service.

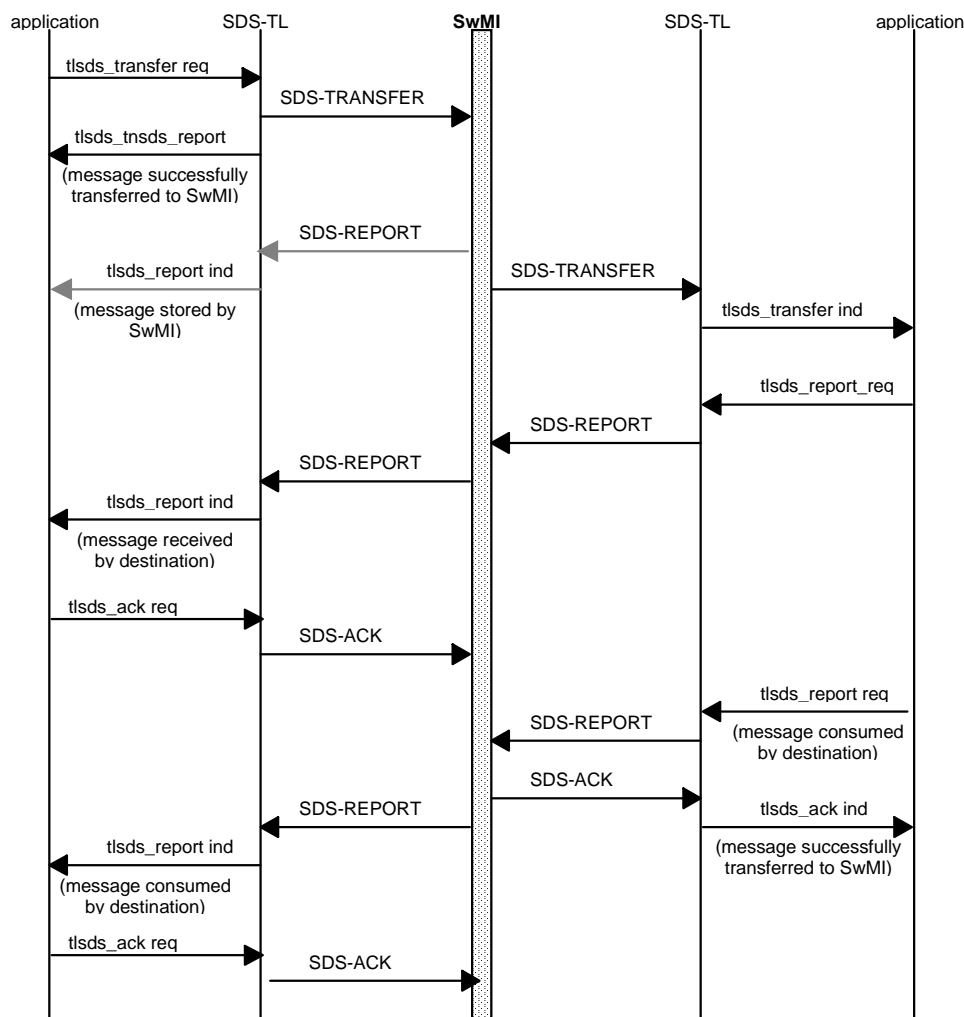

NOTE 2: In figures 29.6 to 29.8 texts in brackets next to service primitives indicate a completion of an action not a service primitive parameter value.

Note that the protocol sequence changes when the SwMI supports storing/forwarding entity. First, the sequence of messages changes because of the "intelligent" part resident in the SwMI. Secondly, one additional layer 4 acknowledgement may be needed: the "message received" acknowledge back to source shall, if requested, be acknowledged. However, even if storing/forwarding entity is supported in the SwMI and allowed by the message source, the protocol sequence can be the same as in the transparent case: if the SwMI delivers the message immediately, the "message stored by SwMI" may not be sent. Note that the SwMI now plays an active role, and leaving out part of this protocol sequence does require that the SwMI is aware of it.

If the "forward address" information element is used to provide storing/forwarding entity service via an addressed network service entity, the true destination address is only visible inside the initial SDS-TRANSFER PDU on the source (left) side of the SwMI (see figure 29.7). The same applies for the true source address on the destination (right) side. Seen from the SwMI perspective, the source and the destination will no longer communicate with each other, but both will communicate with the storing/forwarding entity.

When using store and forward the SwMI storing/forwarding entity may choose to modify the SDS-REPORT PDU to the source to get an additional SDS-ACK as shown in figure 29.7.

NOTE: The tlds\_tnsds report (message successfully transferred to SwMI) as the first response to the tlds transfer req is an example of lower layer reports (BL-ACK PDU) and is not repeated for all requests.

**Figure 29.7: SDS message transfer with end-to-end acknowledgement, SwMI does storing/forwarding**

When using storing/forwarding entity and requesting "message consumed" report but not "message received", the SwMI may choose to modify the SDS-TRANSFER PDU to the destination, as shown in figure 29.8. This will enable the SwMI to stop trying to deliver the message once it has reached the destination application.

NOTE 3: The SDS-ACK PDU is not an end-to-end acknowledge, but an acknowledge from the next node. This next node may or may not be the final destination.

The delivery report request indicates to the SwMI and the destination for the short message the type of reports which are required. These may be an acknowledgement from the destination when it receives the message or an acknowledgement from the destination when the message is consumed or both. For a text messaging application, message consumption would correspond to the user reading the received text message.

If message storage is allowed the validity period shall inform the SwMI how long the message is valid. The SwMI may use this information to store the message in the situation where the destination is not available. If the message cannot be delivered before the validity period expires, the SwMI shall discard the message and may report back to the sending MS that the message delivery was unsuccessful. The SwMI may modify the validity period for its own purposes when it send the message to the destination.

The destination MS may refer to the message also after the validity period by using the message reference. The message validity time in that sense is application dependent and is outside the scope of the present document.

The SwMI may control whether the destination may use short form report or not by the short form report information element in the SDS-TRANSFER PDU, refer to clause 29.4.3.10.

### 29.3.3.3 MS receiving a message

An incoming message is received as an SDS-TRANSFER PDU which is carried to an MS in D-SDS-DATA PDU. The information elements of SDS-TRANSFER PDU are as described in clause 29.4.2.4, table 29.14. The validity period information element may have been modified by the SwMI and may use the indicated value when choosing the report type or addressing, refer to clause 29.3.3.4.4.

When an MS SDS-TL entity receives an incoming message, it shall deliver it to the user application or interpret the message according to the protocol identifier and, if present, the data coding scheme. The delivery report request shall indicate to the MS or user application whether or not an acknowledgement for the message needs to be sent back to the SwMI. The procedures for sending an acknowledgement as a report are covered in clause 29.3.3.4. The report may also contain user data.

### 29.3.3.4 Sending an acknowledgement from the destination MS

#### 29.3.3.4.1 General

An MS receiving a message shall send an acknowledgement back to the SwMI according to the value of the "Delivery report request" information element. Note that the use of the term, "acknowledgement" in this sub-clause refers to an SDS-TL data transfer report and not to the layer 2 acknowledgements which may also be sent as part of the underlying SDS and LLC transport mechanism which are being used by SDS-TL. Also, the generator of the report should be the final destination: if the final destination is a host located on the PEI, then the report should be generated by the host connected to the PEI.

The SDS-REPORT PDU shall be used to send an acknowledgement back to the sender of the message. The "Message reference" information element shall be set to be equal to the message reference of the original received message to which the acknowledgement refers. The message reference and original source (destination of the SDS-REPORT PDU) address uniquely identifies a message so that the report can be matched to the SDS-TRANSFER PDU, which is acknowledged, in the SwMI. The message reference may be the only matching element to the SDS-TRANSFER PDU, which is acknowledged, in the originator entity as the use of the original destination address is optional. Refer to clause 29.3.1 on addressing and clause 29.3.2.5 on message reference.

Upon receiving an SDS-REPORT PDU, the SwMI should relay this PDU back to the originator of the SDS-TRANSFER PDU without other modification than required for addressing and validity period, which SwMI may modify. When storing/forwarding entity is supported, the SwMI may temporarily shield the originator from negative acknowledgements or modify the report (see clause 29.3.3.6.3); for example, if a memory capacity exceeded delivery status is returned from the target, the storing/forwarding entity may shield this report from the originator and retry sending the message at a later time within the validity period. The validity period in the SDS-REPORT PDU has no meaning to the destination of the SDS-REPORT PDU. The SwMI may use storing/forwarding entity service, if it is allowed in the SDS-REPORT PDU. Note that, as shown in figures 29.6 to 29.8, the application is responsible for sending acknowledgements using the TLSDS-REPORT request primitive in accordance with the parameters of the TLSDS-TRANSFER indication. The SDS-TL layer simply provides a transport mechanism and PDU definition for sending acknowledgements.

End-to-end acknowledgements may be requested for both point-to-point and point-to-multipoint message transfers; in the case of multipoint transfers an acknowledged service should be used with care due to the amount of air interface traffic which could be generated by a large group of MS sending acknowledgements back to the originator. It is recommended that point-to-multipoint transfer does not request end-to-end acknowledgement. In fact, the SwMI may modify a multi-point transfer (by modifying the "Delivery report request" information element to "No delivery report requested" and returning a report to the originator indicating "SDS sent to group, acknowledgements prevented") to prevent the destination MS group sending acknowledgements.

If an acknowledgement is requested for a point-to-multipoint transfer, the SDS message carrying the acknowledgement shall contain the individual address of each destination MS (not the group address) and the message reference of the original SDS-TRANSFER PDU. It is then the responsibility of the originating application to match the acknowledgements to the original sent message using the message reference.

The sender of the SDS-REPORT PDU may request the recipient to send an SDS-ACK PDU to acknowledge the reception of the SDS-REPORT PDU, refer to clauses 29.3.3.5 and 29.3.3.7.

**NOTE:** When the destination MS wishes to receive an SDS-ACK PDU to its SDS-REPORT PDU and the next node is (non-transparent) SwMI, it may have received other SDS-TRANSFER PDU (from another MS) for which it has sent an SDS-REPORT PDU waiting for an SDS-ACK PDU and the message reference values of the SDS-TRANSFER PDUs happen to be the same. This can happen as each MS allocates independently message references to the SDS-TRANSFER PDUs. In the case of conflict the MS may delay the sending of the SDS-REPORT PDU until it receives an SDS-ACK PDU for the previous one.

#### 29.3.3.4.2 Positive acknowledgement from an MS

If the "Delivery report request" information element in the original SDS-TRANSFER PDU indicates the following acknowledgement type:

- no delivery report requested;

then the destination application shall simply consume the message and shall not send any acknowledgement back to the SwMI.

If the "Delivery report request" information element in the original SDS-TRANSFER PDU indicates:

- message receipt report requested;

and the message is received and successfully decoded, then the destination application shall initiate sending of an acknowledgement to the SwMI using the SDS-REPORT PDU. If the SwMI fails to receive this report, it may retry the delivery. The mechanism determining when to retry the delivery is outside the scope of the present document.

When receiving the acknowledgement, the SwMI should relay this back to the original sending MS. In this case the "Delivery status" information element shall have the following value:

- SDS receipt acknowledged by destination.

If the "Delivery report request" information element in the original SDS-TRANSFER PDU indicates:

- message consumed report requested;

and the message is received and successfully decoded, then the destination application shall initiate sending of an acknowledgement to the SwMI using the SDS-REPORT PDU when the message is consumed. Determining when a message is consumed shall depend on the application which is using the SDS-TL protocol and which is indicated by the protocol identifier (see clause 29.4.3.9). In this case the "Delivery status" information element shall have the following value:

- SDS consumed by destination.

The originator may also request both reports.

The SwMI may control addressing type of the SDS-REPORT PDU by the broadcast information element SDS-TL addressing method, refer to clause 29.3.1.

#### 29.3.3.4.3 Negative acknowledgement from an MS

If a destination receives an individually addressed SDS-TL data transfer service PDU and the MS does not support the specific SDS-TL protocol, or the message cannot be delivered to the peer application, or the destination does not support the application, or the destination cannot receive more messages, then the destination shall issue a negative acknowledgement using the SDS-REPORT PDU. Also the peer application may generate some negative acknowledgements. These error situations are indicated with the "Delivery status" information element set to one of the values outlined in table 29.16 depending on the nature of the error condition (in this table, the MS may return values that indicate a "report source" as "destination").

Note that, if an error occurs when receiving an individually addressed SDS-TL message, the destination shall send a negative acknowledgement regardless of whether or not the originator requested an acknowledgement. If an error occurs when receiving a broadcast or group addressed message, the message shall be silently discarded.

The SwMI may control addressing type by the broadcast information element SDS-TL addressing method, refer to clause 29.3.1.

#### 29.3.3.4.4 Short form acknowledge

A short form acknowledgement SDS-SHORT REPORT PDU is defined and transferred using SDS STATUS PDUs to provide an alternative to using the SDS-REPORT PDU (when using SSI addressing, the short form acknowledgement will fit into a single  $\pi/4$ -QPSK random access burst on the air interface). The SDS-SHORT REPORT PDU may be used to send an acknowledgement from a MS, as described in clauses 29.3.3.4.2 and 29.3.3.4.3 instead of SDS-REPORT PDU.

The SDS-SHORT REPORT PDU may be used when the report is a response to SDS-TRANSFER PDU which contains short form report value "Use of short form report recommended during the validity period of the message" and the validity period has not expired, refer to clause 29.4.3.10. In this case, the destination MS may choose between the SDS-SHORT REPORT PDU and the SDS-REPORT PDU in the cases where the report types available in the short form will suffice. In a transparent transfer mode the SDS-SHORT REPORT PDU may be used even though the validity period is not included into the reported SDS-TRANSFER PDU. The implied validity time is application dependent and outside the scope of the present document.

The short form acknowledgement should be treated by the SwMI and MS equivalent to the corresponding full SDS-REPORT PDU. The SwMI may modify a short report to a standard report for transmission to the original originator of the SDS-TRANSFER which is being reported.

The usage of the SDS-SHORT REPORT PDU is application independent.

The short form report does not contain the Acknowledgement required information element. The implied value of this information element shall be "No further acknowledgements required for this message".

#### 29.3.3.5 Sending an acknowledgement from the source MS

An MS receiving an acknowledgement shall if requested send a delivery report back to the SwMI. Note that the use of the term, "acknowledgement" in this clause refers to an SDS-TL reports and not to the layer 2 acknowledgements which may also be sent as part of the underlying SDS and LLC transport mechanism which are being used by SDS-TL. Also, the generator of the acknowledgement should be the final destination of the report: if the final destination is a host located on the PEI, then the acknowledgement should be generated by the host connected to the PEI.

The SDS-ACK PDU shall, when required, be used to send an acknowledgement back to the sender of the acknowledgement (report). The "Message reference" information element shall be set to be equal to the message reference of the original received message to which the acknowledgement refers. The message reference and source address (of the SDS-ACK PDU) uniquely identifies the message so that the acknowledgement can be matched to the SDS-REPORT PDU in the next node. In the case of transparent SwMI the next node on this protocol point of view is the destination MS.

If the "Delivery report" information element in the SDS-REPORT PDU indicates:

- SDS receipt acknowledged by destination;

and if the "Acknowledgement required" information element indicates that further acknowledgement is needed, then the source application shall initiate sending of an acknowledgement to the SwMI using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- SDS receipt report acknowledgement.

If the "Delivery report" information element in the SDS-REPORT PDU indicates:

- SDS consumed by destination;

and if the "Acknowledgement required" information element indicates that further acknowledgement is needed, then the source application shall initiate sending of an acknowledgement to the SwMI using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- SDS consumed report acknowledgement.

For all negative "Delivery report" information values in the SDS-REPORT PDU and if the "Acknowledgement required" information element indicates that further acknowledgement is needed, then the source application shall initiate sending of an acknowledgement to the SwMI using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- Negative report acknowledgement.

If the requester fails to receive any of these SDS-ACKs, it may retry the delivery of the SDS-REPORT PDU. The mechanism determining when to retry the delivery is outside the scope of the present document.

### 29.3.3.6 Sending an acknowledgement from the SwMI

#### 29.3.3.6.1 General

In most cases, the SwMI is simply a relay for messages and acknowledgements (reports) sent between an originator and destination. An exception to this is the case of an SDS-TRANSFER PDU that cannot be delivered. Note that the use of the term, "acknowledgement" in this sub-clause refers to an SDS-TL report and not to the layer 2 acknowledgements which may also be sent as part of the underlying SDS and LLC transport mechanism which are being used by SDS-TL.

The SDS-REPORT PDU shall be used to send an acknowledgement back to the sender of the message. The "Message reference" information element shall be set to be equal to the message reference of the SDS-TRANSFER PDU to which the acknowledgement refers. The message reference and original source address of the SDS-TRANSFER PDU (i.e. the destination of the SDS-REPORT PDU) uniquely identify a message so that the acknowledgement can be matched to an SDS-TRANSFER PDU in the next node. The message reference may be the only matching element to the SDS-TRANSFER PDU, which is acknowledged, in the originator entity as the use of the original destination address is optional. Refer to clause 29.3.1 on addressing and clause 29.3.2.5 on message reference.

The SDS-ACK PDU shall be used to send an acknowledgement back to the sender of the report, if requested. The "Message reference" information element shall be set to be equal to the message reference of the SDS-REPORT PDU to which the acknowledgement refers. The message reference and source address uniquely identify the message so that the acknowledgement can be matched to the SDS-REPORT PDU.

**NOTE:** In this content the SwMI is the entity which is addressed in the basic SDS PDU such as a store and forward entity, forwarding entity, gateway or a service centre.

#### 29.3.3.6.2 Positive acknowledgement from the SwMI

If the SwMI, a gateway or a storing/forwarding entity (service centre) forward an SDS-TL message to an external network that does not support the SDS-TL services requested by the originator, the SwMI may acknowledge the forwarding of the message. This acknowledgement only acknowledges the fact that the message has been forwarded and is not a guarantee for either delivery or consumption of the message.

In this case the "Delivery report" information element in the SDS-REPORT PDU indicates:

- SDS message forwarded to external network.

The originator will not receive any further acknowledgements for the message.

#### 29.3.3.6.3 Negative acknowledgement from the SwMI

If the SwMI receives an SDS-TL message and the message cannot be delivered to the destination or SwMI detects some error condition (for example, source/destination not authorized for SDS or the network is overloaded) or the message transfer fails for some reason, then the SwMI should issue a negative acknowledgement to the originator using the SDS-REPORT PDU. The "Delivery status" information element is set to one of the values outlined in table 29.16 depending on the nature of the error condition (in this table, the SwMI may return values that indicate a "report source" as "SwMI").

In networks that support storing/forwarding entity, once the validity period has expired, the storing/forwarding entity or SwMI should return an SDS-REPORT with "Delivery status" indicating "validity period expired". The storing/forwarding entity or SwMI should not attempt any further deliveries, and the originating MS should not expect to receive any further reports, for a given message transmission, once "validity period" has expired.

Note that, if an error occurs in the message transfer to the destination, the SwMI should send a negative acknowledgement regardless of whether or not the originator requested an acknowledgement.

#### 29.3.3.6.4 Temporary negative acknowledgement from the SwMI

If the SwMI receives an SDS-TL message and the message cannot be delivered to the destination for a temporary reason (for example, destination is not immediately reachable or the network is overloaded), then the SwMI should issue a temporary negative acknowledgement to the originator using the SDS-REPORT PDU. The "Delivery status" information element is set to one of the values outlined in table 29.16 depending on the nature of the error condition.

The "Delivery status" information element value "Message stored by SwMI" may be used instead of a specific value.

On the reception of these reasons MS should expect that the message will be delivered later and should not resend it before a further failure indication.

#### 29.3.3.7 Sending an acknowledgement from the SwMI to destination MS

An SwMI receiving a report shall if requested send an acknowledgement back to the MS. Note that the use of the term, "acknowledgement" in this clause refers to an SDS-TL ACK PDU and not to the layer 2 acknowledgements which may also be sent as part of the underlying LLC transport mechanism. For the scenario refer to figures 29.7 and 29.8.

The SDS-ACK PDU shall, when required, be used to send an acknowledgement back to the sender of the report. The "Message reference" information element shall be set to be equal to the message reference of the report to which the acknowledgement refers. Only the message reference uniquely identifies the message so that the acknowledgement can be matched to the SDS-REPORT PDU in the MS receiving the SDS-ACK PDU. Refer to clause 29.3.1 on addressing and clause 29.3.2.5 on message reference.

If the "Delivery report" information element in the SDS-REPORT PDU indicates:

- SDS receipt acknowledged by destination

and if the "Acknowledgement required" information element indicates that an acknowledgement is needed, then the SwMI shall initiate sending of an acknowledgement to the MS using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- SDS receipt report acknowledgement.

If the "Delivery report" information element in the SDS-REPORT PDU indicates:

- SDS consumed by destination;

and if the "Acknowledgement required" information element indicates that an acknowledgement is needed, then the SwMI shall initiate sending of an acknowledgement to the MS using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- SDS consumed report acknowledgement.

For all negative "Delivery report" information values in the SDS-REPORT PDU and if the "Acknowledgement required" information element indicates that an acknowledgement is needed, then the SwMI shall initiate sending of an acknowledgement to the SwMI using the SDS-ACK PDU. In this case the "Delivery status" information element shall have the following value:

- Negative report acknowledgement.

If the requester fails to receive any of these SDS-ACKs, it may retry the delivery of the SDS-REPORT PDU. The mechanism determining when to retry the delivery is outside the scope of the present document.

### 29.3.3.8 Using SDS-TL for system broadcast messages

#### 29.3.3.8.1 General

The SwMI may use SDS-TL to generate messages which contain broadcast information for TETRA MS. This service may provide something similar to the GSM cell broadcast service, refer to ETSI TS 144 012 [i.2].

#### 29.3.3.8.2 Sending a broadcast message

The SwMI may send a broadcast message at any time using the SDS-TRANSFER PDU and the SDS bearer service. The SwMI may send such a message to the broadcast address (0xFFFFFFFF hexadecimal) or to a group address and it may repeat the message at intervals dependent on the application using this service. The SwMI should indicate the broadcast address (0xFFFFFFFF hexadecimal) as the source address of the message to allow MSs to react on, or ignore system broadcast messages.

When the SwMI sends a broadcast message, it shall set the protocol identifier to indicate the type of system broadcast information. The system broadcast is thus not limited to text messages, but can be used to transmit other kinds of information, e.g. differential GPS information.

The SwMI shall also set the "Delivery report request" information element to indicate that no delivery report is requested since there shall be no acknowledgement associated with this service.

The "Message reference" information element may be used to indicate different system broadcast messages or it may be changed to indicate that the message has changed.

The "User data" field shall be used in the same way as for point-point and point-to-multipoint transfer described in clause 29.3.3.2.

#### 29.3.3.8.3 Receiving a broadcast message

The MS shall attempt to decode the message according to the protocol identifier and data coding scheme indicated in the header. If the message is a text message and the MS is configured to receive system broadcast messages, then the message may be displayed to the user as it is received.

## 29.4 Coding requirements

### 29.4.1 PDU general structure

The PDUs detailed in clauses 29.4.2.1 to 29.4.2.4 and in clause 29.5 are sub-PDUs of SDS type 4, embedded in the "User defined data-4", refer to clause 14.8.52. The first information element within the "User defined data-4" shall be a protocol identifier. This information element shall identify the application using SDS and the protocol used. The applications using protocol identifiers in the range  $10000000_2$  to  $11111111_2$  shall use the PDUs described in this clause. Applications using protocol identifiers in the range from  $00000000_2$  to  $01111111_2$  shall not use the SDS-TL data transport service protocol (see table 29.21). The PDU descriptions for some of these protocol identifiers are defined in clause 29.5 and the others are outside the scope of the present document.

The general format of the SDS-TL PDU inside the "User defined data-4" information element is defined according to the annex E.

The information elements shall be transmitted in the order specified by the table with the top information element being transmitted first (before interleaving). The content of an information element is represented by a binary value and the most significant bit of that binary value shall be transmitted first (before interleaving).

**Table 29.10: PDU layout**

| Information element            | Length   | Value | Remark                     |
|--------------------------------|----------|-------|----------------------------|
| Protocol identifier            | 8        |       | Refer clause 29.4.3.9      |
| Type 1 information element (1) | variable |       | See definitions in annex E |
| Type 1 information element (2) | variable |       | See definitions in annex E |
| etc.                           | etc.     |       | etc.                       |
| Type 1 information element (n) | variable |       | See definitions in annex E |

The SDS-TL PDUs are intended to be byte-aligned for easier handling by the application. The information elements may be a part of a byte or combination of multiple bytes. There shall be no O-bits or P-bits in the SDS-TL PDUs and the SDS-TL PDU shall fill the whole user data type 4 information element in the D-SDS DATA and U-SDS DATA PDUs.

Information element lengths, values and contents are specified in clause 29.4.2.

The information contained in the following PDU description tables corresponds to the following key:

- Length: length of the information element in bits;
- Type: information element type as defined above;
- C/O/M: conditional/optional/mandatory information in the PDU;
- Remark: comment.

### 29.4.2 PDU Descriptions

#### 29.4.2.0 General

The PDU described in this clause all have mandatory and conditional information elements. However, it should be noted that the entire SDS-TL is not used for some protocol identifiers but only the protocol identifier, refer to clause 29.4.3.9. The mandatory elements are thus only mandatory in the case where the SDS-TL is used.

### 29.4.2.1 SDS-ACK

- Response to: SDS-REPORT PDU
- Response expected: -
- Short description: This PDU shall be used to acknowledge previously received SDS delivery report
- PDU carrier: U/D-SDS DATA PDU User defined data-4 information element.

**Table 29.11: SDS-ACK PDU contents**

| Information element   | Length | Type | C/O/M | Remark   |
|---|--------|------|-------|----------|
| Protocol identifier   | 8      | 1    | M     |          |
| Message type  | 4      | 1    | M     | SDS-ACK  |
| Reserved  | 4      | 1    | M     | See note |
| Delivery status   | 8      | 1    | M     |          |
| Message reference   | 8      | 1    | M     |          |
| NOTE: This field is inserted to ensure that the following information elements are aligned to octet boundaries. In this edition of the present document the field shall be set to "0000 <sub>2</sub> ". |        |      |       |          |

### 29.4.2.2 SDS-REPORT

- Response to: -/SDS-TRANSFER PDU
- Response expected: -/SDS-ACK PDU
- Short description: This PDU shall be used to report on the progress of previously received SDS data.
- PDU carrier: U/D-SDS DATA PDU User defined data-4 information element.

Table 29.12: SDS-REPORT PDU contents

| Information element                         | Length   | Type | C/O/M | Remark            |
|---|----------|------|-------|-------------------|
| Protocol identifier                         | 8        | 1    | M     |                   |
| Message type                                | 4        | 1    | M     | SDS-REPORT        |
| Acknowledgement required                    | 1        | 1    | M     |                   |
| Reserved                                    | 2        | 1    | M     | See note 1        |
| Storage/forward control                     | 1        | 1    | M     |                   |
| Delivery status                             | 8        | 1    | M     |                   |
| Message reference                           | 8        | 1    | M     | See note 2        |
| Validity period                             | 5        | 1    | C     | See note 3        |
| Forward address type                        | 3        | 1    | C     | See note 3        |
| Forward address short number address        | 8        | 1    | C     | See note 4        |
| Forward address SSI                         | 24       | 1    | C     | See note 4        |
| Forward address extension                   | 24       | 1    | C     | See note 4        |
| Number of external subscriber number digits | 8        | 1    | C     | See notes 4 and 5 |
| External subscriber number digit            | 4        | 1    | C     | See note 6        |
| User data                                   | variable | 1    | O     | See note 7        |

NOTE 1: This field is inserted to ensure that the following information elements are aligned to octet boundaries. The field shall be set to "00<sub>2</sub>" by default.

NOTE 2: The value shall be the same as defined by the original source of the PDU.

NOTE 3: This information element shall be present in the PDU only when the "Storage/forward control" information element indicates storage/forward control information available.

NOTE 4: This information element shall be present only when the Forward address type information element is present and indicates an address type that requires presence of the information element.

NOTE 5: The number of external subscriber number digits shall be between 1 and 24 digits.

NOTE 6: This information element shall be present only when the number of external subscriber digits information element is present and it shall contain as many digits as defined in that information element. When the Number of external subscriber number digits information element indicates an odd value the last digit of the external subscriber number shall be followed by an additional digit set to "0" and that additional digit shall not be a part of the external subscriber number.

NOTE 7: This information element is marked to be type 1 and optional on purpose so that there is no O-bit or P-bit before it but the user data length may be zero.

### 29.4.2.3 SDS-SHORT REPORT

- Response to: -/SDS-TRANSFER PDU
- Response expected: -
- Short description: This PDU shall be used to report on the progress of previously received SDS data
- PDU carrier: U/D-STATUS PDU Pre-coded status information element

Table 29.13: SDS-SHORT REPORT PDU contents

| Information element | Length | Value               | Remark   |
|---------------------|--------|---------------------|--|
| SDS-TL PDU          | 6      | 011111 <sub>2</sub> | This status message belongs to the SDS-TL protocol |
| Short report type   | 2      | any                 |  |
| Message reference   | 8      | any                 | The same value as in the corresponding request PDU |

NOTE: The short form acknowledgement does not contain the Acknowledgement required information element. The implied value of this information element defaults to "No further acknowledgements required for this message".

### 29.4.2.4 SDS-TRANSFER

- Response to: -
- Response expected: -/SDS-REPORT
- Short description: This PDU shall be used to send SDS data
- PDU carrier: U/D-SDS DATA PDU User defined data-4 information element.

**Table 29.14: SDS-TRANSFER PDU contents**

| Information element                         | Length   | Type | C/O/M | Remark                 |
|---|----------|------|-------|------------------------|
| Protocol identifier                         | 8        | 1    | M     |                        |
| Message type                                | 4        | 1    | M     | SDS-TRANSFER           |
| Delivery report request                     | 2        | 1    | M     |                        |
| Service selection/Short form report         | 1        | 1    | M     |                        |
| Storage/forward control                     | 1        | 1    | M     |                        |
| Message reference                           | 8        | 1    | M     | See note 1             |
| Validity period                             | 5        | 1    | C     | See note 2             |
| Forward address type                        | 3        | 1    | C     | See note 2             |
| Forward address short number address        | 8        | 1    | C     | See note 3             |
| Forward address SSI                         | 24       | 1    | C     | See note 3             |
| Forward address extension                   | 24       | 1    | C     | See note 3             |
| Number of external subscriber number digits | 8        | 1    | C     | See notes 3 and 4      |
| External subscriber number digit            | 4        | 1    | C     | Repeatable, see note 5 |
| Dummy digit                                 | 4        |      | C     | See note 6             |
| User data                                   | variable | 1    | M     |                        |

NOTE 1: The value shall be defined by the original source of the PDU.  
 NOTE 2: This information element shall be present only, when "Storage/forward control" information element indicates storage/forward control information available.  
 NOTE 3: This information element shall be present only, when Forward address type information element is present and indicates address type that requires presence of the information element.  
 NOTE 4: The length shall be between 1 and 24, refer to clause 14.8.20.  
 NOTE 5: This information element shall be present only, when the number of external subscriber number digits information element is present and it shall be present as many times as defined by the number of external subscriber number digits information element.  
 NOTE 6: This information element shall be present only when the Number of external subscriber number digits information element indicates an odd value. When present the Dummy digit shall be set to "0". The Dummy digit shall not be a part of the external subscriber number. For encoding of each digit refer to clause 14.8.20.

## 29.4.3 Information elements coding

### 29.4.3.1 Acknowledgement required

The Acknowledgement required information element shall indicate as defined in table 29.15 if an SDS-REPORT PDU needs further acknowledgement by an SDS-ACK PDU. This may be requested by either the originator or by the SwMI or the storing/forwarding entity (service centre) if needed.

**Table 29.15: Acknowledgement required information element contents**

| Information element      | Length | Value          | Remark  |
|--------------------------|--------|----------------|---|
| Acknowledgement required | 1      | 0 <sub>2</sub> | No further acknowledgements required for this message |
|                          |        | 1 <sub>2</sub> | Acknowledgement required for this message             |

### 29.4.3.2 Delivery status

The Delivery status information element in SDS-REPORT and SDS-ACK PDUs shall indicate as defined in table 29.16 the status of a previously sent SDS-TRANSFER PDU for which a delivery report has been requested. This information element is also used to communicate error information to an MS when SDS data transfer fails. The "Report source" column in table 29.16 shall indicate whether the status value can be used in a status report sourced by the SwMI or the destination for the message transfer or both. Note that a status report generated by the destination may be relayed back to the originator by the SwMI but this report is still classified as being sourced by the destination. The Service Centre remark indicates how the Service Centre (storing/forwarding entity) or any entity outside the SwMI should interpret the delivery status. A temporary error indicates that the condition is only expected to exist for a limited amount of time. A Service Centre should normally not relay these errors message, but instead send a message indicating that the message have been stored, if such a message have not already been sent. In this way the originator will know that the message have been received by the Service Centre. The Service Centre should therefore re-send the message later. A permanent error is not expected to change, so the Service Centre should not re-send the message later. A Service Centre may though return a delivery status with a Service Centre remark indicating temporary or permanent error when the validity period has expired.

**Table 29.16: Delivery status information element contents**

| Information element   | Length   | Value  | Remark   | Report source | Service Centre remark   |
|-----------------------|--|--|--|---------------|---|
| Delivery status       | 8  | 000XXXXX <sub>2</sub>                          | <b>SDS data transfer success</b>   | -             | SDS data transfer success   |
|                       |  | 00000000 <sub>2</sub>                          | SDS receipt acknowledged by destination  | Destination   | Success   |
|                       |  | 00000001 <sub>2</sub>                          | SDS receipt report acknowledgement   | SwMI/Source   | Success   |
|                       |  | 00000010 <sub>2</sub>                          | SDS consumed by destination  | Destination   | Success   |
|                       |  | 00000011 <sub>2</sub>                          | SDS consumed report acknowledgement  | SwMI/Source   | Success   |
|                       |  | 00000100 <sub>2</sub>                          | SDS message forwarded to external network                                      | SwMI          | Success   |
|                       |  | 00000101 <sub>2</sub>                          | SDS sent to group, acknowledgements prevented                                  | SwMI          | Success   |
|                       |  | 00000110 <sub>2</sub>                          | Concatenation-part receipt acknowledged by destination                         | Destination   | Success   |
|                       |  | 00000111 <sub>2</sub> to 00011111 <sub>2</sub> | Reserved   | -             | Success   |
|                       |  | 001XXXXX <sub>2</sub>                          | <b>Temporary error, SwMI still trying to transfer SDS data</b>                 | -             | SC still trying to transfer SDS data  |
|                       |  | 00100000 <sub>2</sub>                          | Congestion, message stored by SwMI   | SwMI          | -   |
|                       |  | 00100001 <sub>2</sub>                          | message stored by SwMI   | SwMI          | -   |
|                       |  | 00100010 <sub>2</sub>                          | Destination not reachable, message stored by SwMI                              | SwMI          | -   |
|                       |  | 00100011 <sub>2</sub> to 00111111 <sub>2</sub> | Reserved   | -             | See note 2  |
|                       |  | 010XXXXX <sub>2</sub>                          | <b>SDS data transfer failed, SwMI is not making any more transfer attempts</b> | -             | SDS data transfer failed, Service Centre will not make any more transfer attempts |
|                       |  | 01000000 <sub>2</sub>                          | Network overload   | SwMI          | Temporary   |
|                       |  | 01000001 <sub>2</sub>                          | Service permanently not available on BS  | SwMI          | Permanent   |
|                       |  | 01000010 <sub>2</sub>                          | Service temporary not available on BS  | SwMI          | Temporary   |

|                     |        | 101XXXXX <sub>2</sub><br>to<br>111XXXXX <sub>2</sub> | Reserved for future use  | -                      | See note 2            |

NOTE 1: These values may be co-ordinated outside the scope of the present document in order to prevent clashes.

NOTE 2: These values may change in future versions of the present document.

NOTE 3: Message transfer has failed on the reporting entity point of view.

### 29.4.3.3 Delivery report request

The Delivery report request information element shall indicate as defined in table 29.17 the type of delivery report which is being requested by the sender of SDS-TRANSFER PDU. This delivery report may be generated either by the SwMI or the destination for the message depending on the type of report. Note that this information element is a bitmap to allow multiple combinations of the types of report (end-to-end acknowledgement) to be requested.

**Table 29.17: Delivery report request information element contents**

| Information element  | Length | Value           | Remark   |
|--|--------|-----------------|--|
| Delivery report request  | 2      | 00 <sub>2</sub> | No delivery report requested                   |
|  |        | 01 <sub>2</sub> | Message received report requested (see note 1) |
|  |        | 10 <sub>2</sub> | Message consumed report requested (see note 2) |
|  |        | 11 <sub>2</sub> | Message received and consumed report requested |
| NOTE 1: This delivery report type shall indicate that the sender of the message is requesting a report when the message has been received by the destination.  |        |                 |  |
| NOTE 2: This delivery report type shall indicate that the sender of the message is requesting a report when the message has been consumed by the destination. A message is consumed when the application processes the message. For example, in the case of text messaging, a message is consumed when the user reads the message. |        |                 |  |

### 29.4.3.4 Dummy digit

The Dummy digit information element shall fill unused 4 bits in the case of an odd number of digits in the address information element in order to keep octet boundaries. The only applicable value of the digit shall be "0000<sub>2</sub>" and all other values shall be reserved.

### 29.4.3.5 Forward address type

The Forward address type information element shall indicate as defined in table 29.18 the type of address in the "Forward address" information element.

NOTE: The usage of a short number address as a forward address requires that the SwMI (storing/forwarding entity or service centre) to which MS addresses the U-SDS-DATA PDU supports supplementary service SS-SNA for the sending MS, refer to ETSI EN 300 392-10-7 [i.4], ETSI EN 300 392-11-7 [i.5] and ETSI EN 300 392-12-7 [13].

**Table 29.18: Forward address type information element contents**

| Information element  | Length | Value            | Remark                                   |
|--|--------|------------------|--|
| Forward address type   | 3      | 000 <sub>2</sub> | Short Number Address (SNA) (see note 1)  |
|  |        | 001 <sub>2</sub> | Short Subscriber Identity (SSI)          |
|  |        | 010 <sub>2</sub> | TETRA Subscriber Identity (TSI)          |
|  |        | 011 <sub>2</sub> | External subscriber number               |
|  |        | 100 <sub>2</sub> | Reserved                                 |
|  |        | 101 <sub>2</sub> | Reserved                                 |
|  |        | 110 <sub>2</sub> | Reserved                                 |
|  |        | 111 <sub>2</sub> | No forward address present (see note 2). |
| NOTE 1: The short number addressing is applicable only in messages from an MS to SwMI direction. |        |                  |  |
| NOTE 2: Refer to clause 29.3.1 for usage of this value.  |        |                  |  |

### 29.4.3.6 Forward address

The Forward address information element, if present, is one of SNA, SSI or TSI as defined in ETSI EN 300 392-1 [6], clause 7 or an External subscriber number. The forward address may be used to convey the true source/destination address to a network service point or service user.

### 29.4.3.7 Message reference

The message reference information element shall give as defined in table 29.19 an integer representation of a reference number of an SDS-TRANSFER PDU submitted to the SwMI by an MS.

**Table 29.19: Message reference information elements contents**

| Information element | Length | Value  | Remark   |
|---------------------|--------|--|----------|
| Message reference   | 8      | 00000000 <sub>2</sub> to 11111111 <sub>2</sub> | 0 to 255 |

### 29.4.3.8 Message type

The Message type information element shall identify as defined in table 29.20 the SDS-TL message type being conveyed by the SDS user defined data service.

**Table 29.20: Message type information element contents**

| Information element   | Length | Value                                     | Remark   |
|---|--------|---|--|
| Message type  | 4      | 0XXX <sub>2</sub>                         | Message transfer protocol is defined by SDS-TL |
|   |        | 0000 <sub>2</sub>                         | SDS-TRANSFER                                   |
|   |        | 0001 <sub>2</sub>                         | SDS-REPORT                                     |
|   |        | 0010 <sub>2</sub>                         | SDS-ACK  |
|   |        | 0011 <sub>2</sub> to<br>0111 <sub>2</sub> | Reserved for additional message types          |
|   |        | 1XXX <sub>2</sub>                         | Defined by application (see note)              |
| NOTE: In this case, the format of the SDS user data shall be defined by the application and not necessarily conforming to this transport protocol standard. |        |   |  |

## 29.4.3.9 Protocol identifier

The Protocol identifier information element shall refer to the user application utilizing the SDS-TL protocol as defined in table 29.21.

Table 29.21: Protocol identifier information element contents

| Information element                            | Length   | Value  | Remark   | Clause  |
|--|--|--|--|---------|
| Protocol identifier                            | 8  | 00000000 <sub>2</sub>                          | Reserved, (see notes 1 and 2)  | -       |
|  |  | 00000001 <sub>2</sub>                          | OTAK (Over The Air re-Keying for end to end encryption), refer to ETSI EN 300 392-7 [8] V2.1.1 clause 7.6 or ETSI ES 202 109 [3] clause 4.6, (see notes 2 and 3) | 29.5.1  |
|  |  | 00000010 <sub>2</sub>                          | Simple Text Messaging, (see note 2)  | 29.5.2  |
|  |  | 00000011 <sub>2</sub>                          | Simple location system, (see note 2)   | 29.5.5  |
|  |  | 00000100 <sub>2</sub>                          | Wireless Datagram Protocol WAP, (see note 2)   | 29.5.8  |
|  |  | 00000101 <sub>2</sub>                          | Wireless Control Message Protocol WCMP, (see note 2)   | 29.5.8  |
|  |  | 00000110 <sub>2</sub>                          | M-DMO (Managed DMO), refer to ETSI EN 300 396-10 [26], (see note 2)  | 29.5.1  |
|  |  | 00000111 <sub>2</sub>                          | PIN authentication, (see note 2)   | 29.5.1  |
|  |  | 00001000 <sub>2</sub>                          | End-to-end encrypted message, (see notes 2 and 6)  | -       |
|  |  | 00001001 <sub>2</sub>                          | Simple immediate text messaging, (see note 2)  | 29.5.2  |
|  |  | 00001010 <sub>2</sub>                          | Location information protocol, (see note 2)  | 29.5.12 |
|  |  | 00001011 <sub>2</sub>                          | Net Assist Protocol 2 (NAP2), (see notes 2 and 9)  | 29.5.13 |
|  |  | 00001100 <sub>2</sub>                          | Concatenated SDS message, (see note 2)   | 29.5.14 |
|  |  | 00001101 <sub>2</sub>                          | DOTAM, refer to ETSI TS 100 392-18-3 [48], (see note 2)  | 29.5.1  |
|  |  | 00001110 <sub>2</sub>                          | Simple AGNSS service, (see notes 2 and 9)  | 29.5.15 |
|  |  | 00001111 <sub>2</sub> to 00111111 <sub>2</sub> | Reserved for future standard definition, (see note 2)  | 29.5.1  |
|  |  | 01000000 <sub>2</sub> to 01111110 <sub>2</sub> | Available for user application definition, (see notes 2 and 4)   | 29.5.1  |
|  |  | 01111111 <sub>2</sub>                          | Reserved for extension, (see notes 2 and 7)  | -       |
|  |  | 10000000 <sub>2</sub> to 10000001 <sub>2</sub> | Reserved, (see note 5)   | -       |
|  |  | 10000010 <sub>2</sub>                          | Text Messaging, (see note 5)   | 29.5.3  |
|  |  | 10000011 <sub>2</sub>                          | Location system, (see note 5)  | 29.5.6  |
|  |  | 10000100 <sub>2</sub>                          | Wireless Datagram Protocol WAP, (see note 5)   | 29.5.8  |
|  |  | 10000101 <sub>2</sub>                          | Wireless Control Message Protocol WCMP, (see note 5)   | 29.5.8  |
|  |  | 10000110 <sub>2</sub>                          | M-DMO (Managed DMO), refer to ETSI EN 300 396-10 [26], (see note 5)  | 29.5.1  |
|  |  | 10000111 <sub>2</sub>                          | Reserved for future standard definition, (see note 5)  | -       |
|  |  | 10001000 <sub>2</sub>                          | End-to-end encrypted message, (see notes 5 and 6)  | -       |
|  |  | 10001001 <sub>2</sub>                          | Immediate text messaging, (see note 5)   | 29.5.3  |
|  |  | 10001010 <sub>2</sub>                          | Message with User Data Header  | 29.5.9  |
|  |  | 10001011 <sub>2</sub>                          | Reserved for future standard definition (see note 5)   | -       |
|  |  | 10001100 <sub>2</sub>                          | Concatenated SDS message, (see notes 5 and 8)  | 29.5.14 |
|  |  | 10001101 <sub>2</sub>                          | AGNSS service (see note 9)   | 29.5.16 |
|  |  | 10001110 <sub>2</sub> to 10111111 <sub>2</sub> | Reserved for future standard definition, (see note 5)  | -       |
| 11000000 <sub>2</sub> to 11111110 <sub>2</sub> | Available for user application definition, (see notes 4 and 5) | -  |  |         |
| 11111111 <sub>2</sub>                          | Reserved for extension, (see notes 5 and 7)                    | -  |  |         |

| Information element | Length | Value | Remark   | Clause |
|---------------------|--------|-------|--|--------|
| NOTE 1:             |        |       | This protocol identifier value should not be used as it is not allocated for a pre-defined application.  |        |
| NOTE 2:             |        |       | The SDS-TL data transfer service shall not be used for these protocol identifiers, refer to clause 29.4.1.   |        |
| NOTE 3:             |        |       | In the ETSI EN 300 392-7 [8] clause 7.6 or ETSI ES 202 109 [3] clause 4.6 the protocol identifier is identified as "SDS type 4 header".  |        |
| NOTE 4:             |        |       | The assignment of these protocol identifiers will be co-ordinated in order to prevent clashes, refer to annex J.   |        |
| NOTE 5:             |        |       | The SDS-TL data transfer service shall be used for these protocol identifiers.   |        |
| NOTE 6:             |        |       | Refer to TETRA MoU SFPG recommendation 07 for information.   |        |
| NOTE 7:             |        |       | This value shall indicate that the next 8 bits long value is the protocol identifier and the 16 bits replaces the eight bits of the protocol identifier in the PDUs using this extension method. |        |
| NOTE 8:             |        |       | The specific usage for concatenation layer is defined in clause 29.5.14.   |        |
| NOTE 9:             |        |       | An AGNSS PID is added that is different from NAP2 PID, as AGNSS is a separate broadcast service, while NAP2 is a more general service for requesting ondemand some specific AGNSS data.          |        |

### 29.4.3.10 Service selection/short form report

The Service selection information element shall indicate as defined in table 29.22 on the uplink if the message is allowed to be sent to a group address and on the downlink whether a short form report is allowed for this message. If the value of this information element is set to "individual service" when the destination address is a group address, the SwMI may reject the message.

**Table 29.22: Service selection/ short form report information element contents**

| Information element                 | Length | Value          | Remark   |
|-------------------------------------|--------|----------------|--|
| Service selection/short form report | 1      | 0 <sub>2</sub> | Uplink: Individual service<br>Downlink: Use of short form report recommended during the validity period of the message |
|                                     |        | 1 <sub>2</sub> | Uplink: Group or individual service<br>Downlink: Only standard report allowed  |

### 29.4.3.11 Short report type

The Short report type information element shall indicate the reason for report as defined in table 29.23.

**Table 29.23: Short report type information element contents**

| Information element | Length | Value           | Remark                          |
|---------------------|--------|-----------------|---------------------------------|
| Short report type   | 2      | 00 <sub>2</sub> | Protocol/encoding not supported |
|                     |        | 01 <sub>2</sub> | Destination memory full         |
|                     |        | 10 <sub>2</sub> | Message received                |
|                     |        | 11 <sub>2</sub> | Message consumed                |

### 29.4.3.12 Storage/forward control

The Storage/forward control information element shall indicate as defined in table 29.24 if the SwMI is allowed to store the message longer than needed for ordinary processing and whether a storing/forwarding entity is specified. If storage/forward control information is available, the "Validity period" and "Forward address" information elements are present.

**Table 29.24: Storage/forward control information element contents**

| Information element     | Length | Value          | Remark  |
|-------------------------|--------|----------------|---|
| Storage/forward control | 1      | 0 <sub>2</sub> | Storage/forward control information not available |
|                         |        | 1 <sub>2</sub> | Storage/forward control information is available  |

### 29.4.3.13 User data

The User data information element contains the application data which is coded according to the protocol identified by the Protocol identifier and, if present, the data coding scheme information elements.

### 29.4.3.14 Validity period

The Validity period information element shall indicate the length of time after receiving an SDS-TRANSFER PDU that the SwMI should attempt to deliver the message. If this time expires, the SwMI shall stop delivery attempts and may report message failure to the sending MS. The values shall be as defined in table 29.25. The applied validity period in the SwMI should not be less than the requested validity period and should not be longer than the requested validity period plus one hour or a network dependent value.

**Table 29.25: Validity period information element contents**

| Information element  | Length | Value    | Remark                                 |
|--|--------|----------|--|
| Validity period (VP)   | 5      | 0        | No validity period, (see note 1)       |
|  |        | 1 to 6   | VP × 10 seconds, (see note 2)          |
|  |        | 7 to 10  | (VP - 5) × 1 minute, (see note 3)      |
|  |        | 11 to 16 | (VP - 10) × 10 minutes, (see note 4)   |
|  |        | 17 to 21 | (VP - 15) × 1 hour, (see note 5)       |
|  |        | 22 to 24 | (VP - 20) × 6 hours, (see note 6)      |
|  |        | 25 to 30 | (VP - 24) × 2 days, (see note 7)       |
|  |        | 31       | Infinite validity period, (see note 8) |
| NOTE 1: In this case, the SwMI should attempt to deliver the message. If unsuccessful, the message is dropped.         |        |          |  |
| NOTE 2: 10 second intervals up to 60 seconds.  |        |          |  |
| NOTE 3: 1 minute intervals up to 5 minutes.  |        |          |  |
| NOTE 4: 10 minute intervals up to 1 hour.  |        |          |  |
| NOTE 5: 1 hour intervals up to 6 hours.  |        |          |  |
| NOTE 6: 6 hour intervals up to 24 hours.   |        |          |  |
| NOTE 7: 2 day intervals up to 12 days.   |        |          |  |
| NOTE 8: In this case, the SwMI should attempt to deliver the message until expiry of a network dependant maximum time. |        |          |  |

## 29.5 Protocol specific definitions

### 29.5.0 General

This clause defines information elements specific to the some of the standardized protocol identifiers.

### 29.5.1 Standardized protocols using SDS Type 4 without SDS-TL

#### 29.5.1.0 General

For TETRA some services use SDS type 4 without SDS-TL data transport service as information carrier. Some of these protocols will be defined in other TETRA standards such as OTAR for the end-to-end encryption key management mechanism.

#### 29.5.1.1 Protocol sequences

These protocols shall not use the SDS-TL acknowledgement and storing/forwarding entity services. For protocol sequences refer to references in table 29.21.

### 29.5.1.2 PDU Description tables

The minimum standardized information element of these "simple" protocols defined in clause 29 is the protocol identifier. For all other aspects refer to the specific protocol as indicated in the table 29.21. The standardized simple protocol PDUs shall be constructed as defined for the User Defined Data-4 information element in clause 14.8.52. Thus the minimum information elements shall be as defined in table 29.26 unless more elements are defined in the specific protocol description.

**Table 29.26: Standardized "simple" protocol PDU contents**

| Information element  | Length   | Type | C/O/M | Remark               |
|----------------------|----------|------|-------|----------------------|
| Protocol identifier  | 8        | 1    | M     | Refer to table 29.21 |
| Protocol information | variable | 1    | M     |                      |

## 29.5.2 Simple text messaging

### 29.5.2.0 General

The Simple text message protocol is intended to be a very basic text messaging application defined to a degree where interoperability can be expected. Mechanisms how Simple text messages are presented to the user is outside the scope of the present document.

When a mobile terminated text message is indicated to be a Simple immediate text message and the MS has the capability of displaying short messages, the MS shall display the message immediately. Otherwise the protocol for Simple immediate text messaging is the same as in case of normal simple text messaging. If the MS is incapable of displaying Simple immediate text messages, they can be handled as a normal simple text message.

### 29.5.2.1 Protocol sequences

Simple text message protocol does not use any end-to-end acknowledgement or storing/forwarding entity mechanisms. The only delivery acknowledgement mechanisms offered is the layer 2 acknowledge independently on each hop.

### 29.5.2.2 PDU description tables

Simple text messaging does not use the SDS-TL data transfer service PDUs, but defines a protocol specific field to specify the data format, refer to 29.5.4.1. The basic SDS type-4 information element shall contain elements as defined in clause 29.5.2.3, refer to clause 14.8.52.

### 29.5.2.3 Simple text messaging

- Response to: -
- Response expected: -
- Short description: This PDU shall be used to send simple text messaging SDS data
- PDU carrier:

**Table 29.27: Simple text messaging PDU contents**

| Information element   | Length   | Type | C/O/M | Remark                    |
|---|----------|------|-------|---------------------------|
| Protocol identifier   | 8        | 1    | M     | Refer to table 29.21      |
| Reserved  | 1        | 1    | M     | See note 1                |
| Text coding scheme  | 7        | 1    | M     | As defined in table 29.29 |
| Text  | variable | 1    | M     | See note 2                |
| NOTE 1: This information element is added in order to keep octet boundaries and to align encoding with the text messaging, refer to clause 29.5.3.3 where the timestamp used information element is in the position. The value of this information element shall be set to "0". |          |      |       |                           |
| NOTE 2: The text shall be encoded as defined in the text coding scheme information element.   |          |      |       |                           |

## 29.5.3 Text messaging using SDS-TL

### 29.5.3.0 General

The text message protocol offers either a store and forward mechanism in the SwMI or acknowledgements (reports) from destination or both as selected by the originating MS. Mechanisms how normal text messages are presented to the user is outside the scope of the present document.

When a mobile terminated text message is indicated to be an Immediate text message and the MS has the capability of displaying short messages, the MS shall display the message immediately. Otherwise the protocol functionality for Immediate text messaging is the same as in case of normal text messaging. If the MS is incapable of displaying Immediate text messages, they can be handled as a normal text message. For Immediate text messages a message consumed report shall be sent only after the user has performed an action that can be taken as an indication that the Immediate text message is read. The related man machine actions are outside the scope of the present document.

### 29.5.3.1 Protocol sequences

The protocol sequences of text messaging shall be the unmodified protocol sequences defined in clause 29.3.3.

### 29.5.3.2 PDU description tables

The text messaging protocol uses the full SDS-TL data transport service protocol. The text messaging protocol defines additional information elements which are transported in the SDS-TRANSFER PDU.

### 29.5.3.3 Text message transfer SDU

The text message transfer is done by use of an SDS-TRANSFER PDU with additional information elements embedded in the user data portion of the SDS-TRANSFER PDU. The SDU part as defined in table 29.28 shall be the user data in the SDS-TRANSFER PDU, refer to table 29.14.

**Table 29.28: Text message transfer SDU contents**

| Information element   | Length   | Type | C/O/M | Remark                                 |
|---|----------|------|-------|--|
| Time stamp used   | 1        | 1    | M     | As defined in table 29.41 (see note 1) |
| Text coding scheme  | 7        | 1    | M     | As defined in table 29.29 (see note 1) |
| Time stamp  | 24       | 1    | C     | As defined in table 29.40 (see note 2) |
| Text  | variable | 1    | M     | See note 3                             |
| NOTE 1: These two elements can be processed together in order to keep byte alignment.                                 |          |      |       |  |
| NOTE 2: This information element shall be present only, when the Time stamp used indicates the presence of timestamp. |          |      |       |  |
| NOTE 3: The text shall be encoded as defined in the text coding scheme information element.                           |          |      |       |  |

### 29.5.3.4 Text message short form acknowledgement

The text messaging may use the SDS-SHORT REPORT PDU as defined in clause 29.4.4.4.

The destination MS can choose between the SDS-SHORT REPORT PDU and the SDS-REPORT PDU in the cases where the report types available in the short form will suffice, refer to clause 29.3.3.4.4.

## 29.5.4 Text messaging information elements

### 29.5.4.1 Text coding scheme

The text coding of the user data in an SDS message shall be specified by the Text coding scheme information element. The text coding schemes defined in the present document are:

- 7-bit alphabet;
- 8-bit alphabets;

- UCS-2 with the UTF-16BE extension.

The 7-bit alphabet is identical to the GSM default alphabet, refer to ETSI TS 100 900 [1] and this is the 7-bit alphabet which shall be used by the TETRA SDS-TL service defined in the present document.

The 8-bit alphabets defined in the present document are a broad range of available alphabets produced by ISO/IEC 8859 [40], PC code pages and IETF RFCs, supporting character sets for multiple languages.

The UCS2 alphabet is coded according to the 16-bit UCS2 standard produced by ISO, refer to ISO/IEC 10646 [41] and the Unicode Standard in the annex L Bibliography. This alphabet supports an enhanced selection of characters to support non-Latin languages and is set to become the basic coding form for all 16 bit and 32-bit computer systems during 1997. This alphabet is also supported by GSM.

The text coding scheme shall be as defined in table 29.29.

NOTE: The timestamp used, refer table 29.41, and the text coding scheme information elements could be processed together in order to keep byte alignment in the protocol.

Table 29.29: Text coding scheme information element contents

| Information element   | Length  | Value                | Remark  |
|---|---|----------------------|---|
| Text coding scheme  | 7   | 000000 <sub>2</sub>  | 7-bit alphabet, see clause 29.5.4.3, see note 1                   |
|   |   | 0000001 <sub>2</sub> | ISO/IEC 8859-1 Latin 1 (8-bit) alphabet [40], see note 1          |
|   |   | 0000010 <sub>2</sub> | ISO/IEC 8859-2 Latin 2 (8-bit) alphabet [40]                      |
|   |   | 0000011 <sub>2</sub> | ISO/IEC 8859-3 Latin 3 (8-bit) alphabet [40]                      |
|   |   | 0000100 <sub>2</sub> | ISO/IEC 8859-4 Latin 4 (8-bit) alphabet [40]                      |
|   |   | 0000101 <sub>2</sub> | ISO/IEC 8859-5 Latin/Cyrillic (8-bit) alphabet [40]               |
|   |   | 0000110 <sub>2</sub> | ISO/IEC 8859-6 Latin/Arabic (8-bit) alphabet [40]                 |
|   |   | 0000111 <sub>2</sub> | ISO/IEC 8859-7 Latin/Greek (8-bit) alphabet [40]                  |
|   |   | 0001000 <sub>2</sub> | ISO/IEC 8859-8 Latin/Hebrew (8-bit) alphabet [40]                 |
|   |   | 0001001 <sub>2</sub> | ISO/IEC 8859-9 Latin 5 (8-bit) alphabet [40]                      |
|   |   | 0001010 <sub>2</sub> | ISO/IEC 8859-10 Latin 6 (8-bit) alphabet [40]                     |
|   |   | 0001011 <sub>2</sub> | ISO/IEC 8859-13 Latin 7 (8-bit) alphabet [40]                     |
|   |   | 0001100 <sub>2</sub> | ISO/IEC 8859-14 Latin 8 (8-bit) alphabet [40]                     |
|   |   | 0001101 <sub>2</sub> | ISO/IEC 8859-15 Latin 0 (8-bit) alphabet [40]                     |
|   |   | 0001110 <sub>2</sub> | PC code page 437 (United States)                                  |
|   |   | 0001111 <sub>2</sub> | PC code page 737 (Greek II)                                       |
|   |   | 0010000 <sub>2</sub> | PC code page 850 (Latin I)  |
|   |   | 0010001 <sub>2</sub> | PC code page 852 (Eastern Europe/Latin II)                        |
|   |   | 0010010 <sub>2</sub> | PC code page 855 (Cyrillic I)                                     |
|   |   | 0010011 <sub>2</sub> | PC code page 857 (Turkish)  |
|   |   | 0010100 <sub>2</sub> | PC code page 860 (Portuguese)                                     |
|   |   | 0010101 <sub>2</sub> | PC code page 861 (Icelandic)                                      |
|   |   | 0010110 <sub>2</sub> | PC code page 863 (Canadian/French)                                |
|   |   | 0010111 <sub>2</sub> | PC code page 865 (Nordic)   |
|   |   | 0011000 <sub>2</sub> | PC code page 866 (Russian/Cyrillic II)                            |
|   |   | 0011001 <sub>2</sub> | PC code page 869 (Greek)  |
|   |   | 0011010 <sub>2</sub> | ISO/IEC 10646-1 [41] UCS-2/UTF-16BE (16-bit) alphabet, see note 1 |
|   |   | 0011011 <sub>2</sub> | IETF RFC 1456 [47] VISCII (Vietnamese)                            |
|   |   | 0011100 <sub>2</sub> | Reserved  |
|   |   | etc.                 | etc.  |
| 0011111 <sub>2</sub>  | Reserved  |                      |   |
| 0100000 <sub>2</sub>  | Available for user application definition, see note 2 |                      |   |
| etc.  | etc.  |                      |   |
| 1111110 <sub>2</sub>  | Available for user application definition, see note 2 |                      |   |
| 1111111 <sub>2</sub>  | Reserved for text coding scheme extension, see note 3 |                      |   |
| NOTE 1: These are the recommended character sets.   |   |                      |   |
| NOTE 2: Identities of these text coding schemes should be allocated by a central body in order to support interoperability. |   |                      |   |
| NOTE 3: Extension definition is outside the scope of the present document.  |   |                      |   |

The "7-bit alphabet" shall indicate that the user data is coded using the 7-bit alphabet given in clause 29.5.4.3. When this alphabet is used, the characters of the message are packed into octets so that 285 characters can be transported in 250 bytes of user data. The support of the 7-bit alphabet is optional for MS equipment supporting the SDS-TL service.

Several 8-bit alphabets are listed as well, however, the list is very long and it is unlikely that an MS will support all 8-bit coding schemes. In case the MS receives a message in an unknown alphabet, the MS may reject the message using Delivery status value "Data coding scheme not supported" or map the unsupported alphabet to an alphabet supported by the MS.

The UCS-2 alphabet indicates that the user data is coded according to the UCS-2 coding scheme, employing the UTF-16 extension of ISO/IEC 10646 [41] using the "BE" (Big Endian) form. While using SDS-TL the Byte Order Mark (BOM) shall not be used as "BE" format shall be the only format defined.

UTF-16BE uses two consecutive values to represent a character beyond the Basic Multilingual Plane (i.e. Plane 00). As the "BE" form is stated, the "value" for the high-half zone (D800-DCFF) shall precede the "value" for the low-half zone (DB00-DFFF), refer to ISO/IEC 10646 [41].

### 29.5.4.2 Character packing

A 7-bit character number  $\alpha$  is represented as shown in table 29.30.

**Table 29.30: 7-bit character presentation**

| b7         | b6         | b5         | b4         | b3         | b2         | b1         |
|------------|------------|------------|------------|------------|------------|------------|
| $\alpha a$ | $\alpha b$ | $\alpha c$ | $\alpha d$ | $\alpha e$ | $\alpha f$ | $\alpha g$ |

A 7-bit character number  $\alpha$  has bit "a" as the most significant bit "b7" and bit "g" as the least significant bit "b1".

For the 7-bit alphabet, characters shall first be packed into octets according to ETSI TS 100 900 [1] and then inserted octet-by-octet into the user data information element. The unused part of the last octet shall be padded by zeros, if needed.

Tables 29.31 to 29.33 present examples of the 7-bit character packing into octets, refer to ETSI TS 100 900 [1] clause 6.1.2.1.1 for further examples.

**Table 29.31: One 7-bit character in one octet**

|         | Bits number |    |    |    |    |    |    |    |
|---------|-------------|----|----|----|----|----|----|----|
|         | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Octet 1 | 0           | 1a | 1b | 1c | 1d | 1e | 1f | 1g |

**Table 29.32: Two 7-bit characters in two octets**

|         | Bits number |    |    |    |    |    |    |    |
|---------|-------------|----|----|----|----|----|----|----|
|         | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Octet 1 | 2g          | 1a | 1b | 1c | 1d | 1e | 1f | 1g |
| Octet 2 | 0           | 0  | 2a | 2b | 2c | 2d | 2e | 2f |

**Table 29.33: Seven 7-bit characters in seven octets**

|         | Bits number |    |    |    |    |    |    |    |
|---------|-------------|----|----|----|----|----|----|----|
|         | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Octet 1 | 2g          | 1a | 1b | 1c | 1d | 1e | 1f | 1g |
| Octet 2 | 3f          | 3g | 2a | 2b | 2c | 2d | 2e | 2f |
| Octet 3 | 4e          | 4f | 4g | 3a | 3b | 3c | 3d | 3e |
| Octet 4 | 5d          | 5e | 5f | 5g | 4a | 4b | 4c | 4d |
| Octet 5 | 6c          | 6d | 6e | 6f | 6g | 5a | 5b | 5c |
| Octet 6 | 7b          | 7c | 7d | 7e | 7f | 7g | 6a | 6b |
| Octet 7 | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 7a |

NOTE 1: If the last octet contains 7 padding zeros those can be misinterpreted as an "@" character, refer to table 29.33. In that case use of Carriage Return character instead of zero padding will prevent presentation of the "@" character.

The octets containing 7-bit characters shall be set into the user data information element as shown in table 29.34 for the case of four 7-bit characters.

**Table 29.34: Character packing for 7-bit alphabet**

|               | Octet 1 |      |      |      |      |      |      |      | Octet 2 |      |      |      |      |      |      |      |
|---------------|---------|------|------|------|------|------|------|------|---------|------|------|------|------|------|------|------|
| Bit position  | n       | n-1  | n-2  | n-3  | n-4  | n-5  | n-6  | n-7  | n-8     | n-9  | n-10 | n-11 | n-12 | n-13 | n-14 | n-15 |
| Character bit | 2g      | 1a   | 1b   | 1c   | 1d   | 1e   | 1f   | 1g   | 3f      | 3g   | 2a   | 2b   | 2c   | 2d   | 2e   | 2f   |
|               | Octet 3 |      |      |      |      |      |      |      | Octet 4 |      |      |      |      |      |      |      |
| Bit position  | n-16    | n-17 | n-18 | n-19 | n-20 | n-21 | n-22 | n-23 | n-24    | n-25 | n-26 | n-27 | n-28 | n-29 | n-30 | n-31 |
| Character bit | 4e      | 4f   | 4g   | 3a   | 3b   | 3c   | 3d   | 3e   | 0       | 0    | 0    | 0    | 4a   | 4b   | 4c   | 4d   |

NOTE 2: In GSM, the LSB of each octet is transmitted first. However, in TETRA, the PDUs are packed such that the MSB of each octet is transmitted first as indicated in tables 29.34, 29.36 and 29.38.

An 8-bit character number  $\alpha$  is represented as shown in table 29.35.

**Table 29.35: 8-bit character presentation**

| b8         | b7         | b6         | b5         | b4         | b3         | b2         | b1         |
|------------|------------|------------|------------|------------|------------|------------|------------|
| $\alpha a$ | $\alpha b$ | $\alpha c$ | $\alpha d$ | $\alpha e$ | $\alpha f$ | $\alpha g$ | $\alpha h$ |

An 8-bit character number  $\alpha$  has bit "a" as the most significant bit "b8" and bit "h" as the least significant bit "b1".

The 8-bit characters shall be set into the user data information element as shown in table 29.36 for the case of four 8-bit characters.

**Table 29.36: Character packing for 8-bit alphabet**

|               | Octet 1 |      |      |      |      |      |      |      | Octet 2 |      |      |      |      |      |      |      |
|---------------|---------|------|------|------|------|------|------|------|---------|------|------|------|------|------|------|------|
| Bit position  | n       | n-1  | n-2  | n-3  | n-4  | n-5  | n-6  | n-7  | n-8     | n-9  | n-10 | n-11 | n-12 | n-13 | n-14 | n-15 |
| Character bit | 1a      | 1b   | 1c   | 1d   | 1e   | 1f   | 1g   | 1h   | 2a      | 2b   | 2c   | 2d   | 2e   | 2f   | 2g   | 2h   |
|               | Octet 3 |      |      |      |      |      |      |      | Octet 4 |      |      |      |      |      |      |      |
| Bit position  | n-16    | n-17 | n-18 | n-19 | n-20 | n-21 | n-22 | n-23 | n-24    | n-25 | n-26 | n-27 | n-28 | n-29 | n-30 | n-31 |
| Character bit | 3a      | 3b   | 3c   | 3d   | 3e   | 3f   | 3g   | 3h   | 4a      | 4b   | 4c   | 4d   | 4e   | 4f   | 4g   | 4h   |

A 16-bit character number  $\alpha$  is represented as shown in table 29.37.

**Table 29.37: 16-bit character presentation**

| b16        | b15        | b14        | b13        | b12        | b11        | b10        | b9         | b8         | b7         | b6         | b5         | b4         | b3         | b2         | b1         |
|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| $\alpha a$ | $\alpha b$ | $\alpha c$ | $\alpha d$ | $\alpha e$ | $\alpha f$ | $\alpha g$ | $\alpha h$ | $\alpha i$ | $\alpha j$ | $\alpha k$ | $\alpha l$ | $\alpha m$ | $\alpha n$ | $\alpha o$ | $\alpha p$ |

A 16-bit character number  $\alpha$  has bit "a" as the most significant bit "b16" and bit "p" as the least significant bit "b1".

The 16-bit characters shall be set into the user data information element as shown in table 29.38 for the case of two 16-bit characters.

**Table 29.38: Character packing for 16-bit alphabet**

|               | Octet 1 |      |      |      |      |      |      |      | Octet 2 |      |      |      |      |      |      |      |
|---------------|---------|------|------|------|------|------|------|------|---------|------|------|------|------|------|------|------|
| Bit position  | n       | n-1  | n-2  | n-3  | n-4  | n-5  | n-6  | n-7  | n-8     | n-9  | n-10 | n-11 | n-12 | n-13 | n-14 | n-15 |
| Character bit | 1a      | 1b   | 1c   | 1d   | 1e   | 1f   | 1g   | 1h   | 1i      | 1j   | 1k   | 1l   | 1m   | 1n   | 1o   | 1p   |
|               | Octet 3 |      |      |      |      |      |      |      | Octet 4 |      |      |      |      |      |      |      |
| Bit position  | n-16    | n-17 | n-18 | n-19 | n-20 | n-21 | n-22 | n-23 | n-24    | n-25 | n-26 | n-27 | n-28 | n-29 | n-30 | n-31 |
| Character bit | 2a      | 2b   | 2c   | 2d   | 2e   | 2f   | 2g   | 2h   | 2i      | 2j   | 2k   | 2l   | 2m   | 2n   | 2o   | 2p   |

### 29.5.4.3 7-bit alphabet table

The 7-bit alphabet shall be exactly the same as that specified by the GSM standard. This alphabet should be supported by all MSs which support the SDS-TL protocol. Additional alphabets (including UCS2) may also be supported as options.

The 7-bit alphabet shall be as shown in table 29.39.

**Table 29.39: Alphabet table for GSM 7-bit alphabet**

|           |           |           |           | <b>b7</b> | 0        | 0        | 0        | 0        | 1        | 1        | 1        | 1        |
|-----------|-----------|-----------|-----------|-----------|----------|----------|----------|----------|----------|----------|----------|----------|
|           |           |           |           | <b>b6</b> | 0        | 0        | 1        | 1        | 0        | 0        | 1        | 1        |
|           |           |           |           | <b>b5</b> | 0        | 1        | 0        | 1        | 0        | 1        | 0        | 1        |
| <b>b4</b> | <b>b3</b> | <b>b2</b> | <b>b1</b> |           | <b>0</b> | <b>1</b> | <b>2</b> | <b>3</b> | <b>4</b> | <b>5</b> | <b>6</b> | <b>7</b> |
| 0         | 0         | 0         | 0         | <b>0</b>  | @        | Δ        | SP       | 0        | i        | P        | ¿        | p        |
| 0         | 0         | 0         | 1         | <b>1</b>  | £        | _        | !        | 1        | A        | Q        | a        | q        |
| 0         | 0         | 1         | 0         | <b>2</b>  | \$       | Φ        | "        | 2        | B        | R        | b        | r        |
| 0         | 0         | 1         | 1         | <b>3</b>  | ¥        | Γ        | #        | 3        | C        | S        | c        | s        |
| 0         | 1         | 0         | 0         | <b>4</b>  | è        | Λ        | α        | 4        | D        | T        | d        | t        |
| 0         | 1         | 0         | 1         | <b>5</b>  | é        | Ω        | %        | 5        | E        | U        | e        | u        |
| 0         | 1         | 1         | 0         | <b>6</b>  | ù        | Π        | and      | 6        | F        | V        | f        | v        |
| 0         | 1         | 1         | 1         | <b>7</b>  | ì        | Ψ        | '        | 7        | G        | W        | g        | w        |
| 1         | 0         | 0         | 0         | <b>8</b>  | ò        | Σ        | (        | 8        | H        | X        | h        | x        |
| 1         | 0         | 0         | 1         | <b>9</b>  | Ç        | Θ        | )        | 9        | I        | Y        | i        | y        |
| 1         | 0         | 1         | 0         | <b>10</b> | LF       | Ξ        | *        | :        | J        | Z        | j        | z        |
| 1         | 0         | 1         | 1         | <b>11</b> | Ø        | 1)       | +        | ;        | K        | Ä        | k        | ä        |
| 1         | 1         | 0         | 0         | <b>12</b> | ø        | Æ        | ,        | <        | L        | Ö        | l        | ö        |
| 1         | 1         | 0         | 1         | <b>13</b> | CR       | æ        | -        | =        | M        | Ñ        | m        | ñ        |
| 1         | 1         | 1         | 0         | <b>14</b> | À        | ß        | .        | >        | N        | Ü        | n        | ü        |
| 1         | 1         | 1         | 1         | <b>15</b> | à        | É        | /        | ?        | O        | Ş        | o        | ş        |

The following rules shall apply to the use of this alphabet:

- Control characters shall have the following meaning:

Code Meaning

LF Line Feed: Any characters following LF which are to be displayed shall be presented as the next line of the text message, commencing with the first character position;

CR Carriage Return: Any characters following CR which are to be displayed shall be presented as the current line of the text message, commencing with the first character position;

SP Space Character.

- If these characters are to be displayed within a message, each character shall be taken in turn and be placed in the next available space from left to right and from top to bottom.

#### 29.5.4.4 Time stamp

The Time stamp information element shall indicate as defined in table 29.40 the (approximate) creation time of the message. The information element is added to a message by the SwMI to allow the destination to evaluate the age of the message.

**Table 29.40: Time stamp information element contents**

| Information element   | Length | Type | C/O/M | Value   | Remark                           |
|---|--------|------|-------|---------|----------------------------------|
| Timeframe type  | 2      | 1    | M     | 0       | Undefined, application dependent |
|   |        |      |       | 1       | UTC                              |
|   |        |      |       | 2       | Local time, normal time          |
|   |        |      |       | 3       | Local time, daylight saving time |
| Reserved  | 2      | 1    | M     | 0       | See note                         |
| Month   | 4      | 1    | M     | 1 to 12 |                                  |
| Day   | 5      | 1    | M     | 1 to 31 |                                  |
| Hour  | 5      | 1    | M     | 0 to 23 |                                  |
| Minute  | 6      | 1    | M     | 0 to 59 |                                  |
| NOTE: This field is inserted to ensure that the following information elements are aligned to octet boundaries and so ease processing by the application. In the present document the field shall be set to "00 <sub>2</sub> ". |        |      |       |         |                                  |

#### 29.5.4.5 Timestamp used

The Timestamp used information element shall indicate as defined in table 29.41 if a timestamp is used in the PDU.

**Table 29.41: Timestamp used information element contents**

| Information element | Length | Value          | Remark                |
|---------------------|--------|----------------|-----------------------|
| Timestamp used      | 1      | 0 <sub>2</sub> | Timestamp not present |
|                     |        | 1 <sub>2</sub> | Timestamp present     |

### 29.5.5 Simple location system

#### 29.5.5.0 General

The simple location system protocol is intended to be a location system application, which does not require any transport mechanism to ensure delivery.

#### 29.5.5.1 Protocol sequences

Simple location system does not use any end-to-end acknowledgement (reporting) signalling. The only delivery mechanisms offered is the layer 2 acknowledge.

#### 29.5.5.2 PDU description tables

Simple location system does not use the SDS-TL data transfer service PDUs, but defines a protocol specific field to specify the data format, refer to clause 29.5.7. The basic SDS type-4 information element shall contain elements as defined in clause 29.5.5.3.

### 29.5.5.3 Simple location system PDU

- Response to: -
- Response expected: -
- Short description: This PDU shall be used to send location system SDS data.

**Table 29.42: Simple location system PDU contents**

| Information element           | Length   | Type | C/O/M | Remark                      |
|-------------------------------|----------|------|-------|-----------------------------|
| Protocol identifier           | 8        | 1    | M     | Value 00000011 <sub>2</sub> |
| Location system coding scheme | 8        | 1    | M     | As defined in table 29.44   |
| Location system data          | variable | 1    | M     |                             |

## 29.5.6 Location system using SDS-TL data transfer services

### 29.5.6.0 General

This location system protocol set offers end-to-end acknowledgement and/or storing/forwarding entity services in the SwMI.

### 29.5.6.1 Protocol sequences

The protocol sequences of location system messaging shall be the protocol sequences defined in clause 29.3.3.

### 29.5.6.2 PDU description tables

The location system protocol uses the full TL protocol. Additional information elements are present in the SDS-TRANSFER PDU.

### 29.5.6.3 Location system transfer SDU

The location system message transfer is done by use of an SDS-TRANSFER with additional information elements embedded in the user data portion of the SDS-TRANSFER. The location system SDU shall be encoded as defined in table 29.43.

**Table 29.43: Location system SDU contents**

| Information element           | Length   | Type | C/O/M | Remark                    |
|-------------------------------|----------|------|-------|---------------------------|
| Location system coding scheme | 8        | 1    | M     | As defined in table 29.44 |
| Location system data          | variable | 1    | M     |                           |

## 29.5.7 Location system coding scheme

For protocols carrying location system data, the location system coding scheme information element shall be as defined in table 29.44.

**Table 29.44: Location system coding scheme information element contents**

| Information element  | Length | Value   | Remark   |
|--|--------|---|--|
| Location system coding scheme  | 8      | 0000000 <sub>2</sub>                            | National Marine Electronics Association, see annex L |
|  |        | 0000001 <sub>2</sub>                            | RTCM SC-104, see annex L                             |
|  |        | 0000010 <sub>2</sub> to<br>0111111 <sub>2</sub> | Reserved   |
|  |        | 1000000 <sub>2</sub> to<br>1111110 <sub>2</sub> | Available for user application definition (see note) |
|  |        | 1111111 <sub>2</sub>                            | Reserved   |
| NOTE: Identities of these applications should be allocated by a central body in order to support interoperability. |        |   |  |

NOTE 1: This list only defines a subset of the available data coding schemes for location systems. The list should be expected to expand as more data coding schemes are adopted.

NOTE 2: TETRA defines a standardized location information transport protocol (LIP) that uses another protocol identifier than the "simple location system" or the "location system", refer to clauses 29.4.3.9, 29.5.12 and ETSI TS 100 392-18-1 [19].

## 29.5.8 Wireless Application Protocol (WAP)

### 29.5.8.0 General

Wireless Application Protocol (WAP) is a result of continuous work to define an industry wide standard for developing applications over wireless communication networks. The scope for the WAP working group is to define a set of standards to be used by service applications, refer to IETF RFC 1994 [34]. The upper layers of WAP will be independent of the underlying wireless network, while the data link layer might be adapted to specific features of underlying bearers. However, by keeping the data link layer interface, as well as the basic features, consistent global interoperability can be achieved using mediating gateways.

### 29.5.8.1 Protocol sequences

WAP need not use the SDS-TL data transfer services as those will only add overhead over the normal WAP operation. For WAP protocol sequences, the reader is referred to WAP 2.0 [i.9].

### 29.5.8.2 PDU description tables

WAP need not use the SDS-TL data transfer service PDUs as those will only add overhead, refer to clause 29.5.1.2. The minimum standardized information element of WAP is the Protocol Identifier. For all other aspects of WAP the reader is referred to WAP 2.0 [i.9].

## 29.5.9 Message with user data header (UDH)

### 29.5.9.0 General

The UDH protocol is based on (TP-UD) field defined in GSM specification for SMS (ETSI TS 123 040 [2]). This protocol is terminated in the application layer and uses SDS-TL transport service. The UDH is carried with the User Data parameter of the SDS-TRANSFER PDU as defined in table 29.14.

NOTE: "Field" in GSM specifications means same as "information element" in the present document.

### 29.5.9.1 Protocol sequences

The protocol sequences of UDH messaging shall be the unmodified protocol sequences defined in clause 29.3.3.

### 29.5.9.2 PDU description tables

The UDH protocol uses the full SDS-TL data transport service protocol. The UDH protocol defines additional information elements, which are transported in the SDS-TRANSFER PDU.

### 29.5.9.3 User Data Header transfer SDU

The text message transfer is done by use of an SDS-TRANSFER PDU with additional information elements embedded in the user data portion of the SDS-TRANSFER PDU. The SDU part as defined in table 29.45 shall be the user data in the SDS-TRANSFER PDU, refer to table 29.14.

**Table 29.45: UDH transfer SDU contents**

| Information element   | Length   | Type | C/O/M | Remark                                 |
|---|----------|------|-------|--|
| Time stamp used   | 1        | 1    | M     | As defined in table 29.41, see note 1. |
| Text coding scheme  | 7        | 1    | M     | As defined in table 29.29, see note 1. |
| Time stamp  | 24       |      | C     | As defined in table 29.40, see note 2. |
| User Data Header length   | 8        | 1    | M     | See note 3.                            |
| User Data Header information element  | Variable |      | C     | Repeatable, see note 4.                |
| Network layer user data   | Variable |      | C     | See note 5.                            |
| NOTE 1: These two elements can be processed together in order to keep byte alignment.   |          |      |       |  |
| NOTE 2: This information element shall be present only, when the Time stamp used indicates the presence of timestamp.   |          |      |       |  |
| NOTE 3: The User Data Header length information element shall indicate the number of octets within the User Data Header information element information elements, which follow and shall not include itself in its count.                       |          |      |       |  |
| NOTE 4: The User Data Header length indirectly defines how many User Data Header information element information elements are present as each User Data Header information element contains its length.   |          |      |       |  |
| NOTE 5: The Network layer user data information element may be present and the content depends on UDH information element ID meaning. The end of the Network layer user data information element is defined by the end of the SDS-TRANSFER PDU. |          |      |       |  |

### 29.5.9.4 UDH transfer SDU information elements

#### 29.5.9.4.1 User Data Header Information Element

The User Data Header information element information element shall be encoded as defined in table 29.46.

**Table 29.46: User Data Header information element information element contents**

| Information element   | Length   | Type | C/O/M | Remark      |
|---|----------|------|-------|-------------|
| UDH information element ID (1)  | 8        | 1    | M     | See note 1. |
| UDH information element length (1)  | 8        | 1    | M     | See note 2. |
| UDH information element data (1)  | Variable |      | C     | See note 3. |
| NOTE 1: See table 29.47.  |          |      |       |             |
| NOTE 2: The UDH information element length information element shall indicate the number of octets within its associated UDH information element data information element, which follows and shall not include itself in its count value. |          |      |       |             |
| NOTE 3: The content depends on UDH information element ID meaning.  |          |      |       |             |

The UDH information element ID information element shall be encoded as presented in table 29.47.

**Table 29.47: UDH information element ID information element contents**

| Information element        | Length | Value  | Remark  | Clause  |
|----------------------------|--------|--|---|---------|
| UDH information element ID | 8      | 00000000 <sub>2</sub>                          | Concatenated text message (8-Bit reference number)  | 29.5.10 |
|                            |        | 00000001 <sub>2</sub> to 00000111 <sub>2</sub> | Reserved (see note)                                 | -       |
|                            |        | 00001000 <sub>2</sub>                          | Concatenated text message (16-Bit reference number) | 29.5.10 |
|                            |        | 00001001 <sub>2</sub> to 11111111 <sub>2</sub> | Reserved (see note)                                 | -       |

NOTE: Defined in GSM specification for SMS (ETSI TS 123 040 [2]).

## 29.5.10 Concatenated text messaging

### 29.5.10.0 General

Concatenated text messaging uses the UDH protocol. It allows an application to concatenate several single SDS text messages to transfer one long text message. Each single message is a segment of the long text message. Segmentation and recombination of long text messages is done in the application layer.

### 29.5.10.1 Protocol sequences

The protocol sequences of concatenated text messaging shall be the unmodified protocol sequences defined in clause 29.3.3.

### 29.5.10.2 PDU description tables

The UDH protocol uses the full SDS-TL data transport service protocol. The UDH protocol defines additional information elements, which are transported in the SDS-TRANSFER PDU.

### 29.5.10.3 Concatenated text message transfer SDU

The concatenated text message transfer is done by use of an SDS-TRANSFER PDU with additional information elements embedded in the user data portion of the SDS-TRANSFER PDU. The SDU part as defined in table 29.48 shall be the user data in the SDS-TRANSFER PDU, refer to table 29.46.

NOTE: In the table 29.48 the User Data Header information element as defined in table 29.46 is presented as information elements of the Concatenated text message transfer SDU.

**Table 29.48: Concatenated text message transfer SDU contents**

| Information element                | Length   | Type | C/O/M | Remark                                 |
|------------------------------------|----------|------|-------|--|
| Time stamp used                    | 1        | 1    | M     | As defined in table 29.41 (see note 1) |
| Text coding scheme                 | 7        | 1    | M     | As defined in table 29.29 (see note 1) |
| Time stamp                         | 24       |      | C     | As defined in table 29.40 (see note 2) |
| User Data Header length            | 8        | 1    | M     |  |
| UDH information element ID         | 8        | 1    | M     |  |
| UDH information element length     | 8        | 1    | M     |  |
| Message reference number           | 8/16     |      | C     | (see note 3)                           |
| Maximum number of messages         | 8        | 1    | M     |  |
| Sequence number of current message | 8        | 1    | M     |  |
| User text (Text segment)           | Variable | 1    | M     | (see note 4)                           |

NOTE 1: These two elements can be processed together in order to keep byte alignment.  
NOTE 2: This information element shall be present only, when the Time stamp used indicates the presence of timestamp.  
NOTE 3: The length and value depends on the UDH information element ID see table 29.47 and clause 29.5.11.7.  
NOTE 4: The length of the User text is determined by the end of the User data in the SDS-TRANSFER PDU.

#### 29.5.10.4 Concatenated text message short form acknowledgement

The concatenated text messaging may use the SDS-SHORT REPORT PDU as defined in clause 29.4.4.4.

The destination MS can choose between the SDS-SHORT REPORT PDU and the SDS-REPORT PDU in the cases where the report types available in the short form will suffice, refer to clause 29.3.3.4.4.

If the receiving entity receives "delivery report request" information element value "message consumed report requested" or "message received and consumed report requested" in one or more of the SDS text messages within the concatenated SDS text message, the receiving entity should send only one SDS-SHORT-REPORT or SDS-REPORT PDU to report consumption of the concatenated text message. The receiving entity should not send separate consumption reports for the individual SDS text messages comprising the concatenated SDS text message.

NOTE 1: If the receiving entity receives the "delivery report request" information element value "message received and consumed report requested" in individual SDS text messages comprising the concatenated SDS text message, the receiving entity should acknowledge reception of the individual SDS text messages with separate PDUs and should report consumption of the concatenated SDS message with a further single PDU.

NOTE 2: The sending entity should include the same value of the "delivery report request" information element in each individual SDS text message comprising the concatenated SDS text message.

#### 29.5.11 Concatenated text messaging information elements

##### 29.5.11.1 Text coding scheme

See clause 29.5.4.1.

##### 29.5.11.2 Time stamp

See clause 29.5.4.4.

##### 29.5.11.3 Time stamp used

See clause 29.5.4.5.

##### 29.5.11.4 User data header length

See clause 29.5.9.3.

##### 29.5.11.5 UDH information element ID

The value shall be "Concatenated SDS text message (8 bit reference number)" or "Concatenated SDS text message (16 bit reference number)" as defined in table 29.47.

##### 29.5.11.6 UDH information element length

The value depends on the UDH information element ID. If the UDH information element ID is "Concatenated Text Message (8 bit reference number)" the value is 3 bytes. If the UDH information element ID is "Concatenated Text Message (16 bit reference number)" the value is 4 bytes.

### 29.5.11.7 Message reference number

The length depends on UDH information element ID. It shall contain modulo 256 counter for 8 bit length or modulo 65 536 for 16 bit indicating the reference number for a particular concatenated short message. This reference number shall remain constant for every short message, which makes up a particular concatenated short message.

### 29.5.11.8 Maximum number of messages

Maximum number of SDS text messages in the concatenated SDS text message. This octet shall contain a value in the range 0 to 255 indicating the total number of SDS text messages within the concatenated SDS text message. The value shall start at 1 and remain constant for every SDS text message, which makes up the concatenated SDS text message. If the value is zero then the receiving entity shall ignore the whole UDH information element.

### 29.5.11.9 Sequence number of current message

The Sequence number of current message shall contain a value in the range 0 to 255 indicating the sequence number of a particular SDS text message within the concatenated SDS text message. The value shall start at 1 and increment by one for every SDS text message sent within the concatenated SDS text message. If the value is zero or the value is greater than the value in octet 2 then the receiving entity shall ignore the whole UDH information element.

### 29.5.11.10 User text (Text segment)

The sender application is responsible for dividing a text message into a concatenated SDS text message. The receiver application is responsible for re-constructing the concatenated SDS text message.

## 29.5.12 Location information transport

### 29.5.12.1 General

The Location Information Protocol (LIP) is defined in ETSI TS 100 392-18-1 [19] and clauses 29.5.12.2 to 29.5.12.6 define how SDS-TL shall be used as a transportation mechanism for it. The location information protocol is described as an application using SDS-TL service at SDS-TL SAP, refer to 29.1.1. The location information protocol can use packet data at SND CP SAP as defined in clause 28. The use of packet data is outside the scope of the clauses 29.5.12.2 to 29.5.12.6 of the present document.

### 29.5.12.2 Protocol sequences at SDS-TL

The location information protocol does not use any end-to-end acknowledgement (reporting) signalling of the SDS-TL protocol. The only delivery mechanism at the transportation level is the layer 2 acknowledgement.

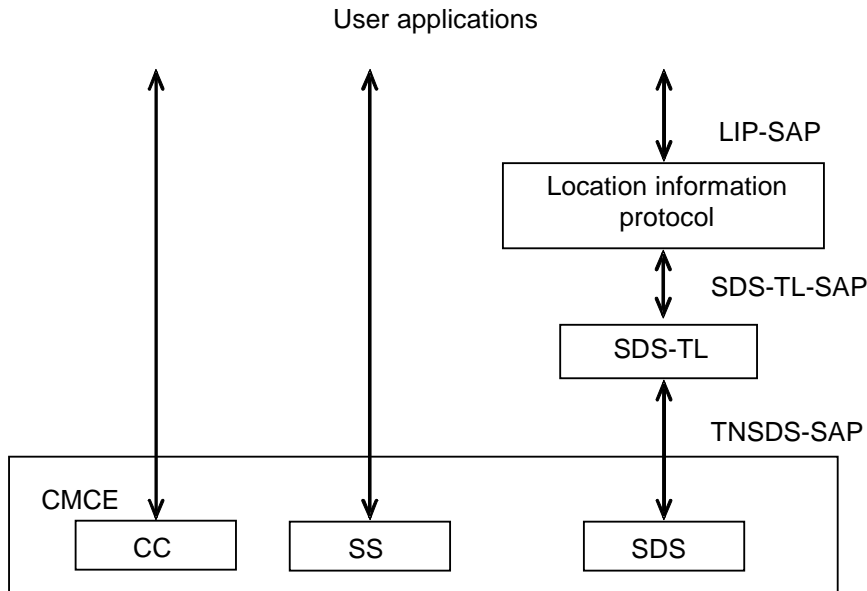

### 29.5.12.3 Location information protocol architecture

#### 29.5.12.3.1 System architecture

System architecture is described in ETSI TS 100 392-18-1 [19].

### 29.5.12.3.2 MS architecture

When the location information protocol (LIP) uses SDS-TL data transfer service figure 29.9 shows the position of the location information transport protocol in the MS protocol stack. The physical location of the location transport protocol and LIP-SAP may be imbedding into the user applications and is outside the the scope of the present document. A physical access to the LIP-SAP is outside the scope of the present document.

**Figure 29.9: LIP position in TETRA protocol stack**

Location information protocol adds a layer of protocol functionality that utilizes the SDS-TL.

The location information protocol can use services of the TNSDS-SAP via SDS-TL-SAP. The location information protocol shall run parallel to any other protocols utilizing SDS-TL without any interactions.

### 29.5.12.4 Addressing at SDS-TL

The addressing for the LIP shall use the basic SDS addressing without storing/forwarding entity addresses.

### 29.5.12.5 Location information transport protocol

ETSI TS 100 392-18-1 [19] defines the location information protocol.

### 29.5.12.6 SDS-TL overhead

The location information transport PDUs in the LIP shall use a PID value that is not utilizing SDS-TL transport service. The general content of the SDS type 4 user data part shall be as shown in table 29.49.

**Table 29.49: SDS type 4 user data contents for LIP protocol**

| Information element  | Length   | Type | C/O/M | Value | Remark                        |
|--|----------|------|-------|-------|-------------------------------|
| Protocol identifier  | 8        | 1    | M     |       | Location information protocol |
| Location information transport protocol PDU  | variable | 1    | M     |       | See note.                     |
| NOTE: Content of this information element is defined in ETSI TS 100 392-18-1 [19]. |          |      |       |       |                               |

## 29.5.13 Net assist protocol

### 29.5.13.1 General

The Net Assist Protocol (NAP) is defined in ETSI TS 100 392-18-2 [20] and clauses 29.5.9.2 to 29.5.9.6 define how SDS-TL shall be used as a transportation mechanism for it. The Net Assist Protocol is described as an application using SDS-TL service at SDS-TL SAP, refer to clause 29.1.1.

### 29.5.13.2 Protocol sequences at SDS-TL

The location information protocol does not use any end-to-end acknowledgement (reporting) signalling of the SDS-TL protocol. The only delivery mechanism at the transportation level is the layer 2 acknowledgement.

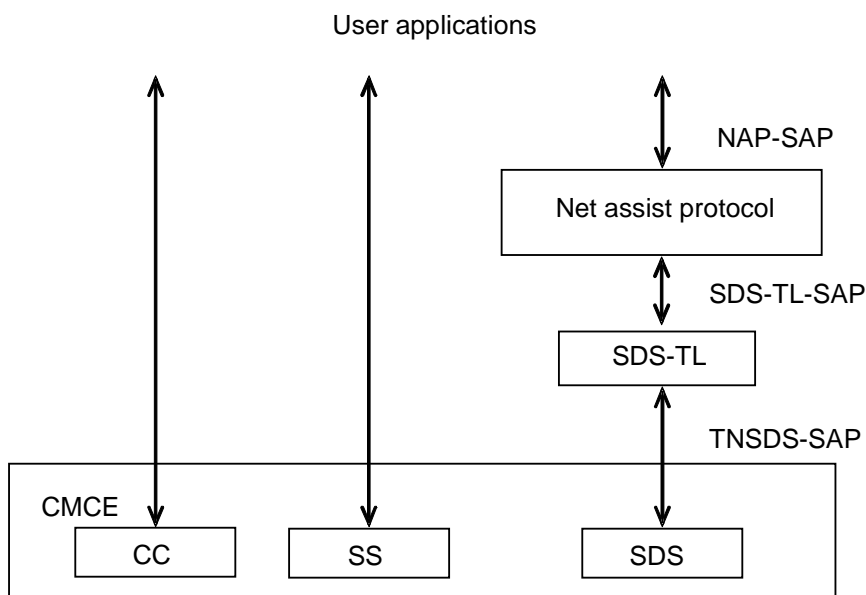

### 29.5.13.3 Location information protocol architecture

#### 29.5.13.3.1 System architecture

System architecture is described in ETSI TS 100 392-18-2 [20].

#### 29.5.13.3.2 MS architecture

When the Net Assist Protocol (NAP) uses SDS-TL data transfer service figure 29.10 shows the position of the location information transport protocol in the MS protocol stack. The physical location of the location transport protocol and NAP-SAP may be imbedding into the user applications and is outside the the scope of the present document. A physical access to the NAP-SAP is outside the scope of the present document.

**Figure 29.10: NAP position in TETRA protocol stack**

The Net Assist Protocol adds a layer of protocol functionality that utilizes the SDS-TL.

The Net Assist Protocol can use services of the TNSDS-SAP via SDS-TL-SAP. The Net Assist Protocol shall run parallel to any other protocols utilizing SDS-TL without any interactions.

### 29.5.13.4 Addressing at SDS-TL

The addressing for the Net Assist Protocol shall use the basic SDS addressing without storing/forwarding entity addresses.

### 29.5.13.5 Net Assist Protocol

ETSI TS 100 392-18-2 [20] defines the Net Assist Protocol.

### 29.5.13.6 SDS-TL overhead

The Net Assist Protocol PDUs in the NAP shall use a PID value that is not utilizing SDS-TL transport service. The general content of the SDS type 4 user data part shall be as shown in table 29.50.

**Table 29.50: SDS type 4 user data contents for NAP protocol**

| Information element   | Length   | Type | C/O/M | Value | Remark              |
|---|----------|------|-------|-------|---------------------|
| Protocol identifier   | 8        | 1    | M     |       | Net Assist Protocol |
| Net assist protocol PDU   | variable | 1    | M     |       | See note.           |
| NOTE: Content of this information element shall be as defined in ETSI TS 100 392-18-2 [20]. |          |      |       |       |                     |

## 29.5.14 Concatenation of SDS-TL messages protocol

### 29.5.14.1 Introduction

The concatenation of SDS-TL messages provides a means for delivering long messages using the SDS mechanism. As with UDH it concatenates several single SDS messages to transfer one long message, refer to clause 29.5.10. Each single message is a concatenation-part of the long message. The "parting" and recombination of long messages is done in a protocol layer above SDS-TL.

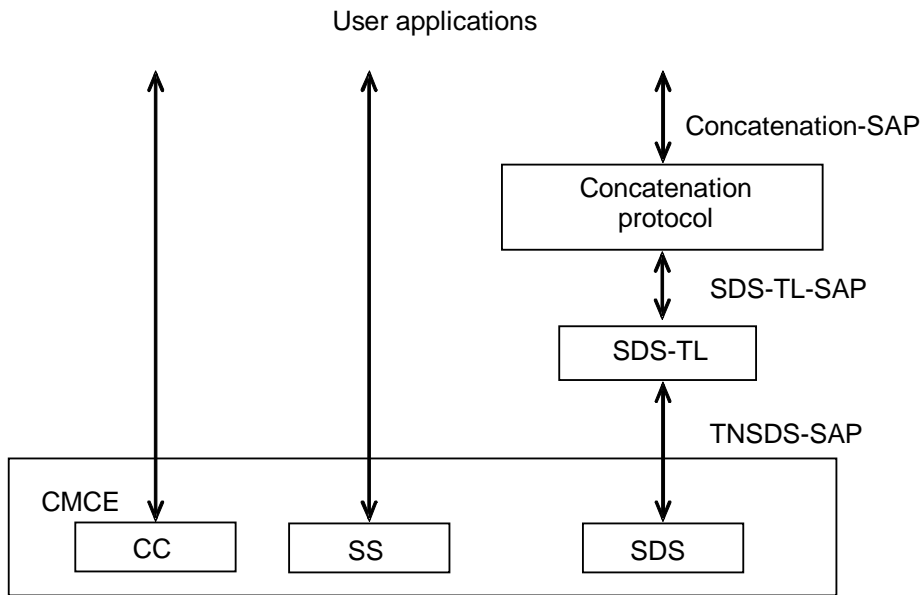

The concatenation protocol defined in clause 29.5.14 has the advantage over UDH that it can transfer messages of any PID, and so is not restricted to carrying solely text messages.

### 29.5.14.2 MS protocol stack

For the concatenation service presentation purpose a protocol stack is defined in figure 29.11.

The concatenation is done at the concatenation layer i.e. the PIDs indicating a concatenation are used to route SDS messages to the concatenation layer that performs the re-assembly of the long message. The re-assembled long SDS message is routed to the proper application indicated by the PID of the user information. It is outside the scope of the present document whether the concatenation layer is a part of the MS or TE.

Concatenated SDS messages may be end to end encrypted, however the method of the encryption is outside the scope of the present document.

**Figure 29.11: Concatenation protocol stack**

### 29.5.14.3 Concatenation service

#### 29.5.14.3.1 General overview

Concatenation service as defined in clause 29.5.14 accepts a long user message from upper protocol layers as a single message. The concatenation layer forms multiple SDS-TL messages from that single message and sends those using the same SDS-TL service as defined in the long user message. The receiving entity re-assembles the multiple SDS-TL messages into a single long message and passes that to the upper protocol layers for user.

On the network point of view those multiple SDS-TL messages are normal SDS-TL messages and the network transports those without any concatenation specific actions.

The present concatenation service provides a minor limitation compared to the SDS-TL service and does not support user data in report messages.

#### 29.5.14.3.2 Concatenation service primitives

The concatenation layer provides almost the same service primitives as the SDS-TL layer modified so that a Concatenation reference is used instead of the Message reference. For the presentation purposes new service primitives are defined for the concatenation service although the basic services are the same as for the SDS-TL.

Services at the Concatenation-SAP are:

**Concatenation-TRANSFER request:** the primitive shall be used by the Concatenation entity to send data to a peer entity.

**Concatenation-TRANSFER indication:** the primitive shall be used by the Concatenation entity to pass data, which has been received from a peer entity.

Table 29.51 gives parameters for the Concatenation-TRANSFER primitives, when no forwarding entity is used.

**Table 29.51: Parameters for the Concatenation-TRANSFER primitive without forwarding addressing**

| Parameter  | Request        | Indication   |
|--|----------------|--------------|
| Access priority  | O              | -            |
| Traffic stealing   | O              | -            |
| Area selection   | O              | -            |
| Called party   | (see note 1)   | (see note 5) |
| Called party SNA   | C (see note 2) | -            |
| Called party SSI   | C (see note 2) | M            |
| Called party extension   | C (see note 2) | M            |
| External subscriber number (called party)  | O              | -            |
| Received address type  | -              | O            |
| Calling party  | - (see note 3) | (see note 6) |
| Calling party SSI  | -              | M            |
| Calling party extension  | -              | M            |
| External subscriber number (calling party)   | -              | O            |
| Protocol identifier (P PID)  | M              | M            |
| Delivery report request  | M              | M            |
| Service selection  | M              | -            |
| Short form report  | -              | M            |
| Forward control  | O              | O            |
| Validity period  | O              | O            |
| Concatenation reference handle   | M              | -            |
| Concatenation reference  | -              | M            |
| User data (see notes 7 and 8)  | O              | O            |
| User data is not complete (see note 8)   | -              | O            |
| NOTE 1: This parameter shall indicate the destination entity address.  |                |              |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                |              |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                |              |
| NOTE 4: Void.  |                |              |
| NOTE 5: This parameter value shall indicate "Called party SSI" and "Called party extension".   |                |              |
| NOTE 6: This parameter value shall indicate "Calling party SSI" and "Calling party extension".   |                |              |
| NOTE 7: User data (payload) may contain for some payload protocols a timestamp as a part of the SDS-TL protocol.   |                |              |
| NOTE 8: The user data parameter may be organized to indicate the presence and location of missing parts of the concatenated message, refer to clauses 29.5.14.7.2 and 29.5.14.7.3. |                |              |

Table 29.52 gives parameters for the Concatenation-TRANSFER primitives, when a forwarding entity is used.

**Table 29.52: Parameters for the Concatenation-TRANSFER primitive with forwarding addressing**

| Parameter   | Request        | Indication      |
|---|----------------|-----------------|
| Access priority   | O              | -               |
| Traffic stealing  | O              | -               |
| Area selection  | O              | -               |
| Called party:   | (see note 1)   | (see note 6)    |
| Called party SNA  | C (see note 2) | -               |
| Called party SSI  | C (see note 2) | M               |
| Called party extension  | C (see note 2) | M               |
| External subscriber number  | O (see note 1) | -               |
| Received address type   | -              | O               |
| Calling party:  | - (see note 3) | (see note 7)    |
| Calling party SSI   | -              | C (see note 8)  |
| Calling party extension   | -              | C (see note 8)  |
| External subscriber number (calling party)  | -              | O (see note 9)  |
| Protocol identifier (P PID)   | M              | M               |
| Delivery report request   | M              | M               |
| Service selection   | M              | -               |
| Short form report   | -              | M               |
| Forward control   | M              | M               |
| Validity period   | M              | O               |
| Forward address:  | (see note 4)   | (see note 10)   |
| Forward address SNA   | C (see note 5) |                 |
| Forward address SSI   | C (see note 5) | C (see note 11) |
| Forward address extension   | C (see note 5) | C (see note 11) |
| External subscriber number  | C (see note 5) | C (see note 11) |
| Concatenation reference handle  | M              | -               |
| Concatenation reference   | -              | M               |
| User data (see notes 12 and 13)   | O              | O               |
| User data is not complete (see note 13)   | -              | O               |
| NOTE 1: This parameter shall indicate the forwarding entity address to which the message is going for delivery to the destination.  |                |                 |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.   |                |                 |
| NOTE 3: Lower protocol layers will add the calling party identity.  |                |                 |
| NOTE 4: This information element shall indicate the final destination entity address.   |                |                 |
| NOTE 5: This parameter shall be present as defined by the forward address type identifier parameter.  |                |                 |
| NOTE 6: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination.  |                |                 |
| NOTE 7: This parameter shall indicate the forwarding entity address to which sent the message on behalf of the original source.   |                |                 |
| NOTE 8: This parameter shall be present as defined by the calling party type identifier parameter.  |                |                 |
| NOTE 9: This parameter shall indicate the storing/forwarding entity address to which sent the message on behalf of the original source.   |                |                 |
| NOTE 10: This parameter shall indicate the original source entity address.  |                |                 |
| NOTE 11: This parameter shall be present as defined by the forward address type identifier parameter.   |                |                 |
| NOTE 12: User data (payload) may contain for some payload protocols a timestamp as a part of the SDS-TL protocol.   |                |                 |
| NOTE 13: The user data parameter may be organized to indicate the presence and location of missing parts of the concatenated message, refer to clauses 29.5.14.7.2 and 29.5.14.7.3. |                |                 |

**Concatenation-REPORT request:** the primitive shall be used by the Concatenation entity to send reports to a peer entity.

**Concatenation-REPORT indication:** the primitive shall be used by the Concatenation entity to pass reports, which has been received from a peer entity.

Table 29.53 gives parameters for the Concatenation-REPORT primitives, when no forwarding entity is used.

**Table 29.53: Parameters for the Concatenation-REPORT primitive (no forwarding)**

| Parameter  | Request        | Indication        |
|--|----------------|-------------------|
| Access priority  | O              | -                 |
| Traffic stealing   | O              | -                 |
| Area selection   | O              | -                 |
| Called party:  | See note 1     | See note 4        |
| Called party SNA   | C (see note 2) | -                 |
| Called party SSI   | C (see note 2) | M                 |
| Called party extension   | C (see note 2) | M                 |
| External subscriber number (called party)  | O              | -                 |
| Calling party:   | See note 3     | See notes 5 and 6 |
| Calling party SSI  | -              | M                 |
| Calling party extension  | -              | M                 |
| External subscriber number (calling party)   | -              | O (see note 6)    |
| Protocol identifier (P PID)  | M              | M                 |
| Acknowledgement required   | M              | M                 |
| Delivery status  | M              | M                 |
| Concatenation reference handle   | -              | O (see note 7)    |
| Concatenation reference  | M              | M                 |
| User data  | - (see note 8) | - (see note 8)    |
| NOTE 1: This parameter shall indicate the destination entity address.  |                |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This parameter shall indicate the destination entity address.                         |                |                   |
| NOTE 5: This parameter shall value indicate "Calling party SSI" and "Calling party extension".   |                |                   |
| NOTE 6: This parameter shall indicate the source entity address.   |                |                   |
| NOTE 7: This parameter shall be used in the first Concatenation-REPORT indication to a Concatenation-TRANSFER request, unless provided in a Concatenation-TNSDS-REPORT indication. |                |                   |
| NOTE 8: The present concatenation service does not support user data.  |                |                   |

Table 29.54 gives parameters for the Concatenation-REPORT primitives, when a forwarding entity is used.

**Table 29.54: Parameters for the Concatenation-REPORT primitive (forwarding)**

| Parameter  | Request         | Indication        |
|--|-----------------|-------------------|
| Access priority  | O               | -                 |
| Traffic stealing   | O               | -                 |
| Area selection   | O               | -                 |
| Called party   | See note 1      | See note 4        |
| Called party SNA   | C (see note 2)  | -                 |
| Called party SSI   | C (see note 2)  | M                 |
| Called party extension   | C (see note 2)  | M                 |
| External subscriber number   | O (see note 1)  | -                 |
| Calling party  | See note 3      | See notes 5 and 6 |
| Calling party SSI  | -               | M                 |
| Calling party extension  | -               | M                 |
| External subscriber number (calling party)   | -               | O (see note 6)    |
| Protocol identifier (P PID)  | M               | M                 |
| Acknowledgement required   | M               | M                 |
| Delivery status  | M               | M                 |
| Storage/forward control  | M               | M                 |
| Validity period  | M               | O                 |
| Forward address:   | See note 8      | See note 10       |
| Forward address SNA  | C (see note 9)  |                   |
| Forward address SSI  | C (see note 9)  | C (see note 11)   |
| Forward address extension  | C (see note 9)  | C (see note 11)   |
| External subscriber number   | C (see note 9)  | C (see note 11)   |
| Concatenation reference handle   | -               | O (see note 7)    |
| Concatenation reference  | M               | M                 |
| User data  | - (see note 12) | - (see note 12)   |
| NOTE 1: This parameter shall indicate the address of the forwarding entity which sent the reported message on behalf of the original source.                                       |                 |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                 |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                 |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination.   |                 |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".   |                 |                   |
| NOTE 6: This parameter shall indicate the address of the forwarding entity which sent the Concatenation-REPORT indication on behalf of the original destination.                   |                 |                   |
| NOTE 7: This parameter shall be used in the first Concatenation-REPORT indication to a Concatenation-TRANSFER request, unless provided in a Concatenation-TNSDS-REPORT indication. |                 |                   |
| NOTE 8: This information element shall indicate the address of the final destination entity.   |                 |                   |
| NOTE 9: This parameter shall be present as defined by the forward address type identifier parameter.   |                 |                   |
| NOTE 10: This parameter shall indicate the address of the original source entity.  |                 |                   |
| NOTE 11: This parameter shall be present as defined by the forward address type identifier parameter.  |                 |                   |
| NOTE 12: The present concatenation service does not support user data.   |                 |                   |

**Concatenation-ACK request:** the primitive may be used by the concatenation entity to acknowledge reports from a peer entity. The Concatenation-ACK request is used to acknowledge unsolicited reports (consumed message) or reports which may have been stored in the SwMI or at a storing/forwarding entity.

**Concatenation-ACK indication:** the primitive may be used by the concatenation entity to pass to the concatenation entity report acknowledgements, which has been received from a peer entity or generated by the SwMI or a storing/forwarding entity.

NOTE 1: The Concatenation-ACK request and Concatenation-ACK indication service primitives may be hidden from user application.

Table 29.55 gives parameters for the Concatenation-ACK primitives, when no forwarding entity is used.

**Table 29.55: Parameters for the Concatenation-ACK primitive (no forwarding)**

| Parameter  | Request        | Indication        |
|--|----------------|-------------------|
| Access priority  | O              | -                 |
| Traffic stealing   | O              | -                 |
| Area selection   | O              | -                 |
| Called party   | See note 1     | See note 4        |
| Called party SNA   | C (see note 2) | -                 |
| Called party SSI   | C (see note 2) | M                 |
| Called party extension   | C (see note 2) | M                 |
| External subscriber number (called party)  | O              | -                 |
| Calling party  | See note 3     | See notes 5 and 6 |
| Calling party SSI  | -              | M                 |
| Calling party extension  | -              | M                 |
| External subscriber number (calling party)   | -              | O (see note 6)    |
| Protocol identifier (P PID)  | M              | M                 |
| Delivery status  | M              | M                 |
| Concatenation reference  | M              | M                 |
| NOTE 1: This parameter shall indicate the destination entity address.  |                |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This parameter shall indicate the destination entity address. |                |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".   |                |                   |
| NOTE 6: This parameter shall indicate the source entity address.   |                |                   |

Table 29.56 gives parameters for the Concatenation-ACK primitives, when a storing/forwarding entity is used.

**Table 29.56: Parameters for the Concatenation-ACK primitive (storing/forwarding)**

| Parameter  | Request        | Indication        |
|--|----------------|-------------------|
| Access priority  | O              | -                 |
| Traffic stealing   | O              | -                 |
| Area selection   | O              | -                 |
| Called party:  | See note 1     | See note 4        |
| Called party SNA   | C (see note 2) | -                 |
| Called party SSI   | C (see note 2) | M                 |
| Called party extension   | C (see note 2) | M                 |
| External subscriber number   | O (see note 1) | -                 |
| Calling party:   | See note 3     | See notes 5 and 6 |
| Calling party SSI  | -              | M                 |
| Calling party extension  | -              | M                 |
| External subscriber number (calling party)   | -              | O (see note 6)    |
| Protocol identifier (P PID)  | M              | M                 |
| Delivery status  | M              | M                 |
| Concatenation reference  | M              | M                 |
| NOTE 1: This parameter shall indicate the storing/forwarding entity address from which the acknowledged report message was received.       |                |                   |
| NOTE 2: This parameter shall be present as defined by the called party type identifier parameter.  |                |                   |
| NOTE 3: Lower protocol layers will add the calling party identity.   |                |                   |
| NOTE 4: This parameter value shall indicate "Called party SSI" and "Called party extension". This identity shall indicate the destination. |                |                   |
| NOTE 5: This parameter value shall indicate "Calling party SSI" and "Calling party extension".   |                |                   |
| NOTE 6: This parameter shall indicate the storing/forwarding entity address to which the acknowledged report message was originally sent.  |                |                   |

**Concatenation-TNSDS-REPORT indication:** the primitive shall be used to indicate whether a Concatenation-ACK request, a Concatenation-TRANSFER request, a Concatenation-REPORT request, or a Concatenation-UNITDATA request has been either transmitted successfully or transmission have failed. The parameters are defined in table 29.57.

NOTE 2: This is a local information that is based on the LLC acknowledgements.

**Table 29.57: Parameters for the Concatenation-TNSDS-REPORT primitive**

| Parameter                      | Indication |
|--------------------------------|------------|
| Transfer result                | M          |
| Concatenation reference handle | M          |
| Concatenation reference        | O          |

**Concatenation-UNITDATA request:** the primitive shall be used to send user defined data-4 to a peer entity, when the SDS-TL data transfer services are not used.

**Concatenation-UNITDATA indication:** the primitive shall be used to receive user defined data-4 from a peer entity, when the SDS-TL data transfer services are not used.

The parameters are defined in table 29.58.

**Table 29.58: Parameters for the Concatenation-UNITDATA primitive**

| Parameter   | Request        | Indication     |
|---|----------------|----------------|
| Access priority   | O              | -              |
| Traffic stealing  | O              | -              |
| Area selection  | O (see note 4) | -              |
| Called party type identifier  | M              | -              |
| Called party SNA  | C (see note 1) | -              |
| Called party SSI  | C (see note 1) | M              |
| Called party extension  | C (see note 1) | O (see note 2) |
| Called party address type   | -              | O              |
| External subscriber number (called)   | O              | -              |
| Calling party:  |                |                |
| Calling party SSI   | -              | M              |
| Calling party extension   | -              | O (see note 2) |
| External subscriber number (calling)  | -              | O              |
| Protocol identifier (P PID)   | M              | M              |
| Concatenation handle  | M              | -              |
| Concatenation reference   | -              | M              |
| User defined data-4   | M (see note 3) | C (see note 3) |
| User data is not complete   | -              | O              |
| NOTE 1: Depending on the value of called party type identifier.   |                |                |
| NOTE 2: If not present, the user application shall assume that the address extension is the MNI of the current network.   |                |                |
| NOTE 3: This parameter is modified by the Concatenation and SDS-TL protocols and it contains always concatenation control and a user data protocol identifier, and is available via the Concatenation-SAP, refer to clause 29.5.14.2. |                |                |
| NOTE 4: Usage of this parameter is defined in ETSI EN 300 392-12-8 [14].  |                |                |

**Concatenation-MANAGEMENT request:** the primitive shall be used to set concatenation specific service parameters.

**Concatenation-MANAGEMENT indication:** the service shall be used to inform user application on the concatenation specific service parameters.

**Table 29.59: Parameters for the Concatenation-MANAGEMENT primitive**

| Parameter                                   | Request | Indication |
|---|---------|------------|
| Maximum concatenated message length         | O       | O          |
| Concatenation part size                     | O       | O          |
| Maximum number of concatenation parts       | O       | O          |
| Timeout for concatenation message reception | O       | O          |
| Acknowledgement control                     | O       | O          |
| Re-sending control                          | O       | O          |

### 29.5.14.3.3 Concatenation service primitive parameters

Parameters defined in clause 29.2.3 are applicable for the concatenation service primitive parameters. In addition following parameters are defined.

Acknowledgement control =

- Direct sending
  - No acknowledgement of concatenation parts
  - All concatenation parts acknowledged
  - Only last concatenation part acknowledged
- Store and forward sending
  - No acknowledgement of concatenation parts
  - All concatenation parts acknowledged
  - Only last concatenation part acknowledged

NOTE 1: The acknowledgement in the last concatenation part is a request for whole concatenated message acknowledgement, refer to clause 29.5.14.8.1.

Concatenation reference =

- Short concatenation reference 0 to 15;
- Extended concatenation reference 16 to 4 095.

NOTE 2: The short concatenation reference values can be considered to be a part of the extended concatenation references i.e. belong to a single numbering resource.

Concatenation reference handle =

- 0 to 4 095, a local handle to the actual concatenation reference. The mapping between a concatenation reference and a concatenation reference handle is a local issue and outside the scope of the present document.

Concatenation part size =

- Size of individual concatenation parts;

NOTE 3: Concatenation part size may be used in the calculation of the total message size, if the concatenation parts are of the same size.

- Use air interface optimized concatenation part size.

NOTE 4: How air interface optimized concatenation part size is defined is outside the scope of the present document.

NOTE 5: The concatenation part size sets indirectly how many timeslots will be used in fragmentation of the basic link service at the MAC layer.

Maximum concatenated message length =

- Network or application dependent.

Maximum number of concatenation-parts =

- Network dependent number (more than one);

NOTE 6: How MS or user application knows the network dependent number is outside the scope of the present document.

NOTE 7: The maximum number of concatenation-parts may be defined depend on the sizes of the concatenation parts and/or on the maximum length of the concatenated message.

Protocol identifier (P PID) =

- Payload protocol (P PID)

NOTE 8: This parameter is not used by the concatenation protocol, but is presented to remind that it is not the C PID that is not presented in any of the concatenation service primitives. It is the P PID of the payload, refer to clause 29.5.14.5 and for the value, refer to clause 29.4.3.9.

Re-sending control =

- No re-sending of failed concatenation parts
- Use application dependent re-sending algorithm

NOTE 9: Re-sending control may be applicable only, if acknowledgements are requested for individual concatenation parts, refer to clause 29.5.14.8.1.

Timeout for concatenation message reception =

NOTE 10: The value is outside the scope of the present document, could be 30 s to 10 min.

Transfer result =

- Success
- Failure, some concatenation parts are sent successfully
- Failure, transmission of all concatenation parts has failed

#### 29.5.14.4 Concatenation protocol

The present document defines the concatenation of the user SDS message containing user data. No protocol or PDUs (SDS messages) are defined for retransmission requests of missing concatenation-parts.

NOTE 1: The protocol can be enhanced in a later version of the present document to include acknowledgements and retransmission of missed concatenation-parts in the concatenation protocol.

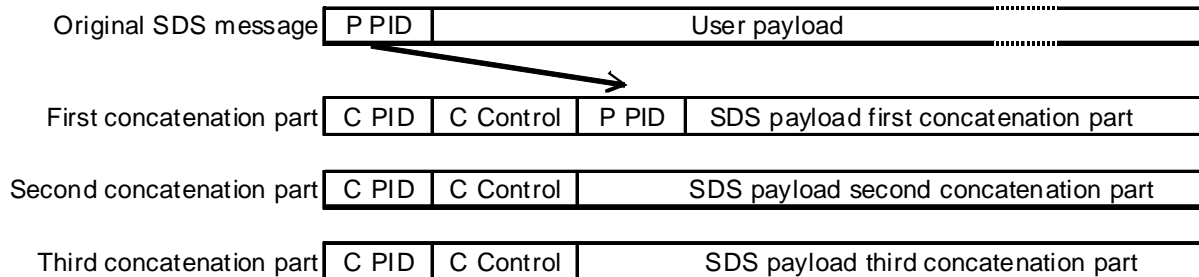

NOTE 2: The protocol description assumes that the user application is using SDS-TL messages in the same manner as without concatenation i.e. on the user's point of view a concatenated message is a single message and the concatenation layer hides actions inside the SDS-TL layer. In real implementations application and concatenation may be combined together.

The concatenation can be used with or without SDS-TL data transport service protocol as defined by the PID value of the concatenation indication. The PID value of the concatenation indication shall define whether SDS-TL service is used or not and shall indicate the same SDS-TL service as the original SDS message.

### 29.5.14.5 Concatenated message structures

The concatenated messages are divided into concatenation parts. The first concatenation part shall contain the PID of the user payload message.

Figure 29.12 presents how a long SDS message without SDS-TL service shall be divided into concatenation parts. The concatenation PID (C PID) of each SDS-TL message containing a concatenation part shall indicate that SDS-TL service is not used.

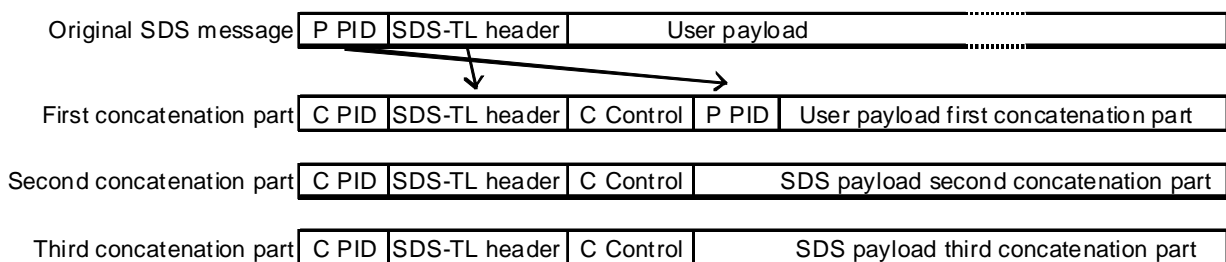

**Figure 29.12: Concatenation of SDS-TL message without SDS-TL service**

Figure 29.13 presents how a long SDS message with SDS-TL service is divided into concatenation parts. The PID of the user payload (indicating usage of SDS-TL service) shall be in the first concatenation part (P PID). The PID (C PID) of each SDS-TL message containing a concatenation part shall indicate that SDS-TL service is used and shall be followed by a SDS-TL header. Each SDS-TL header shall contain a different Message reference value for each concatenation part.

The underlying SDS-TL layer will consider the C Control and the P PID in the first concatenation part to be user payload in the SDS-TL messages and will not study those information elements.

NOTE 1: Although the payload PID (P PID) in a concatenated message indicates usage of SDS-TL service the user payload follows directly the P PID and the SDS-TL header is not repeated after the P PID as the concatenation protocol places that P PID into the user payload of the SDS-TL service.

NOTE 2: If the SDS-TRANSFER PDU Message reference value were the same in multiple SDS-TRANSFER PDUs, then the receiving entity would use all but one of the SDS-TRANSFER PDUs as repetitions. Also optional acknowledgements require unique values of the Message reference.

**Figure 29.13: Concatenation of SDS-TL message with SDS-TL service**

### 29.5.14.6 General on concatenated messages transport

The sending entity shall divide each user message into concatenation-parts, add to each concatenation-part a concatenation PID indicating whether the SDS-TL service is used or not, copy SDS-TL header and add Concatenation control information element, refer to clause 29.5.14.5.

The **concatenation control** information elements mark and identify SDS-TL messages that form a concatenated message, refer to table 29.60.

The **concatenation message reference** that is a combination of the Short concatenation reference information element and the Concatenation reference extension information element providing either four bits or 12 bits long reference number. That number shall be the same in all concatenation parts of a single user message. The sending entity shall manage concatenation reference numbers so that at least the combination of the concatenation reference number, sender's address and recipient's address is unique over a time that prevents mixing concatenation parts of different messages.

NOTE 1: Where the numbering scheme makes use of the long concatenation reference for higher numbered parts of the message, the lowest values (0 to 15) may be sent using either short or long concatenation references.

NOTE 2: The Message reference information element value in the SDS-TL data transfer service part of the SDS-TRANSFER PDU is independent of the Concatenation reference, refer to clause 29.5.14.4.

The **Number of concatenation-parts** shall indicate how many concatenation-parts form a single user message.

The **Sequence number of the current concatenation-part** shall define the position of the concatenation-part in the user message.

The concatenation-parts shall be sent in the numerical order of the concatenation-part numbers. The receiving entity shall not assume that the concatenation-part will arrive in the concatenation-part number order as some of the network elements may not keep them in order due to various reasons. The network elements need not to study the concatenation control information elements of the concatenation-parts.

The radio interface protocol may generate multiple copies of concatenation-parts and the receiving entity shall suppress extra concatenation-parts at the re-assembly.

A maximum of 5 to 10 concatenation-parts is recommended (to assist with reliability of message delivery, when using basic link). Whether a network sets a limit to the number of concatenation parts or total length of the user message and how many long messages a user may send is outside the scope of the present protocol.

The sending entity should divide each user message into suitably sized concatenation-parts to fit into available MAC layer PDUs and timeslot sizes. It is outside of the present document how SDS-TL layer knows which concatenation-part sizes are optimum in each situation.

NOTE 3: This will vary according to the type of channel and modulation employed on the channel.

## 29.5.14.7 Concatenated messages transport without SDS-TL service

### 29.5.14.7.1 Sending concatenated SDS-TL messages without SDS-TL service

The sending entity shall divide each user message into concatenation-parts, refer to clause 29.5.14.6 and send concatenation-parts as independent SDS messages.

### 29.5.14.7.2 Receiving concatenated SDS-TL messages without SDS-TL service

When all concatenation-parts have been received the receiving entity shall remove the concatenation PID and the Concatenation control information elements and shall re-assemble the concatenation-parts into a SDS message and pass it to the higher layer application. It is outside the scope of the present document whether or when a partially received concatenated message is forwarded to a higher layer application.

The radio interface protocol may generate multiple copies of concatenation-parts and the receiving entity shall suppress extra concatenation-parts at the re-assembly.

### 29.5.14.7.3 Acknowledgement of concatenated SDS-TL messages without SDS-TL service

Concatenation layer does not add any acknowledgements to the SDS-TL (Type 4 SDS).

### 29.5.14.7.4 Concatenated message lifetime

The concatenation protocol does not contain any control of message lifetime. It is recommended that lifetime of concatenated messages sent without an SDS-TL service is considered to be quite limited. Exact lifetime is outside the scope of the present document.

### 29.5.14.7.5 Exceptional conditions

The present concatenation protocol does not define any protocol for exceptional situations for transport without SDS-TL service.

NOTE: Future versions of the present protocol may add acknowledgements or failure indications into the concatenation protocol as a part of the concatenation control.

## 29.5.14.8 Concatenated messages transport with SDS-TL transport service

### 29.5.14.8.1 Acknowledgements in transport of concatenated SDS-TL messages

The SDS-TL provides forwarding, storage and acknowledgement services. The concatenation protocol can use the SDS-TL transport acknowledgement services for its internal purposes and for the service user purposes.

The concatenation layer may use SDS-TL acknowledgements to acknowledge individual concatenation-parts. In order to differentiate concatenation-part acknowledgement and whole concatenated message acknowledgements a new value of the Delivery status information element "Concatenation-part receipt acknowledged by destination" is defined.

The Delivery report request information element value "Message received report requested" in the SDS-TRANSFER PDU has a double function in the concatenation protocol:

- in any other than in the last concatenation-part it requests report of reception of that concatenation part; and
- in the last concatenation-part it in addition requests a report of reception of the whole concatenated message.

The Message consumed report request is used for concatenation service at the same manner as in SDS-TL service modified so that a consumption of the whole concatenated message will be reported.

### 29.5.14.8.2 Sending concatenated SDS-TL messages with SDS-TL service

The sending entity shall divide each user message into concatenation-parts, refer to clause 29.5.14.6 and send concatenation-parts as independent SDS-TRANSFER PDUs. Each SDS-TRANSFER PDU shall have a different Message reference value within a single concatenated message.

NOTE 1: A unique value of the SDS-TL Message reference is required with a single concatenated message as otherwise the receiving entity keeps only one of the colliding concatenation-parts. The SDS-TL Message reference needs also be unique between multiple concatenated messages, if reports are requested and multiple concatenated messages are in transit at the same time, because as the reports do not contain any concatenation message reference.

When the sending entity asks for a whole concatenated message received report, then it shall use in all but the last concatenation-part Delivery report request information element value "No delivery report requested" and in the last concatenation-part value "Message received report requested". In the last concatenation part the sending entity may also use Delivery report request information element values "Message consumed report requested" and "Message received and consumed report requested". By this the Concatenation reference and the SDS-TL Message reference are linked together inside the concatenation layer and the SDS-TL Message reference is used for acknowledgement purposes.

When the sending entity asks reception reports of individual concatenation parts, then it shall use in all concatenation parts Delivery report request information element value "Message received report requested". In the last concatenation part the sending entity may also use Delivery report request information element value "Message received and consumed report requested".

NOTE 2: When a message received report is requested in the last concatenation-part, then the whole concatenated message reception report is requested instead of reception of the last concatenation part due to the limitations of the possible request values.

NOTE 3: The usage of the "Message received and consumed report requested" in the last concatenation-part may be advantageous as a loss of at least the last concatenation-part may be identified faster than using only "Message consumed report request". It also may save some air interface resources as fewer reports will be used.

When the sending entity receives SDS-REPORT PDU to the last concatenation part acknowledging the whole concatenated message the sending entity shall pass it to the user application using the corresponding Concatenation reference.

If an SDS-TL delivery report is requested for each concatenation-part by "Message received report requested" and sending entity has not received a report with Delivery status value "SDS receipt acknowledged by destination" or "SDS consumed by destination" the sending entity may re-send the concatenation-part or parts for which it has not received a report with Delivery status value "Concatenation-part receipt acknowledged by destination". The re-sending strategy may depend on the served application, and is instructed by the re-sending control parameter, refer to clause 29.5.14.3.3.

#### 29.5.14.8.3 Receiving concatenated SDS-TL messages with SDS-TL service

When all concatenation-parts have been received the receiving entity shall remove the concatenation PID and the Concatenation control information elements and shall re-assemble the concatenation-parts into a concatenation message and pass it to the higher layer application using Concatenation-TRANSFER indication. It is outside the scope of the present document whether or when a partially received concatenated message is forwarded to a higher layer application.

The following clauses define how concatenation layer reacts to the individual SDS-TRANSFER PDUs.

Upon receiving a concatenation-part with Delivery report request with value "Message received report requested" or "Message received and consumed report requested" the concatenation entity acts:

- If the whole concatenated message is received, but the message is not yet consumed or consumption report is not requested, then it shall send a report with Delivery status value "SDS receipt acknowledged by destination".

NOTE 1: The concatenation layer may wait for consumption indication before sending a reception report and save some air interface resources as only a consumption report will be sent. The waiting time is outside the scope of the present document.

- If the whole concatenated message is received and has been consumed and consumption report is requested, then it shall send a report with Delivery status value "SDS consumed by destination" and shall not send another report to indicate reception.
- If the whole concatenated message is not received, then it shall send a report with Delivery status value "Concatenation-part receipt acknowledged by destination".

Upon receiving a concatenation-part with Delivery report request with value "Message consumed report requested" the concatenation entity acts:

- If the whole concatenated message is received and has been consumed, then it shall send an SDS-REPORT PDU with Delivery status value "SDS consumed by destination".

NOTE 2: The SDS-REPORT PDU refers to the SDS-TL message reference that was in the concatenation part that contained the Delivery report request with value "Message consumed report requested". That SDS-TL message reference value may be numerically less than some other SDS-TL message reference value in a concatenated message.

- If the whole concatenated message is not received, then it shall not send a consumption report, refer to clause 29.5.14.8.2.

Upon receiving a concatenation-part with Delivery report request with value "No delivery report requested" the receiving concatenation entity acts:

- if the whole concatenated message is not received, then the receiving concatenation entity shall not send any report to that concatenation part to the sending concatenation entity;
- if the whole concatenated message is received and passed to the upper layers then receiving concatenation entity shall not send any report to the sending concatenation entity;
- if an error is detected in an individually addressed concatenation part or in the whole concatenated message, then a SDS-REPORT PDU shall be sent to the sending concatenation entity. If an error occurs when receiving a broadcast or group addressed message, the MS shall not send an SDS-REPORT PDU to the sending party the message shall be silently discarded.

NOTE 3: The present document does not define how the receiving entity could request retransmission of a specific concatenation-part, refer to clause 29.5.14.8.5.

#### 29.5.14.8.4 Acknowledgements of SDS-REPORT PDUs

The concatenation layer should not normally ask request acknowledgements to the individual SDS-REPORT PDUs. For the whole concatenated message a higher layer application may request acknowledgement in a Concatenation-REPORT request. The concatenation layer may ask request the acknowledgement in the last concatenation-part of a concatenated message. The higher layer application will then use Concatenation-ACK request primitive with concatenation reference and the concatenation layer shall send SDS-ACK PDU with the corresponding Message reference, refer to clause 29.3.3.5. It is recommended that user application asks acknowledgement to a Concatenation-REPORT request only in direct transport without a forwarding entity.

NOTE: As the Concatenation layer uses SDS-TL service SDS-ACK PDU the acknowledgements are between SDS-TL aware nodes and are end to end only, when no forwarding service is used, refer to clause 29.3.3.1.

If SwMI or a forwarding entity asks requests acknowledgements in SDS-REPORT PDUs, then the concatenation layer shall send SDS-ACK PDUs to those and shall not inform service user about the requests.

#### 29.5.14.8.5 Exceptional conditions

While sending a concatenated message the sending entity may receive an SDS-REPORT PDU with a Delivery status value "Concatenated message too long" as a response for a SDS-TRANSFER PDU independently whether one or more or all concatenation parts have been sent and the sending entity shall stop sending the corresponding concatenated message and pass the failure indication to the upper layer application in a Concatenation-REPORT indication. Receiver does not continue to receive the message.

The receiving concatenation entity may apply a timeout between receptions of concatenation-parts. The same timeout may be applied also, when the last concatenation part is received, but one or more concatenation-part is not received. At the timeout the receiving concatenation entity may send an SDS-REPORT PDU with "Concatenation entity has not received some of the concatenation parts, message discarded". Receiver does not continue to receive the message. How the sending entity may use this information and the timeout value is outside the scope of the present document.

#### 29.5.14.9 Concatenation management

An upper layer application may want to control parameters of concatenation by using a Concatenation-MANAGEMENT request primitive. The concatenation entity may inform recommended concatenation parameters to the upper layer application using a Concatenation-MANAGEMENT indication primitive.

The Concatenation-MANAGEMENT request primitive is used before a Concatenation-TRANSFER request primitive and will define how the concatenated message should be sent. MS may also apply some default values, if a Concatenation-MANAGEMENT request is not used to set the transfer parameters. The default values are outside the scope of the present document.

MS may provide a Concatenation-MANAGEMENT indication primitive to inform user application about the concatenation parameters.

#### 29.5.14.10 Timestamp usage

If a timestamp is used as defined in clause 29.3.2.9, then SwMI will add it only to the concatenation part that contains the payload PID. So if SwMI adds a timestamp, then it identifies the approximate time of the start of the sending of the concatenated message.

### 29.5.14.11 Concatenation coding requirements

#### 29.5.14.11.1 Concatenation control

The concatenation control information elements shall be coded as presented in table 29.60.

**Table 29.60: Concatenation control information elements for concatenation transfer contents**

| Information element   | Length | Type | C/O/M | Value    | Remark  |
|---|--------|------|-------|----------|---|
| Concatenation control PDU type  | 3      | 1    | M     |          | Concatenation transfer                        |
| Concatenation reference type  | 1      | 1    | M     | 0        | Concatenation reference extension not present |
|   |        |      |       | 1        | Concatenation reference extension present     |
| Concatenation reference extension   | 8      |      | C     |          | See notes 1 and 2                             |
| Short concatenation reference   | 4      | 1    | M     |          | See note 2                                    |
| Number of concatenation-parts   | 8      | 1    | M     | 2 to 255 |   |
| Sequence number of the current concatenation-part   | 8      | 1    | M     | 1 to 255 |   |
| NOTE 1: This information element shall be present as indicated by the concatenation reference type.   |        |      |       |          |   |
| NOTE 2: When the Concatenation reference extension information element is present, then it shall contain the most significant bits of the concatenation reference and the Short concatenation reference information element shall contain the least significant bits of the 12 bits long concatenation reference value. |        |      |       |          |   |

#### 29.5.14.11.2 Concatenation control PDU type

The concatenation control PDU type information elements shall be coded as presented in table 29.61.

**Table 29.61: Concatenation control PDU type contents**

| Information element            | Length | Value            | Remark                 |
|--------------------------------|--------|------------------|------------------------|
| Concatenation control PDU type | 3      | 000 <sub>2</sub> | Concatenation transfer |
|                                |        | 001 <sub>2</sub> | Reserved               |
|                                |        | etc.             | etc.                   |
|                                |        | 111 <sub>2</sub> | Reserved               |

### 29.5.14.12 Concatenation message examples

#### 29.5.14.12.1 Concatenation of SDS messages without SDS-TL data transport service

When SDS-TL data transfer service is not used the PID that defines a concatenated SDS shall be followed by concatenation control information element, refer to clause 29.5.14.5.

The format of SDS-TL message without SDS-TL data transport service shall be as defined in table 29.62.

**Table 29.62: Concatenation-part message without SDS-TL data transfer service**

| Information element   | Length   | Type | C/O/M | Remark   |
|---|----------|------|-------|--|
| Protocol identifier   | 8        | 1    | M     | Concatenated SDS without SDS-TL data transport service |
| Concatenation control   | variable | 1    | M     | Refer to table 29.60                                   |
| PID of the user payload message   | 8        |      | C     | See notes 1 and 2                                      |
| User data   | variable | 1    | M     |  |
| NOTE 1: That information element shall be present only when the Sequence number of current concatenation-part information element value is "1". |          |      |       |  |
| NOTE 2: The PID of the user data payload message can be any other than a concatenation indication PID of the table 29.21.                       |          |      |       |  |

### 29.5.14.12.2 Concatenation of SDS messages with SDS-TL data transport service

When SDS-TL data transfer service is used the set of concatenation control information elements shall be after the SDS-TL data transfer service information elements, refer to clause 29.5.14.5 and table 29.63.

Although the PID of the user data can indicate that SDS-TL data transfer service shall be used, refer to note 5 in table 29.21, the Protocol identifier of the concatenated SDS in the first information element shall define whether the SDS-TL data transfer service is used or not and there shall be no SDS-TL data transfer service related information elements after the PID of the user payload message information element.

**Table 29.63: Concatenation-part message with SDS-TL data transfer service**

| Information element   | Length   | Type | C/O/M | Remark   |
|---|----------|------|-------|--|
| Protocol identifier   | 8        | 1    | M     | Concatenated SDS with SDS-TL data transfer service |
| Message type  | 4        | 1    | M     | SDS-TRANSFER                                       |
| Delivery report request   | 2        | 1    | M     |  |
| Service selection/Short form report   | 1        | 1    | M     |  |
| Storage/forward control   | 1        | 1    | M     |  |
| Message reference   | 8        | 1    | M     | Refer to table 29.14                               |
| Validity period   | 5        |      | C     | Refer to table 29.14                               |
| Forward address type  | 3        |      | C     | Refer to table 29.14                               |
| Forward address short number address  | 8        |      | C     | Refer to table 29.14                               |
| Forward address SSI   | 24       |      | C     | Refer to table 29.14                               |
| Forward address extension   | 24       |      | C     | Refer to table 29.14                               |
| Number of external subscriber number digits   | 8        |      | C     | Refer to table 29.14                               |
| External subscriber number digit  | 4        |      | C     | Refer to table 29.14                               |
| Dummy digit   | 4        |      | C     | Refer to table 29.14                               |
| Concatenation control   | variable | 1    | M     | Refer to table 29.60, note 1                       |
| PID of the user payload message   | 8        | 1    | M     | See notes 1, 2 and 3                               |
| User data   | variable | 1    | M     |  |
| NOTE 1: SDS-TL shall consider these information elements to be a part of User data.   |          |      |       |  |
| NOTE 2: That information element shall be present only when the Sequence number of current concatenation-part information element value is "1". |          |      |       |  |
| NOTE 3: The PID of the user data payload message can be any other than a concatenation indication PID of the table 29.21.                       |          |      |       |  |

## 29.5.15 Simple AGNSS

### 29.5.15.1 General

The Simple AGNSS protocol is intended to be a very basic AGNSS application, which does not require any transport mechanism to ensure delivery.

### 29.5.15.2 Protocol sequences

Simple AGNSS does not use any end-to-end acknowledgement (reporting) signaling. The only delivery mechanisms offered is the layer 2 acknowledge.

### 29.5.15.3 PDU description tables

Simple AGNSS does not use the SDS-TL data transfer service PDUs, but defines a protocol specific field to specify the data format, refer to clauses 29.5.16.5 and 29.5.16.6. The basic SDS type-4 information element shall contain elements as defined in clause 29.5.15.4.

### 29.5.15.4 Simple AGNSS unitdata

Response to: -

Response expected: -

Short description: This PDU shall be used to send AGNSS SDS data

**Table 29.64: Simple AGNSS PDU contents**

| Information element | Length   | Type | C/O/M | Remark                           |
|---------------------|----------|------|-------|----------------------------------|
| Protocol identifier | 8        | 1    | M     | "00001110"<br>(decimal value 14) |
| AGNSS constellation | 4        | 1    | M     | As defined in table 29.66        |
| AGNSS coding scheme | 4        | 1    | M     | As defined in table 29.67        |
| AGNSS data          | Variable | 1    | M     |                                  |

## 29.5.16 AGNSS using SDS-TL data transfer services

### 29.5.16.1 General

This AGNSS protocol set offers end-to-end acknowledgement and/or store and forward in the SwMI.

### 29.5.16.2 Protocol sequences

The protocol sequences of AGNSS messaging shall be the protocol sequences defined in clause 29.3.3.

### 29.5.16.3 PDU description tables

The AGNSS protocol uses the full TL protocol. Additional information elements are present in the SDS-TRANSFER PDU.

### 29.5.16.4 AGNSS transfer SDU

The AGNSS transfer is done by use of an SDS-TRANSFER with additional information elements embedded in the user data portion of the SDS-TRANSFER. The AGNSS SDU shall be encoded as defined in table 29.65.

**Table 29.65: AGNSS SDU contents**

| Information element | Length   | Type | C/O/M | Remark                    |
|---------------------|----------|------|-------|---------------------------|
| AGNSS constellation | 4        | 1    | M     | As defined in table 29.66 |
| AGNSS coding scheme | 4        | 1    | M     | As defined in table 29.67 |
| AGNSS data          | Variable | 1    | M     |                           |

### 29.5.16.5 AGNSS constellation

For protocols carrying AGNSS data, the 'AGNSS constellation' information element shall be as defined in table 29.66.

**Table 29.66: AGNSS constellation information element contents**

| Information element  | Length | Value        | Remark  |
|--|--------|--------------|---|
| AGNSS constellation  | 4      | 0000 to 1111 | 0000: GPS<br>0001: GALILEO<br>0010: GLONASS<br>0011: BEIDOU<br>0100: WAAS<br>0101: EGNOS<br>0110: MSAS<br>0111: IRNSS<br>1000: QZSS<br>1001 to 1111: available to future constellations |
| NOTE: Identities of these applications should be allocated by a central body in order to support interoperability. |        |              |   |

NOTE: The AGNSS Constellation Identifier is coded over 4 bits as NAP2 is specified to support 16 constellations.

### 29.5.16.6 AGNSS coding scheme

For protocols carrying AGNSS data, the 'AGNSS coding scheme' information element shall be as defined in table 29.67.

**Table 29.67: AGNSS coding scheme information element contents**

| Information element  | Length | Value        | Remark  |
|--|--------|--------------|---|
| AGNSS coding scheme  | 4      | 0000 to 1111 | 0000 : TETRA NET ASSIST Protocol 2, NAP2 ETSI TS 100 392-18-4 [49]<br>0001 to 1111: available to future coding schemes. |
| NOTE: Identities of these applications should be allocated by a central body in order to support interoperability. |        |              |   |

NOTE: This list only defines a subset of the available data coding schemes for AGNSS. The list should be expected to expand as more data coding schemes are adopted.

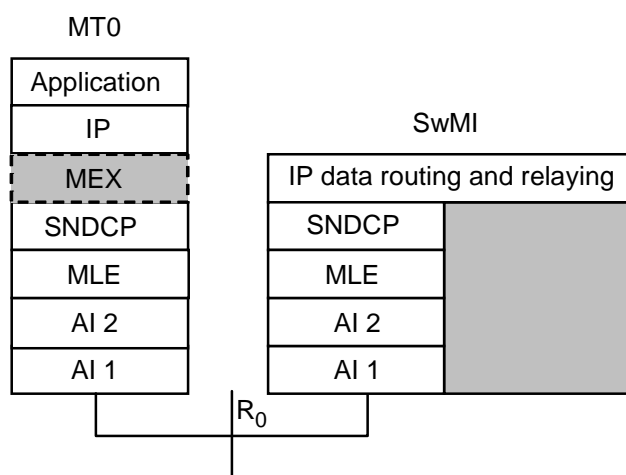

## 30 Multimedia Exchange Layer

### 30.1 General

Clause 30 describes the structure and the functionality of the TETRA Multimedia Exchange (MEX) Layer. The TETRA MEX layer resides above the SNDCP defined in clause 28.

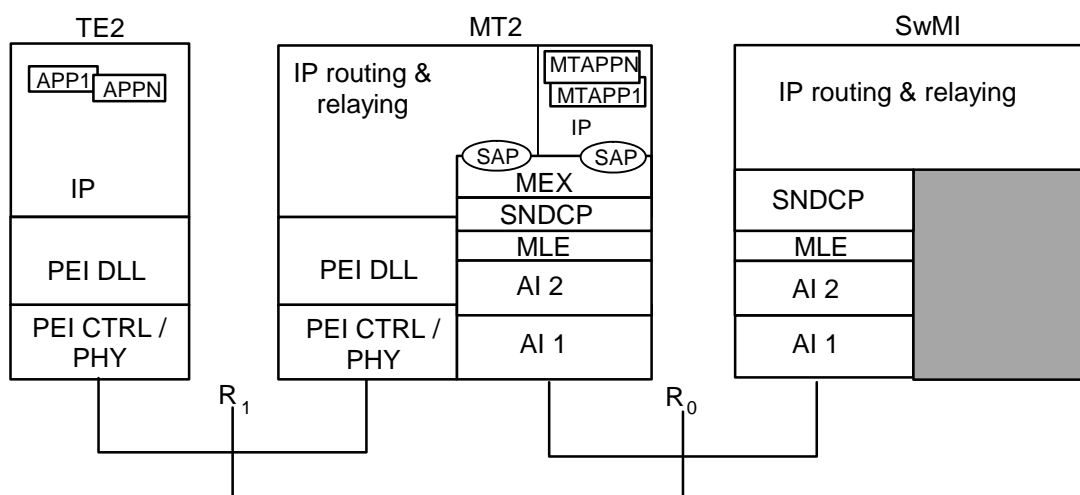

The MEX layer supports the Internet Protocol (IP) and at the MS side the IP and the higher layers on top of it may be located at the MT and the TE. Support of the full MEX layer functionality is optional.

Figure 30.1 illustrates the usage of TETRA MEX layer with the applications in MT.

**Figure 30.1: Usage of TETRA packet data with MEX Layer with an MT0 application**

Figure 30.2 illustrates the usage of TETRA packet data with the MEX layer when the application uses IP protocol. Applications are illustrated with co-existence within both the TE2 and MT2 allowing them to independently access TETRA packet data services and associated QoS management.

**Figure 30.2: Usage of TETRA packet data with MEX for TE2 and MT2 IP applications**

The IP traffic from the TE and MT applications go through the MEX layer. The MEX layer handles three types of IP traffic:

Type 1 - Control traffic between the applications and the MEX layer.

Type 2 - Data traffic between the applications and the SNDCP layer via the MEX layer.

Type 3 - Data traffic between the applications and the SNDCP layer (bypassing the MEX layer).

In addition, the MEX layer handles the communication with the SNDCP layer using the SNDCP primitives, which will be discussed as part of this clause in the later sections. First, the details of the MEX layer interface will be described.

Figure 30.3 illustrates a typical deployment example showing the full set of components involved, namely:

- PEI Ctrl/Phy - The peripheral equipment interface.
- PCON - A logical connection associated with the PEI physical connection. Where a modern high speed connectivity technology is implemented, several logical PCONs may be available. In a legacy implementation only one PCON is available utilizing a V.24/V.28 physical interface.
- DLL (PEI) - The link layer protocol for carrying data across the Peripheral Equipment Interface (PEI). Most commonly, Point to point protocol (PPP) is employed.
- NCON - A network connection consisting of an IP address, Subnet mask, Gateway address and other applicable parameters for support of carrying IP packets to and from the MT2. Where multiple PDP contexts are supported, both the TE2 and internal application environment of the MT2 can host multiple NCONs and hence, multiple IP addresses. An NCON can typically be a connected PPP connection over a PCON.
- IP - The section of the IP stack related to an applicable NCON.
- Applications - Applications requiring both uplink and downlink packet data services.
- QoS Manager - An agent which often resides close to the IP stack which can negotiate QoS services and capabilities in IP networks. In TETRA, the QoS Manager may use either AT commands or TNPI protocol to negotiate QoS enabled packet data services. Applications, themselves, may also implement QoS management functionality.

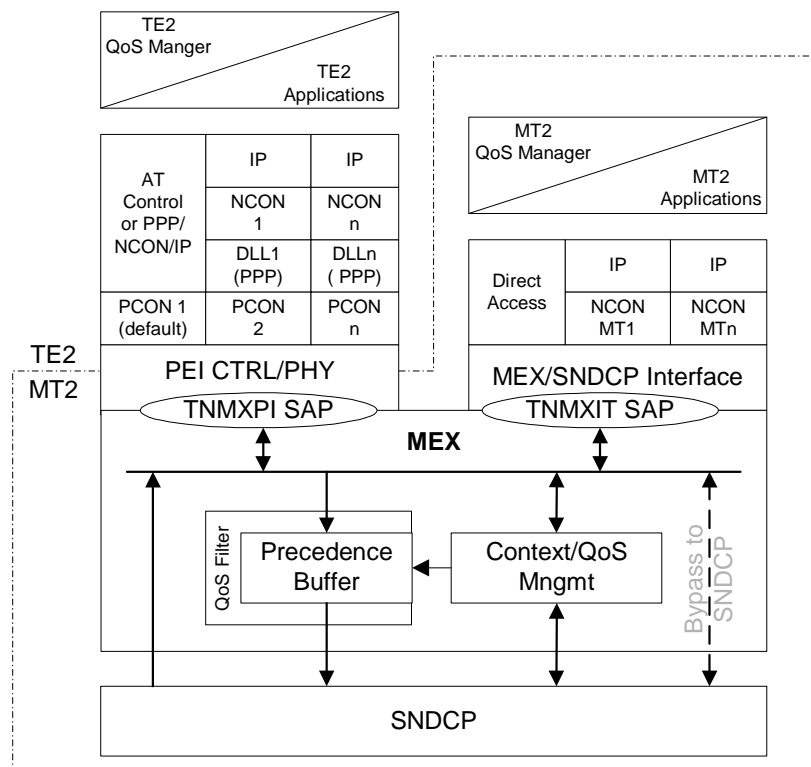

Figure 30.3: MEX Peripheral Interfaces

Access to MEX services is available via 2 possible SAPs:

- TNMXPI SAP - Service Access Point to carry data and configuration via the Peripheral Equipment Interface (PEI). For clarity, the PEI section of Figure 30.3 illustrates multiple logical PEI connections (PCON) over which applications may communicate through TNMXPI. Note that applications may have either a dedicated PCON or may share a PCON (PCON<sub>n</sub>). Furthermore, these relations, by definition, bear no specific mapping to a particular PDP context at the SNDCP.
- TNMXIT\_SAP - Service Access Point to carry data and configuration related to applications housed internally to the MT.

The MEX layer incorporates the following functionality some of which is mandatory or optional as denoted by (M) or (O):

- QoS Filter (M) - To assist in routing of application data having different QoS requirements to appropriately predefined PDP contexts.
- Precedence Buffer (O) - To manage flow of IP packets to SNDCP according to precedence requirements.
- Context/QoS Management (M)- To provide an abstracted interface to PDP context creation and modification, QoS negotiation and Uplink data routing via the QoS Filter.

Each application using the MEX layer transfers data through the IP transport layers via NCONs. The application or associated QoS Manager on the MS may, if MEX is supported, request its QoS via the MEX-CONNECT primitive together with the QoS filter information. Upon success, a PDP context exists and the MEX and SwMI are prepared to route data with the appropriate QoS on both the uplink and downlink.

MEX supports three forms of QoS filtering:

- 1) Port Filtering - The MEX inspects the destination port and protocol (port type) fields of the uplink IP transport packet header and ensures that the packet is routed via SNDCP SN-DATA primitive to the NSAPI with the previously accepted QoS. The use of a port filter requires that the application is using a port oriented transport protocol (e.g. UDP, TCP, SCTP and DCCP).
- 2) Port and Peer IP Address Filtering - The destination IP Address is inspected in addition to the destination port and protocol fields of the uplink IP transport packet header and ensures that the packet is routed via SNDCP SN-DATA primitive to the NSAPI with the previously accepted QoS. This method allows differentiation of QoS for similar applications residing on different peer nodes in the packet network.
- 3) Diffserv - The lower 5 bits (4 to 0) of the 6 bit Differentiated services Code Point (DSCP) is inspected in the IP packet header and ensures that the packet is routed via SNDCP SN-DATA primitive to the NSAPI with the previously accepted QoS. The application should appropriately utilize the "Per Hop Behaviour (PHB)" classes which are defined by IETF RFC 2474 [43], IETF RFC 2475 [44], IETF RFC 2597 [45] and IETF RFC 3246 [46]. Bit 5 of DSCP is used to allow the application to utilize the escalated priority functionality which is defined within the MEX.

MEX itself can perform QoS filtering only on the uplink. However, interfaces are provided to allow requests to be forwarded via SNDCP in order to set QoS filtering at the SwMI to facilitate filtering on the downlink also.

Four QoS filter transaction types are defined:

- 1) Uplink Filter - The application on the MS sends IP packets to a peer on the IP network. IP packets are routed to a PDP context on the Uplink by the MEX QoS filter based upon either:
  - the destination port and protocol field;
  - destination port and protocol field plus destination IP address; or
  - DSCP of the transmitted IP transport packets.

- 2) Downlink Filter - The application on the MS awaits receipt of IP packets on the downlink from the IP network. Downlink IP transport packets may be routed to a PDP context at the SwMI based upon either:
- the destination port and protocol field;
  - destination port and protocol field plus source IP address; or
  - DSCP of the IP packet.
- 3) Downlink Automatic Filter - The application on the MS sends IP packets to a peer on the IP network. Uplink IP packets are routed to a PDP context on the uplink by the MEX QoS Filter based upon either:
- destination port and protocol field;
  - destination port and protocol field plus destination IP address; or
  - DSCP of the IP packet.

Either the:

- source port and protocol field;
- source port and protocol field plus destination IP; or
- DSCP of the uplink IP packet;

may be recorded at the SwMI to allow for automatic downlink filtering. Automatic filtering at the SwMI on the downlink may use the recorded information to filter downlink packets by either:

- destination port and protocol field;
- destination port and protocol field plus source IP address; or
- DSCP to the appropriate PDP context.

- 4) Uplink Automatic Filter - The application on the MS awaits receipt of IP transport packets on the downlink from the IP network. Downlink IP transport packets are routed to PDP context at the SwMI based upon either:
- destination port and protocol field;
  - destination port and protocol field plus source address; or
  - DSCP of the IP packet.

Either the:

- source port and protocol field;
- source port and protocol field plus source IP address; or
- DSCP of the downlink IP packet;

is recorded at the MEX QoS Filter to allow for automatic uplink filtering. Automatic filtering at the MEX QoS Filter uses recorded information to filter uplink packets by:

- destination port and protocol field;
- destination port and protocol field plus destination IP address; or
- DSCP.

Automatic filters are defined to support the client/server connection oriented nature of the IP protocol.

Where multiple filters are specified, there may be the occasion where an Uplink or Downlink Filter may conflict with a filter automatically determined by an automatic filter. In this state, the explicitly defined Uplink or Downlink filter shall take precedence and override that automatically defined filter.

The usage of DSCP is outside the scope of the present document.

The method of transferring peer IP address or Diffserv QoS Filter information to the SwMI for the purpose of downlink filtering is outside the scope of the present document. Therefore QoS Filtering including the peer IP address or Diffserv may be only supported on the uplink.

## 30.2 MEX Layer Overview

### 30.2.1 General

MEX is a TETRA specific network layer with the primary objective to provide a simplified interface to allow the development of applications which can take advantage of the advanced QoS capabilities made available by the packet data service of TETRA.

MEX can offer 3 levels of abstraction to the application or QoS Manager with respect to the negotiation of QoS:

- 1) Legacy context - An application initiates a packet data transfer (equivalent to ATD\*99#). The MEX initiates creation of a PDP context via SMDCP using a default set of QoS settings (see clause 3.2.2.4; MEX QoS Class entry 0).
- 2) MEX QoS - An application or QoS Manager initiates creation of a PDP context by specifying a range of QoS by specifying 2 of 256 QoS abstract classes; one indicating an upper QoS requirement and one indicating a lower QoS requirement and a QoS filter specification. The MEX then automates the creation of the PDP context, and negotiates the QoS within the specified limits. The full range of QoS classes and attributes together with MEX QoS filtering on the uplink is available in this mode.
- 3) SMDCP QoS - An application or QoS Manager may initiate direct creation of a PDP context and data transfer using the full SMDCP QoS primitives. Automatic negotiation using MEX QoS class, MEX Precedence, MEX QoS filtering on the uplink are not supported in this mode.

NOTE: SMDCP QoS is negotiated between SwMI and MS or the default background class QoS is applied (see clause 28.3.4.8).

Applications residing on both TE2 and MT2 the can utilize any of the three options above and can coexist at any time, limited only by the services available at the SMDCP.

### 30.2.2 QoS Classes

#### 30.2.2.1 Data Class

Each TE2 and MT2 application that requires access to the MEX layer can belong to one of three classes. MEX layer offers QoS to the following multimedia service classes:

- |                  |   |
|------------------|---|
| Real-time class  | layer 2 link optimized for data which cannot tolerate delivery delay (late packets discarded by the receiving application); |
| Telemetry class  | layer 2 link optimized for intermittent data which can tolerate moderate delivery delay and packet loss;                    |
| Background class | layer 2 link optimized for data which are intolerant of packet loss.  |

Real-time class applications require regular access to the radio resources, and have low delay tolerance. Although data reliability is important for such applications, it can be compromised for low transmission delays. Typical examples of applications which would utilize this class are video conferencing and packet speech transmission.

The telemetry class applications may also require regular access to the radio resources, and have moderate delay tolerance (higher than real-time class). Reliability can be compromised for short transmission delays. Depending on the update rate of the application data, even unacknowledged transmission may be used. Typical examples include location update, medical telemetry and data logging applications.

The background class is the most delay tolerant among all the multimedia classes. In most cases, the objective is to transmit the packets correctly despite long delays. Although high data throughput is a desirable feature, its absence does not dramatically affect the usability of the application. Web browsing, file transmission and control applications belong to this class.

If QoS is not negotiated, then the background class is provided as default (see clause 28.3.4.8).

### 30.2.2.2 Delay Class

Maximum packet delay refers to the delay within a single SwMI TETRA network from MS to MS.

The reader should refer to clause 28.2.3.2 for details of achievable maximum packets delays for each of the delay Classes:

- Low;
- Moderate;
- High; and
- Unpredictable.

### 30.2.2.3 Reliability Class

Packet reliability is specified for the local MS - SwMI air interface for a single link and it is not associated with the end-to-end reliability.

The reader should refer to clause 28.2.3.2 for details of N-PDU reliability for each of the reliability classes:

- High;
- Moderate; and
- Low.

### 30.2.2.4 MEX QoS abstract class

The MEX QoS Abstract class is defined for the ease of setting the multitude of QoS parameters by the application. The MEX shall implement a table (MEX\_QOS\_CLASS\_TBL) of up to 256 MEX QoS abstract classes which can be chosen or modified by the TE2 application via MEX-QOSCLASS. A default QoS class 0 is used to support legacy applications which do not request any QoS via the PEI. MEX QoS Classes 0-8 are defined in this specification and shall be implemented in all MT2. These are shown in table 30.3 MEX QoS Classes 9 to 32 are reserved for addition of manufacturer specific values. For entries in MEX\_QOS\_CLASS\_TBL which are accessible for modification (33 to 255), a lock feature is available to prevent applications from modifying each others' entries in the MEX\_QOS\_CLASS\_TBL.

Two entries in the MEX QoS Class table can be used to define a range of acceptable QoS during MEX-CONNECT to allow MEX the flexibility to automatically negotiate QoS with SndCP and, hence, the network. Where a range (Upper and Lower) is used the following table 30.2 clarifies the upper and lower values for each QoS Class / Parameter.

**Table 30.1: Void**

**Table 30.2: Full Range of operation for QoS Classes and Attributes**

| <b>Class / Attribute</b>             | <b>Upper</b> | <b>Lower</b>  | <b>Note</b>  |
|--------------------------------------|--------------|---------------|--|
| Minimum Peak Throughput              | ≥ 64 000     | < 1 000       | Octets/s   |
| Mean Throughput                      | Best effort  | 100           | Octets/h   |
| Mean Active Throughput               | Best effort  | 100           | Octets/h   |
| Data Class                           | Real time    | Background    |  |
| Delay Class                          | High         | Unpredictable |  |
| Reliability Class                    | High         | Low           |  |
| CONTEXT_READY time                   | 300 s        | 200 ms        | Where track READY timer is required, this should be entered for both upper and lower |
| Scheduled Repetition Period          | 706          | 4             | Slot durations (85/6 ms)   |
| Scheduled Timing Error               | 1            | 128           | Slot durations (85/6 ms)   |
| Scheduled Number of N-PDUs per grant | 7            | 1             |  |
| Scheduled N-PDU size                 | 2 002        | 1             | Octets   |
| MEX Precedence                       | 14           | 1             |  |
| MEX Data Priority                    | 7            | 0             |  |
| MEX PDU Priority Max                 | 7            | 0             |  |
| MEX Data Importance                  | High         | Low           |  |

Applications which do not have a preference for a particular class or parameter should specify the extreme range as given in the table 30.3. Applications which have a direct need should specify the specific range as tightly as appropriate for the specific requirement or specify identical values in both the upper and lower request.

Table 30.3: Fixed values for MEX QoS Class

| QoS parameter                        | MEX QoS class             |                           |                           |           |           |            |               |               |               | Remarks                            |
|--------------------------------------|---------------------------|---------------------------|---------------------------|-----------|-----------|------------|---------------|---------------|---------------|------------------------------------|
|                                      | 0 (default)               | 1                         | 2                         | 3         | 4         | 5          | 6             | 7             | 8             |                                    |
| Minimum peak throughput              | < 1 000                   | < 1 000                   | < 1 000                   | ≥ 1 000   | ≥ 2 000   | ≥ 4 000    | ≥ 1 000       | ≥ 8 000       | ≥ 32 000      | Octets/s                           |
| Mean throughput                      | Best effort               | 100 000                   | 10 000                    | 500 000   | 2 000 000 | 10 000 000 | Best effort   | Best effort   | Best effort   | Octets/h                           |
| Mean active throughput               | < 1 000                   | < 1 000                   | < 1 000                   | ≥ 1 000   | ≥ 2 000   | ≥ 4 000    | 50 000 000    | 50 000 000    | 50 000 000    | Octets/h                           |
| Data class                           | Background                | Background                | Background                | Telemetry | Telemetry | Telemetry  | Real time     | Real time     | Real time     |                                    |
| Delay class                          | Unpredictable             | Unpredictable             | Unpredictable             | Low       | Moderate  | High       | Low (default) | Low (default) | Low (default) | Unpredictable, High, Moderate, Low |
| Reliability class                    | Moderate                  | Moderate                  | High                      | High      | Moderate  | Low        | Low (default) | Low (default) | Low (default) | High, Moderate, Low                |
| CONTEXT_READY time                   | track READY               | track READY               | track READY               | 500 ms    | 1 s       | 2 s        | 3 s           | 2 s           | 500 ms        |                                    |
| Schedule repetition time             | N/A<br>(Background class) | N/A<br>(Background class) | N/A<br>(Background class) | 20        | 50        | 70         | 150           | 100           | 20            | 4 to 706 slot durations (85/6 ms)  |
| Schedule timing error                | N/A<br>(Background class) | N/A<br>(Background class) | N/A<br>(Background class) | 2         | 5         | 10         | 3             | 2             | 1             | ≤ 1 to ≤ 128 slot durations        |
| Scheduled number of N-PDUs per grant | N/A<br>(Background class) | N/A<br>(Background class) | N/A<br>(Background class) | 1         | 1         | 1          | 5             | 6             | 7             | 1 to 7 N-PDUs per grant            |
| Scheduled N-PDU size                 | N/A<br>(Background class) | N/A<br>(Background class) | N/A<br>(Background class) | 150       | 500       | 1 000      | 500           | 2 000         | 1 300         | Octets                             |
| MEX precedence                       | 1                         | 1                         | 1                         | 2         | 2         | 2          | 10            | 12            | 14            | 1 to 14                            |
| MEX data priority                    | 0                         | 0                         | 0                         | 6         | 4         | 0          | 6             | 4             | 0             | 0 - Low, 7 - High                  |
| MEX PDU priority max                 | 0                         | 0                         | 0                         | 6         | 4         | 0          | 6             | 4             | 0             | 0 - Low, 7 - High                  |
| MEX data importance                  | High                      | Medium                    | Low                       | High      | Medium    | Low        | High          | Medium        | Low           | Low, Medium, High                  |

## 30.2.3 QoS Attributes

### 30.2.3.1 General

In addition to the QoS classes described above, the MEX layer supports the following QoS attributes which shall be as defined in the clauses 30.2.3.2 to 30.2.3:

- Data throughput;
- MEX precedence;
- Data Priority;
- PDU Priority;
- Data importance;
- Scheduled access; and
- CONTEXT\_READY time.

### 30.2.3.2 Data Throughput

An MT or TE application always requests the following parameters as different throughput measures:

- **Minimum Peak Throughput:** The expected minimum peak throughput, measured in octets per second. This indicates to the lower layers how allocate channel bandwidth, coding and modulation in order to achieve the minimum peak throughput require by the application. This is the minimum peak throughput of N-PDUs in units of octets per second requested or offered for a particular PDP context. This is the minimum throughput required when the PDP context is at its most active; if the peak rate available is lower than this, the application may not be usable (though the application may be capable of using a higher rate than this). Valid values are:
  - < 1 000;
  - $\geq 1\ 000$ ;
  - $\geq 2\ 000$ ;
  - $\geq 4\ 000$ ;
  - $\geq 8\ 000$ ;
  - $\geq 16\ 000$ ;
  - $\geq 32\ 000$ ; and
  - $\geq 64\ 000$ .
- **Mean Throughput:** The expected mean throughput, measured in octets per hour is averaged over the expected lifetime of the associated PDP context. This is the mean throughput of N-PDUs expected by the SNDSCP service user, averaged over the expected lifetime of the PDP context. It is given in units of octets per hour. Valid values are:
  - 100 (~0,22 bits/s);
  - 200 (~0,44 bits/s);
  - 500 (~1,11 bits/s);
  - 1 000 (~2,2 bits/s);
  - 2 000 (~4,4 bits/s);
  - 5 000 (~11,1 bits/s);

- 10 000 (~22 bits/s);
- 20 000 (~44 bits/s);
- 50 000 (~111 bits/s);
- 100 000 (~0,22 kbits/s);
- 200 000 (~0,44 kbits/s);
- 500 000 (~1,11 kbits/s);
- 1 000 000 (~2,2 kbits/s);
- 2 000 000 (~4,4 kbits/s);
- 5 000 000 (~11,1 kbits/s);
- 10 000 000 (~22 kbits/s);
- 20 000 000 (~44 kbits/s);
- 50 000 000 (~111 kbits/s); and
- Best effort.

NOTE: These values follow those given for GPRS (see ETSI EN 301 344 [i.11]).

- **Mean Active Throughput:** The mean active throughput, measured in octets per hours, is averaged over the period defined by the CONTEXT\_READY time. Values shall be as for the Mean throughput.

### 30.2.3.3 MEX Precedence

MEX precedence defines how frequently application data is transferred to the SNDSCP for transmission, which is achieved by a queuing mechanism at the MEX layer. The MEX layer provides data precedence internally, which can manage an unlimited number of applications simultaneously. Each application can choose one of 14 precedence levels (1 to 14). Note that if an application does not specify a precedence level, it is assigned to precedence level 1.

The MEX precedence mechanism consists of an application list, multiple buffers and a precedence switch as shown in figure 30.4. MEX Precedence is a round robin mechanism which processes and transfers packets to the SNDSCP as follows:

- up to 14 packets from each application which has specified precedence level 14;
- up to 13 packets from each application which has specified precedence level 13;
- and so on for each precedence level; until
- one packet is processed for each application which has requested precedence level 1.

The round robin then continues again at precedence level 14.

During PDP context activation, the application chooses the MEX precedence level using MEX-CONNECT, and the MEX layer places that application to its precedence list. Each precedence level is associated with an internal buffer. Therefore, after an application chooses its MEX precedence, its MEX-DATA payload is routed to a corresponding buffer. Each buffer output is connected to a precedence switch, which allocates the available MEX output bandwidth dynamically. In other words, high precedence data is transferred more frequently than the low precedence one.

A precedence rank figure is defined to allow an application to understand its real placement within the precedence buffer where there may be other application operating for which the requesting application is not directly aware. Equation 1 describes how precedence rank is derived. This provides a figure relating to the ratio of full precedence bandwidth that the application is actually given. An application may then choose to modify its MEX Precedence or other QoS parameter should its actual placement not be sufficient.

$$PR = \frac{RP}{\sum_{n=1}^{14} n * NAP} \quad (30.1)$$

where:

PR = Precedence Rank.

RP = Requested Precedence level.

NAP = Number of applications which are operational at that precedence.

If the MEX precedence functionality is not supported, Precedence Rank will always equal 0.

Two examples of usage are given in order to explain the functionality offered by the MEX precedence buffer.

**EXAMPLE 1:** In simple terms, application A requests precedence 14 and application B requests precedence 7. Where both applications provide a sensible matched throughput to the requested MEX precedence, the precedence switch transfers 14 packets (MEX-DATA primitives) as SN-DATA to the SNDPCP. Once 14 packets of application A are transferred, 7 packets of application B are then transferred. Application A therefore has twice the precedence of application B. A similar precedence is achieved using precedence 2 and 1 respectively effectively operating in a different precedence dimension. However, the application may wish to request an appropriate precedence dimension to assist in matching an equivalent Scheduled access (i.e. Scheduled N-PDUs per grant).

Precedence Rank for both cases is therefore:

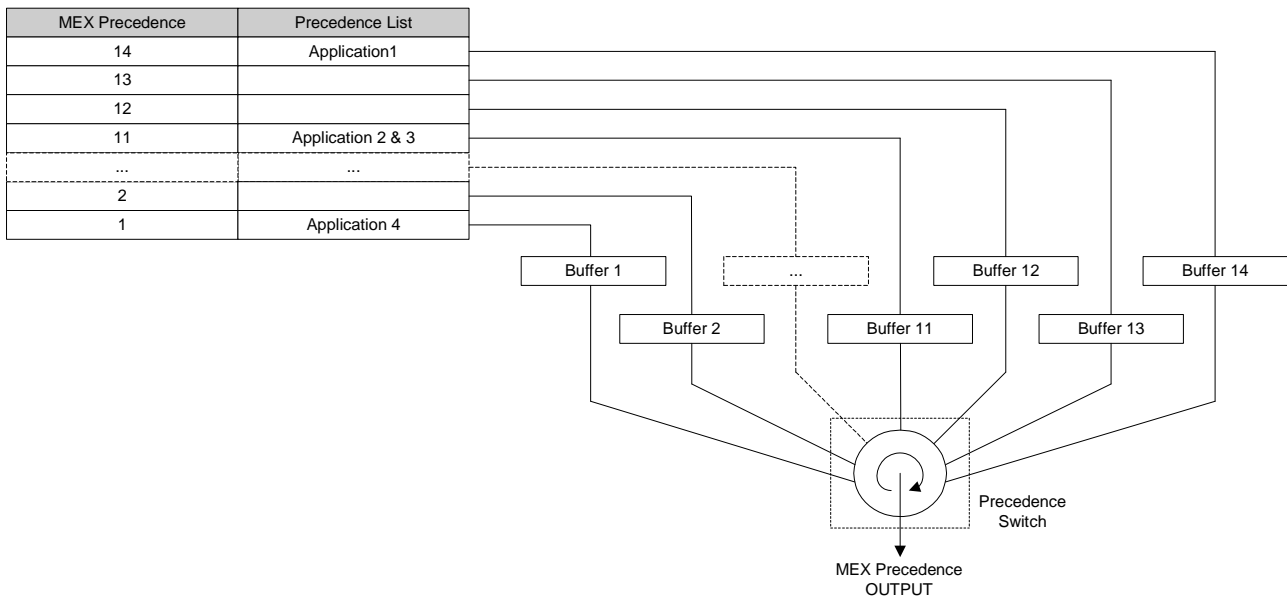

- Application A - 0,667 (66,7 %);
- Application B - 0,333 (33,3 %).

**EXAMPLE 2:** Figure 30.4 illustrates 4 applications populating the precedence list. Where all applications provide a sensible matched throughput to the requested MEX precedence, the follow packet transfer occurs:

- 14 packets of application 1;
- 11 packets of application 2;
- 11 packets of application 3; and
- 1 packet of application 4.

Precedence Rank is therefore:

- Application 1 has PR=0,378 (37,8 %);
- Application 2 has PR=0,297 (29,7 %);
- Application 3 has PR=0,297 (29,7 %); and
- Application 4 has PR=0,027 (2,7 %).

**Figure 30.4: MEX Precedence**

#### 30.2.3.4 Data Priority

Data priority allows an MS to transmit high data-priority N-PDUs (IP packets) ahead of lower data-priority N-PDUs from the same MS and other MSs. 8 levels of data priority are defined where 0 is the lowest and 7 is the highest.

#### 30.2.3.5 PDU Priority

PDU priority affects LLC queue reordering and the MS's permission to use random access opportunities. 8 levels of PDU priority are defined where 0 is the lowest and 7 is the highest priority.

#### 30.2.3.6 Data Importance

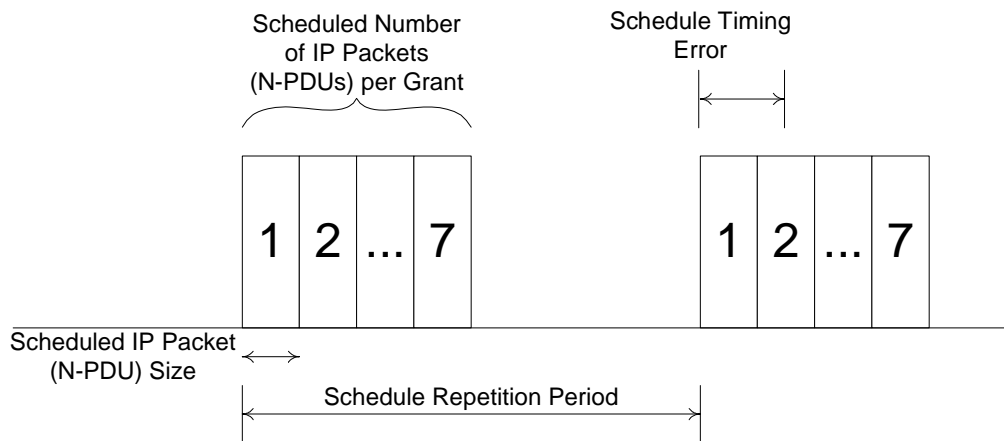

Data Importance allows the SNDCP the option to delete or cancel untransmitted lower importance N-PDUs in circumstances where buffer overflow might otherwise occur. Data Importance has three levels, Low, Medium and High.

#### 30.2.3.7 Scheduled Access Option

Scheduled access allows the application to reserve a periodic schedule of bandwidth appropriate to the application's requirements. Only the real-time and telemetry service classes may request regular access from the network.

Four attributes are defined to allow specification of the required schedule. Figure 30.5 illustrates the relationship between these attributes. Timing is always described with respect to the slot duration of 65/6 ms:

- Schedule Repetition Period - the number of slot durations between each schedule grant. Valid values are 4 (56,67 ms) to 706 (10 s).
- Scheduled number of IP Packets (N-PDUs) per grant - Each grant can consist from 1 up to 7 IP packets.
- Scheduled IP Packet (N-PDU) size - the size of the IP packet (N-PDU). This may be from 1 to 2 002 octets and may be specified separately for each IP packet within the grant.
- Schedule Timing Error - This allows the specification of a tolerated delay relative to the scheduled slot granting time. This is measured in slot durations and can be specified to be  $\leq 1$  to  $\leq 128$  slot durations. Note that the Scheduled Repetition Period is maintained and that Schedule Timing Error does not accumulate on each schedule grant.

**Figure 30.5: Scheduled Access**

### 30.2.3.8 CONTEXT\_READY timer

For a PDP context, the CONTEXT\_READY time is the duration for which the PDP context is actively transferring data. Upon the expiration of the CONTEXT\_READY time the SwMI is free to reallocate resources to other active PDP contexts. Valid values are:

- track READY timer;
- 200 ms;

### 30.2.3.9 Escalated Priority

Where an application may require to send temporary higher priority data, the MEX provides a means for the application to specify this. This is commonly used in the TCP header where the URG flag is utilized to indicate the highest urgency in transferring the packet.

A mechanism is also provided for the application to mark escalated priority within the IP header to allow the use of other transport protocols such as UDP. Bit 5 of the Differentiated Services Code Point field (DSCP) is utilized (according to the Local Use definition given by IETF RFC 2474 [43]).

The following two options are available for the application to mark a packet for escalated priority:

- Bit 5 of DSCP in the IP Header is set; and
- A TCP protocol is used and the URG flag is set.

The MEX QoS Filter shall inspect the packet protocol field. If the packet protocol field is TCP then the URG flag is inspected. The MEX shall also inspect bit 5 of the DSCP IP Header field.

The PDU Priority, Data Priority and Data Importance added to the SN-DATA/SN-UNITDATA primitive is derived as follows for each IP packet to be transmitted on the uplink. Note that MEX\_SNDATA\_QOS\_TBL is not affected by this operation:

- a) Protocol field is not TCP and DSCP bit 5 is not set - use the PDU Priority, Data priority and Data Importance from MEX\_SNDATA\_QOS\_TBL.
- b) Protocol field is not TCP and DSCP bit 5 is set - increase PDU Priority and Data priority by 2 from the appropriate values stored in MEX\_SNDATA\_QOS\_TBL. Increase Data Importance by one point higher over the value stored in MEX\_SNDATA\_QOS\_TBL.
- c) Protocol field is TCP, DSCP bit 5 is not set and URG flag is not set - use the PDU Priority, Data priority and Data Importance from MEX\_SNDATA\_QOS\_TBL.
- d) Protocol field is TCP, DSCP bit 5 is not set and URG flag is set - increase PDU Priority and Data priority by 1 from MEX\_SNDATA\_QOS\_TBL. Increase Data Importance by one point higher over the value stored in MEX\_SNDATA\_QOS\_TBL.
- e) Protocol field is TCP, DSCP bit 5 is set and URG is not set - increase PDU and Data priority by 1 from MEX\_SNDATA\_QOS\_TBL. Increase Data Importance by one point higher over the value stored in MEX\_SNDATA\_QOS\_TBL.
- f) Protocol field is TCP, DSCP bit 5 is set and URG flag is set - increase PDU and Data priority by 2 from MEX\_SNDATA\_QOS\_TBL. Increase Data Importance by one point higher over the value stored in MEX\_SNDATA\_QOS\_TBL.

Where it is not possible to increase PDU Priority, Data Priority or Data Importance, the highest value will be used. PDU Priority shall not exceed the returned PDU Priority max as specified by the SN-NSAPI Alloc Cnf when the PDP context was created.

Whilst this escalation is only appropriate for the TETRA air interface, the MEX shall optionally reset bit 5 of the DSCP before forwarding the packet on to any further hops in the IP network. If this option is active, MEX should reset bit 5 of DSCP before transferring the packet to the SNDSCP on the uplink and also before forwarding any downlink packets to the application. This option, by default, shall not reset bit 5 of DSCP. The option to enable the reset of bit 5 of DSCP is given during PDP context creation and is provided to avoid any limitation in the wider usage of Diffserv in an end to end communication.

By default the use of Bit 5 of DSCP for escalated priority shall be disabled. Usage can be enabled by the application during the MEX\_CONNECT procedure.

The SwMI may also provide escalated priority functionality in order to maintain escalated priority on both air interfaces of an MS to MS communication.

### 30.2.4 Definition of MEX states and state transitions

#### 30.2.4.1 General

At the highest level each transaction flow with the MEX layer has two major states as shown in figure 30.6. Each transaction flow is identified by "MEX Handle" which can represent the specific "MEX mode" by request. This allows multiple control and data streams to the MEX allowing the ability to transact across multiple logical PEI connections (PCONs) and to allow the instantiation and representation of multiple MS IP addresses in the TE2.

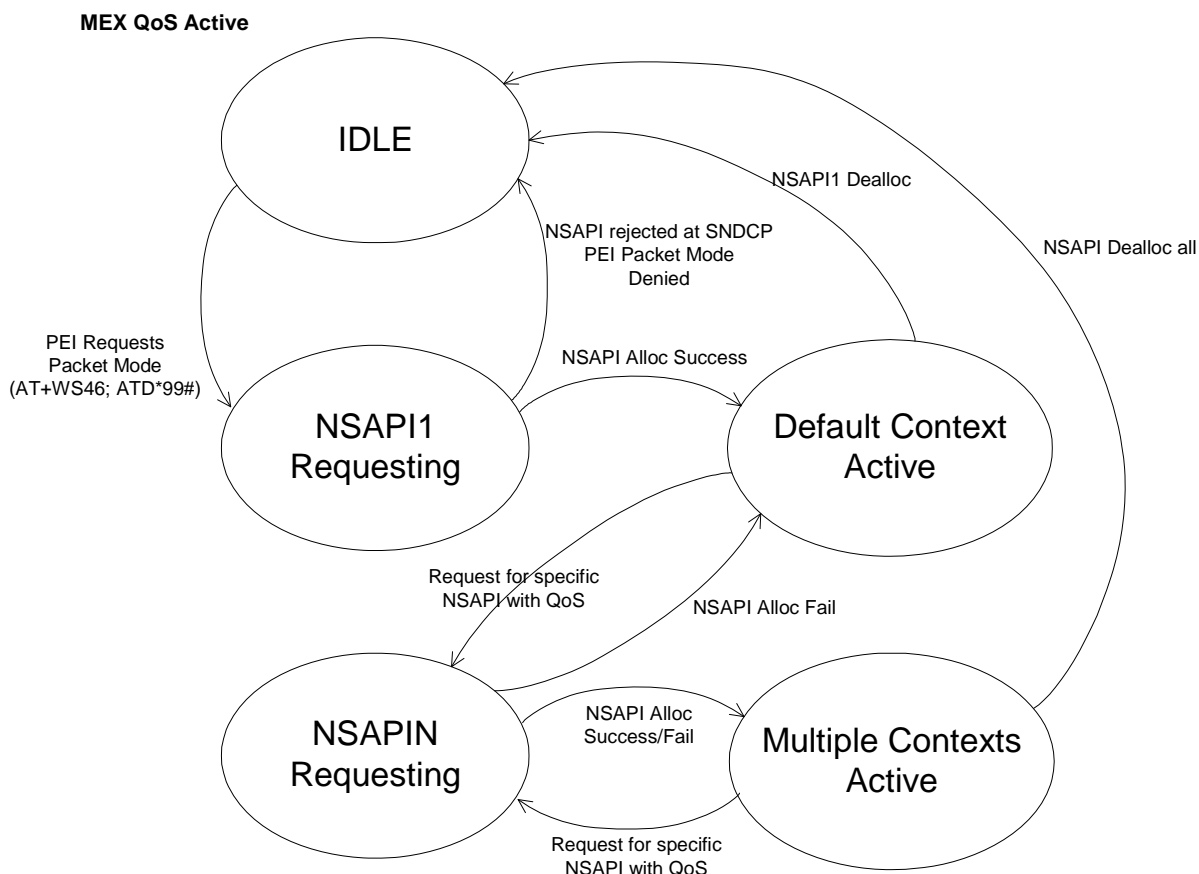

**Figure 30.6: Activating, Bypassing MEX QoS features using MEX Handle**

Individual states are described as follows:

- Use MEX - All QoS functionality, including PDP service negotiation is managed by the MEX Layer; and
- Bypass to SNDCP - All SNDCP services are directly accessible to the user application via the PEI.

Within the Use MEX state, the following state machine given in figure 30.7 elaborates the use of the default background context for the support of legacy applications.

**Figure 30.7: PDP context creation state machine**

Individual states are described as follows:

- IDLE - No NSAPIs are active, PEI only has one PCON in AT mode only;
- NSAPI1 Requesting - A Default, background class NSAPI is requested (MEX QoS Class = 0);
- Default Context Active - Equivalent Legacy Context. All data is routed through this basic NSAPI;
- NSAPIN Requesting - The application has requested another PDP context; and
- Multiple contexts active - Data is routed appropriately via the requested PDP contexts.

### 30.2.4.2 Secondary PDP contexts

The concept of secondary PDP contexts is defined at the SMDCP to allow for different applications with different QoS requirements to operate over a PDP context with the same MS IP address. The MEX-CONNECT primitive has provision to request either a new MS IP address or attach a new application with differing QoS requirements to an existing IP address. It is the MEX responsibility to ensure that the appropriate SMDCP transactions occur to request either the primary or secondary NSAPI appropriately.

### 30.2.4.3 MEX QoS Filter and Address/NSAPI mapping tables

Four tables, internal to MEX, are defined in order to facilitate operation of the MEX QoS Filter, the use of NSAPI and IP addresses and parameters for compilation of the SN-DATA/SN-UNITDATA primitives.

Table 30.4 illustrates MEX\_CONTEXT\_TBL table. MEX\_CONTEXT\_TBL is used to identify relationships between active PDP contexts. MEX\_CONTEXT\_TBL is used initially to store the unique MEX\_Handle, when a particular MEX\_Handle successfully initiates a PDP context, the MS IP address and associated NSAPI is stored. As the applications are only aware of IP Addresses and do not concern with NSAPI numbers, the MEX uses the mapping between MS IP Address and Primary NSAPI in order to facilitate the correct formulation of SN NSAPI Alloc requests for secondary PDP contexts. Successful creation of secondary PDP contexts are entered into the MEX\_CONTEXT\_TBL table 30.4.

**Table 30.4: MEX\_CONTEXT\_TBL**

| MEX Handle | MS IP Address | Primary NSAPI | Secondary NSAPI |
|------------|---------------|---------------|-----------------|
| ....       | ....          | ....          | ....            |
| ....       | ....          | ....          | ....            |

Table 30.5 illustrates the MEX\_QOS\_FILTER\_TBL table. Upon successful creation of a PDP context, MEX\_QOS\_FILTER\_TBL is updated with the Uplink Destination Port Range and filter type (with optional Peer Destination IP Address), or DSCP, Filter Type as specified by MEX QoS Filter in MEX-CONNECT. The Upper and Lower MEX QoS Class for Uplink and Downlink are also stored to allow MEX to renegotiate QoS parameters upon a network initiated SN NSAPI Modify as described in clause 30.3.4.

**Table 30.5: MEX\_QOS\_FILTER\_TBL**

| NSAPI | Uplink Destination Port Range | Peer Destination IP Address | DSCP | DSCP Priority Escalate Option | Filter Type | QoS Class Uplink Lower | QoS Class Uplink Upper | QoS Class Downlink Lower | QoS Class Downlink Upper |
|-------|-------------------------------|-----------------------------|------|-------------------------------|-------------|------------------------|------------------------|--------------------------|--------------------------|
| ....  | ....                          | ....                        | .... | ....                          | ....        | ....                   | ....                   | ....                     | ....                     |
| ....  | ....                          | ....                        | .... | ....                          | ....        | ....                   | ....                   | ....                     | ....                     |

Table 30.6 illustrates the MEX\_QOS\_AUTOFILTER\_TBL table. When "MEX Transaction Type" is specified in MEX-CONNECT or MEX-MODIFY as "Uplink Automatic Filter", MEX\_QOS\_AUTOFILTER\_TBL stores the details required to automatically generate entries into MEX\_QOS\_FILTER\_TBL from downlink packets. For each NSAPI, a destination Port Range and filter type is specified (with optional downlink Source IP address). Entries in MEX\_QOS\_FILTER\_TBL are updated based upon the following mappings:

- uplink packet Destination port - from the source port of the downlink packet; and

- uplink Peer Destination IP Address - from the source IP address of the downlink packet.

**Table 30.6: MEX\_QOS\_AUTOFILTER\_TBL**

| NSAPI | Downlink Destination Port Range | Downlink Source (Peer) IP address | Filter Type |
|-------|---------------------------------|-----------------------------------|-------------|
| ....  | ....                            | ....                              | ....        |
| ....  | ....                            | ....                              | ....        |

Table 30.7 illustrates MEX\_SNDATA\_QOS\_TBL table. During MEX-CONNECT and MEX-MODIFY, MEX PDU priority, MEX Data Priority and Data Importance are specified through entries of MEX QoS Class. These figures are stored in MEX\_SNDATA\_QOS\_TBL to allow MEX to automatically fill the optional fields within the SN-DATA primitive for uplink packets.

**Table 30.7: MEX\_SNDATA\_QOS\_TBL**

| NSAPI | MEX PDU Priority | MEX Data Priority | MEX Data Importance |
|-------|------------------|-------------------|---------------------|
| ....  | ....             | ....              | ....                |
| ....  | ....             | ....              | ....                |

## 30.3 MEX Procedures

### 30.3.1 Services provided by the protocol and QoS negotiations

MEX performs the following functions:

- processing PDP context activation, modification and PDP context deactivation requests;
- MEX precedence handling;
- handling the QoS modification requests originating from the SMDCP layer and the MT and TE applications;
- mapping of SN primitives received from the network layer into corresponding MEX messages to be passed to the MT and TE applications via the saps; and
- routing TE2 and internal MT2 application data, to and from the SMDCP layer.

### 30.3.2 MEX access procedure

MEX-HANDLE is used to request and deallocate a handle from MEX and to also indicate whether any subsequent MEX communication should be dealt with by the MEX or routed direct to the SMDCP.

**Figure 30.8: Obtaining a handle for use with MEX procedures**

Each numbered step in figure 30.8 is explained in the following list:

- 1) MEX-HANDLE Req is sent to the MEX requesting a "MEX Mode".
- 2) MEX-HANDLE Cnf returns the "MEX Handle" which is to be used in subsequent MEX primitives. "MEX Handle" may also be returned as 0xFF which is used to indicate a failure to supply a valid Handle.

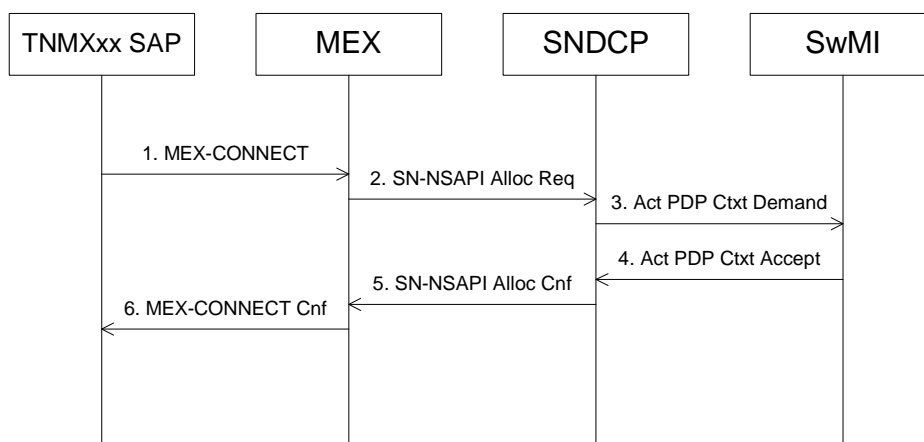

MEX primitives used without first using MEX-HANDLE can only originate from the default PCON and shall set a default handle of 0 and shall be handled by the MEX layer for provisioning of the Legacy context (ATD\*99# equivalent).

MEX-HANDLE used where "MEX Mode" is "Deallocate Handle", shall tear down all associated PDP contexts.

A MEX Handle is Deallocated only upon request or if the MS is powered off.

### 30.3.3 MEX-CONNECT Procedure

MEX-CONNECT is used to initiate a PDP context with a set of QoS parameters.

**Figure 30.9: MEX-CONNECT procedure**

Each numbered step in figure 30.9 is explained in the following lists with respect to whether MEX is utilized or bypassed based upon the MEX Mode associated with the "MEX Handle" which is used.

MEX Mode is "Use MEX":

1. MEX-CONNECT Req is sent to MEX with a MEX Handle, Port Range, transaction type and MEX QoS Class range and MEX PDP Type.
2. MEX looks up the QoS parameters from the internal MEX QoS Class table using parameter MEX QoS Class Upper. Firstly, the QoS parameters of currently active PDP contexts which have been initiated by MEX are investigated to assess the possibility to use a currently active PDP context. Step 2.1 shall be followed if a currently active PDP context is to be used:
  - 2.1. The procedures described in clause 30.3.4 are followed (without the originating MEX-MODIFY) taking into account the combined QoS of all applications currently using the PDP context including the application which has made the MEX-CONNECT request. This shall ensure that all applications using the chosen PDP context can remain within their requested MEX QoS Class range. Throughput parameters shall always be modified.
  - 2.2. If the current MEX-CONNECT cannot use an existing PDP context the MEX sends a full SN-NSAPI Alloc Req to SNDCP. If the QoS Manager or application requires a new IP address (MEX PDP Type), parameter NSAPI is automatically chosen numerically from the unallocated pool of NSAPI 1 to 14. If PDP address is present, PDP Type is set to IPv4 (static address). If PDP Type is specified as Primary NSAPI (secondary PDP context requested), the MEX shall lookup the NSAPI from MEX\_CONTEXT\_TBL table and supply the primary NSAPI appropriately in SN-NSAPI Alloc. If MEX Handle is 0, the default MEX QoS Class 0 shall be used. If MEX Data Priority Flag Reset is present then the QoS filter is enabled to reset bit 5 of DSCP upon data transfer.

3. SNDCP demands the PDP context from SwMI.
4. The SwMI may set its Downlink QoS filter as requested. SwMI replies with a success or failure.
5. SNDCP notifies MEX via SN-NSAPI Alloc Cnf. MEX inspects the returned QoS parameters and compares with the values of the MEX QoS Class table pointed to by "MEX QoS Class Lower". If one or more of the returned QoS parameters are returned specifying a lower QoS capability than those specified by "MEX QoS Class Lower" then the MEX-MODIFY procedure is subsequently used with parameters of "MEX QoS Class Lower". Step 6 is then returned accordingly.
6. Upon successful creation or attachment to an existing PDP context, MEX returns MEX-CONNECT Cnf with details of the final QoS parameters in operation. If an existing PDP context is modified as described in step 2.1 then all applications originally using the modified PDP context shall receive a MEX-MODIFY Ind as for the Network initiated MEX-MODIFY described by step 8 of figure 30.13 (clause 30.3.4). MEX updates MEX\_CONTEXT\_TBL table. If MEX transaction type is "Uplink Filter" MEX updates MEX\_QOS\_FILTER\_TBL table. If MEX transaction type is "Uplink Automatic Filter", MEX updates MEX\_QOS\_AUTOFILTER\_TBL table. If a subsequent MEX-MODIFY is attempted in step 5 and returns QoS parameters specifying a lower QoS capability than those specified by "MEX QoS Class Lower" MEX-CONNECT Cnf, MEX Connect Report shall equal Failure and MEX Connect reject Cause shall equal Requested QoS not available. An additional SN-NSAPI Dealloc req shall be sent to the SNDCP to deactivate the corresponding PDP context.

MEX mode is "Bypass to SNDCP":

- 1) MEX-CONNECT is sent to MEX with all PDP Context creation and QoS parameters except "MEX Precedence". MEX Transaction types "uplink filter" and "Automatic uplink filter" are not available.
- 2) MEX directly forwards, or if necessary, reformats and forwards the request as SN NSAPI Alloc Req to SNDCP.
- 3) SNDCP demands the PDP context from SwMI.
- 4) SwMI replies with a success or failure.
- 5) SNDCP notifies MEX via SN-NSAPI Alloc Cnf.
- 6) MEX directly forwards or, if necessary, reformats and forwards SN NSAPI Alloc Cnf as MEX-CONNECT Cnf.

### 30.3.4 MEX-MODIFY Procedure

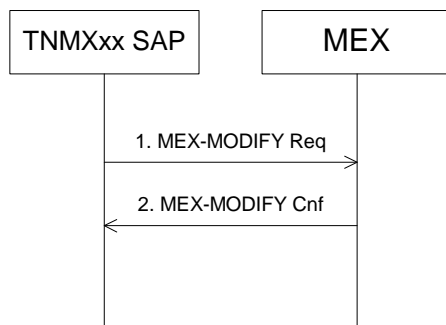

MEX-MODIFY can be either MS or Network initiated. For an MS initiated MEX-MODIFY, depending upon which QoS parameters are required to change, there are three different procedures which may be followed as shown in figures 30.10, 30.11 and 30.12. Depending upon the combination of QoS parameters which are required to change the functionality of figures 30.10, 30.11 and 30.12 will be combined.

By default, the description below assumes that MEX-HANDLE represents MEX Mode as "Use MEX". Exceptions are described throughout.

The following sequence charts illustrate all distinct combinations of transactions required to achieve MEX-MODIFY functionality. In many cases, combinations of these transactions are required. Where this is necessary, only one MEX-MODIFY Cnf should be returned for each MEX-MODIFY Req.

Where a PDP context is shared by several applications, a MEX-MODIFY Req from a single application should not infer a lower QoS on to the sharing applications.

Figure 30.10 illustrates the transactions required with MEX where MEX Precedence, PDU Priority, Data Importance and/or MEX QoS Filter, has changed or MEX Filter Operation is present.

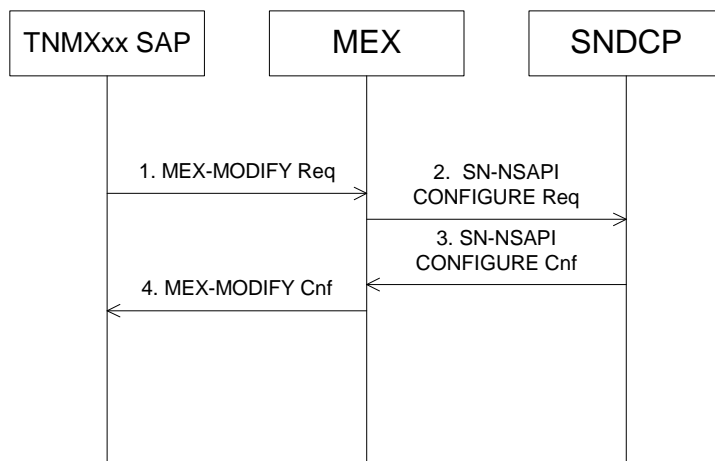

**Figure 30.10: MEX-MODIFY where MEX Precedence, PDU Priority, Data Importance and/or MEX QoS Filter, has changed or MEX Filter Operation is present**

Each numbered step in figure 30.10 is explained in the following list:

1. MEX-MODIFY Req is sent to MEX where MEX Precedence, PDU Priority and/or Data Importance, uplink MEX QoS Filter has changed or MEX Filter Operation is present. MEX internally modifies its MEX\_QOS\_FILTER\_TBL, MEX\_QOS\_AUTOFILTER\_TBL and MEX\_SNDATA\_QOS\_TBL and MEX Precedence buffers.
2. MEX-MODIFY Cnf is returned.

This transaction is not appropriate where MEX-HANDLE represents MEX Mode as "Bypass to SNDCP".

Figure 30.11 illustrates the transactions required with MEX when only "MEX Data Priority" has changed.

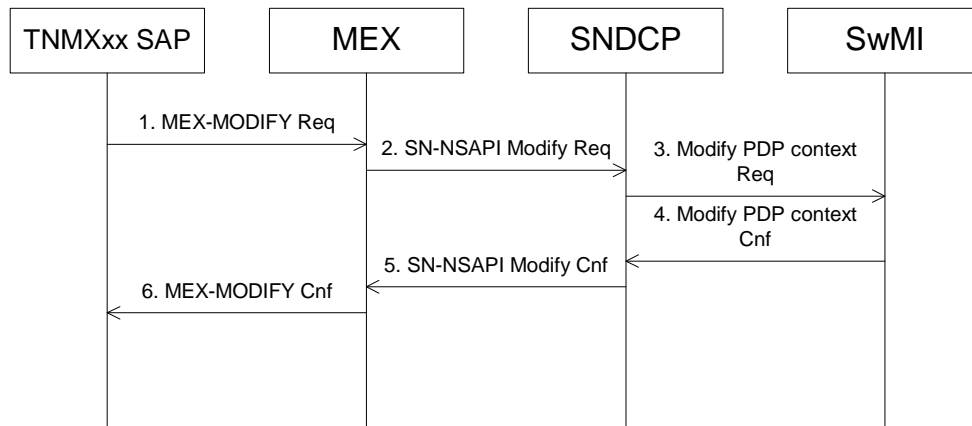

**Figure 30.11: MEX-MODIFY where Data Priority has changed**

Each numbered step in figure 30.11 is explained in the following list:

1. MEX-MODIFY Req is sent to MEX where Data Priority has changed.
2. SN-NSAPI CONFIGURE Req is sent to SNDCP with the requested default Data Priority.
3. SNDCP agrees a change in default Data Priority with the SwMI. SN-NSAPI CONFIGURE Cnf is then returned to MEX. Where "NSAPI Modify Report" is returned with Success, MEX updates MEX\_SNDATA\_QOS\_TBL.
4. MEX-MODIFY Cnf is returned.

Where MEX-HANDLE represents MEX Mode as "Bypass to SNDCP", this transaction is only applicable where ONLY Data Priority has changed.

Figure 30.12 illustrates the transactions required with MEX where other QoS parameters have changed or "MEX NSAPI Usage" is requested.

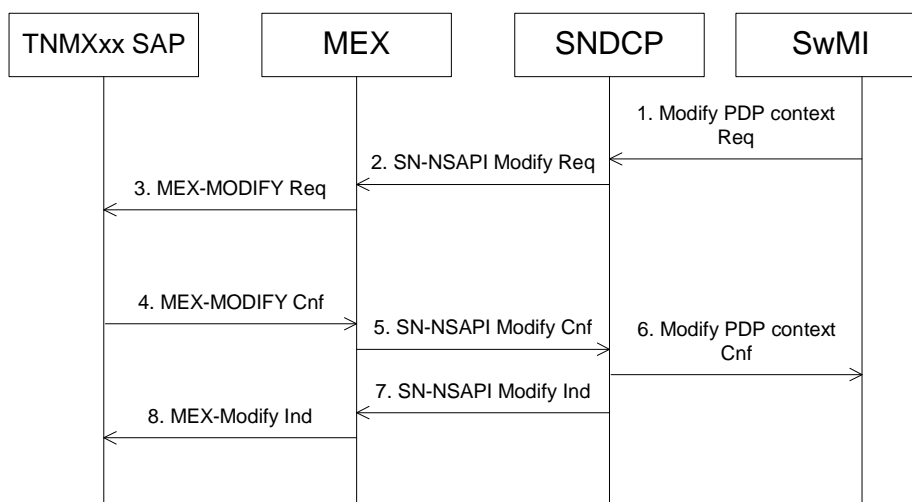

**Figure 30.12: MS initiated MEX-MODIFY**

Each numbered step in figure 30.12 is explained in the following list:

1. MEX-MODIFY Req is sent to MEX. If "MEX Data Priority" has changed, the SN-NSAPI CONFIGURE procedure shall be carried out according to Figure 30.11 above in advance of the following steps except for MEX MODIFY Cnf which shall be sent as a single instance in step 6 below. This extra step is not applicable where MEX-HANDLE represents MEX Mode as "Bypass to SNDCP".
2. SN-NSAPI MODIFY Req is sent to SNDCP with the requested modifications to NSAPI QoS Negotiation.
3. SNDCP requests modifications from SwMI.
4. SwMI may update its QoS Filter based upon any new downlink filter parameters. SwMI confirms modifications to SNDCP.
5. SN-NSAPI MODIFY Cnf is returned to MEX. On success, MEX updates its internal tables and/or MEX precedence buffers appropriately.
6. MEX-MODIFY Cnf is returned.

Figure 30.13 illustrates a network initiated MEX-MODIFY.

**Figure 30.13: Network initiated MEX-MODIFY**

Each numbered step in figure 30.13 is explained in the following list:

1. SwMI Requests a modification to the PDP context.
2. SNDTCP forwards appropriately to MEX using SN-NSAPI Modify Req. MEX may lookup the requested QoS modification to check if this specifies a higher QoS capability than the appropriate "MEX QoS Class Lower" entry for the NSAPI. Should this be true, steps 3 and 4 are bypassed. Where MEX-HANDLE represents MEX Mode as "Bypass to SNDTCP", SN-NSAPI Modify Req is forwarded directly using MEX-MODIFY Req in step 3.
3. The application is notified of the requested modification using MEX-MODIFY Req.
4. The application replies using MEX-MODIFY Cnf. Where MEX-HANDLE represents MEX Mode as "Bypass to SNDTCP", SN-NSAPI Modify Cnf is forwarded directly.
5. MEX forwards the confirmation to SNDTCP using SN Modify Cnf.
6. SNDTCP forward confirmation to SwMI.
7. Upon a successful modification SN NSAPI Modify Ind is send to the MEX. MEX shall update its tables accordingly. Where MEX-HANDLE represents MEX Mode as "Bypass to SNDTCP", SN-NSAPI Modify Ind is forwarded directly using MEX-MODIFY Ind in step 8.
8. Application is notified of the new QoS modification using MEX-MODIFY Ind. Note that this may the first indication to the application of any QoS modification should the new QoS parameters exceed the originally requested "MEX QoS Class Lower" as described in step 2.

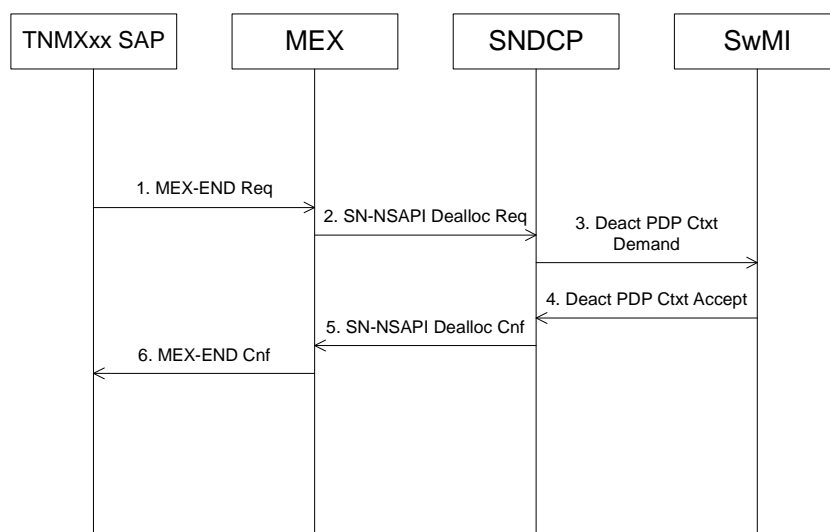

Where a PDP context modification is initiated by the network and the PDP context is shared by multiple applications, each application shall receive a MEX-MODIFY Req with an appropriate proportion of the full PDP context throughput to the originating request. Each application shall reply with a MEX-MODIFY Cnf before step 5 can continue. Each application using the shared PDP context shall also receive the MEX-MODIFY Ind as described in step 8.

MEX-MODIFY Ind is also sent, unsolicited, direct from the MEX upon a change of the overall MEX Precedence ranking as described in clause 30.2.3.3.

### 30.3.5 MEX connection termination procedure

The following describes the procedure for terminating a PDP context. Termination can be either MS or Network initiated, both of which are described below.

Figure 30.14 illustrates an MS initiated PDP Context Deactivation.

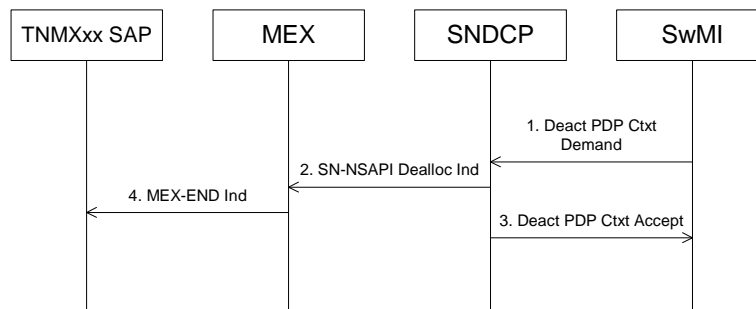

**Figure 30.14: MS initiated PDP Context Deactivation**

Each numbered step in figure 30.14 is explained in the following list:

1. The application on the MS initiates a MEX-END Request. If Deactivation type is "Deactivate all MEX Contexts" then steps 2 to 5 shall be carried out for each active PDP context which has been created by the MEX layer.
2. SN-NSAPI Dealloc Req is sent to SNDPCP.
3. Deactivate PDP Context Demand is sent to SwMI.
4. SwMI replies with acceptance.
5. SN-NSAPI Dealloc Cnf Confirms to MEX. MEX removes all appropriate entries from internal tables.
6. MEX informs the application of successful deactivation.

Figure 30.15 illustrates a Network initiated PDP Context Deactivation.

**Figure 30.15: Network initiated PDP Context Deactivation**

Each numbered step in figure 30.15 is explained in the following list:

1. SwMI Demands PDP Context Deactivation.
2. SNDPCP forwards the Deactivation using SN-NSAPI Dealloc Ind.
3. MEX determines all active MEX Contexts for the Deactivation of the requested NSAPI and removes all appropriate entries from internal tables.
4. MEX-END Ind notifies the application of the deactivation of either a single or all PDP contexts. Where a single NSAPI deactivation is given by SN-NSAPI Dealloc and multiple MEX Contexts are active on the single NSAPI, a MEX-END Ind shall be sent for each appropriate MEX Context.

### 30.3.6 MEX QoS Abstract Class Table Management

Figure 30.16 describes the procedure for accessing the MEX QoS Class table.

**Figure 30.16: Managing the MEX QoS Abstract Class table**

Each numbered step in figure 30.16 is explained in the following list:

1. The application requests indication, update and or locking of a MEX QoS Class entry. MEX QoS Class Access is used to request the read, write and lock functionality. If MEX QoS Class Access is "Write and Lock" the specified MEX QoS class entry shall only be writeable when the specified MEX Handle is stated. MEX QoS Class Access "Unlock" shall be used to release the entry for subsequent access using any MEX Handle.
2. MEX returns confirmation that the entry has been updated (if applicable) together with the full list of QoS parameters in the requested class.

A lock on a MEX QoS Class entry shall be automatically released upon the termination of all contexts which use the MEX QoS Class entry. All locks shall be released upon power off of the MS.

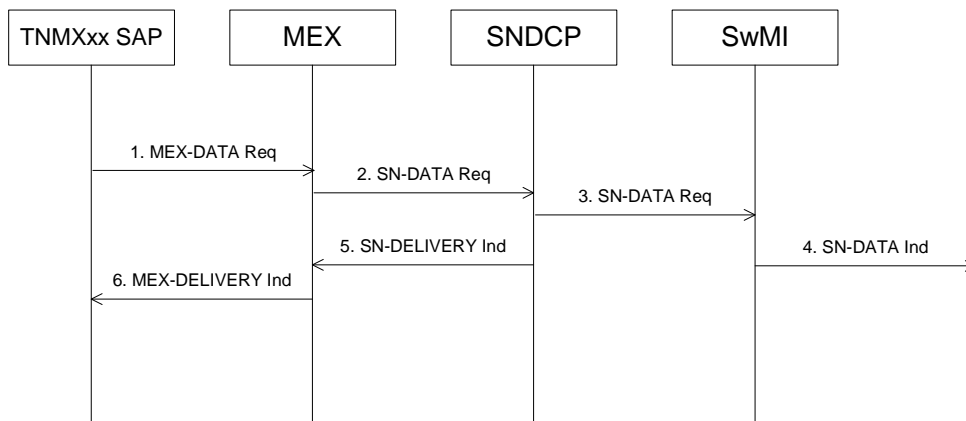

### 30.3.7 MEX data routing procedure

#### 30.3.7.1 Uplink Data Service

The following describes the procedure for data routing in the uplink service.

When using MEX services and an acknowledged service is utilized, the MEX shall allocate and keep track of SN-DATA handles paired with SN-DELIVERY returns. Where SN-DELIVERY returns with either Failure or Deletion by SNDCP report, or no SN-DELIVERY is received then the MEX shall return the full IP header together with the first 64 bytes of data back to the application through the PEI to allow for implementation of ICMP signalling support in the TE2 or MT2 IP stack.

Note that in the following description, the SNDCP primitive SN-DATA is described. Where an unacknowledged service is used, the treatment of SN-DATA should be replaced by SN-UNITDATA.

**Figure 30.17: MS initiated Data Routing**

Each numbered step in figure 30.17 is explained in the following list:

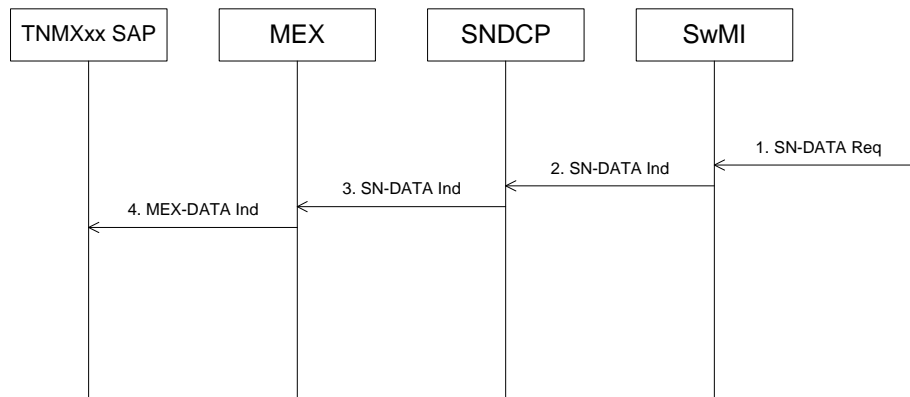

1. MEX-DATA Req is either an IP packet to be transferred to the network or a MEX-BYPASS DATA Req encapsulating a full SNDCP SN-DATA Req primitive.
2. MEX prepares and sends an SN-DATA Req to SNDCP. The MEX inspects the Destination port, Destination Address and DSCP of the IP packet and decides which NSAPI should be used, by using MEX\_QOS\_FILTER\_TBL. SN-DATA Handle is assigned and recorded ready for checking of a receipt of SN-DELIVERY. PDU Priority, Data Priority, Data Importance of SN-DATA are set according the appropriate entry in MEX\_SNDATA\_QOS\_TBL. The IP packet is inspected and priority escalated appropriately according to clause 30.2.3.9. If the MEX recognizes an excess of data over and above any accepted schedule, the MEX sets the Schedule Surplus flag. (see clause 28.3.5.6). Where MEX-HANDLE represents MEX Mode as "Bypass to SNDCP", MEX-DATA Req is forwarded, with any necessary reformatting, directly to SNDCP.
3. SN-DATA Req is sent across the air interface to the SwMI.
4. SwMI forwards SN-DATA Ind to the IP network.

5. If an acknowledged service is utilized, SN-DELIVERY is sent to MEX. MEX checks the SN-DELIVERY Handle against those recorded at step 2.
6. If SN-DELIVERY Delivery Report is "Failure" or "Deleted or Cancelled by SNDSCP" then MEX DELIVERY is sent to the application.

### 30.3.7.2 Downlink Data Service

The following describes the procedure for data routing in the downlink service.

Note that in the following description, the SNDSCP primitive SN-DATA is described. Where an unacknowledged service is used, the treatment of SN-DATA should be replaced by SN-UNITDATA.

**Figure 30.18: SwMI initiated Data Routing**

Each numbered step in figure 30.18 is explained in the following list:

1. SwMI receives SN-DATA Req from the network.
2. SN-DATA Ind is received over the air interface by SNDSCP.
3. SN-DATA Ind is sent to MEX. The IP packet is inspected for Destination port and source IP address. MEX\_QOS\_AUTOFILTER\_TBL is compared and MEX\_QOS\_FILTER\_TBL is updated accordingly as described in clause 30.2.4.3. If the option MEX Escalate Flag Reset was present at MEX-CONNECT for the NSAPI, the MEX shall reset bit 5 of DSCP prior to forwarding the packet (clause 30.2.3.9).
4. MEX forwards the data to the appropriate SAP using MEX-DATA Ind containing either an IP packet or MEX-BYPASS DATA Ind primitive.

### 30.3.7.3 Maximum Transmission Unit

Where MEX-DATA on the uplink represents an IP packet which exceeds the state Maximum Transmission Unit, a MEX-DELIVERY Ind shall be returned to the application to allow the possibility to utilize the ICMP Destination unreachable Message (IETF RFC 792 [i.14]) to indicate through the MT2 or TE2 IP stack. Path MTU discovery (PMTUD) (IETF RFC 1191 [i.15]) can therefore be utilized by the TE2 IP stack to determine the appropriate MTU to use.

### 30.3.7.4 Scheduled access

The MEX shall remain aware of any uplink MEX-DATA request primitives which are intended to make use of the scheduled access service. The MEX shall keep a count and detect any increase in the quantity of data exceeding the requested schedule. In such case where the schedule is exceeded, the MEX shall send extra SN-DATA with the Schedule Surplus Flag set, as appropriate, so as not to lose any data.

### 30.3.7.5 MEX-QOS

The MEX-QOS request primitive is a direct mapping to SN-QoS in the SNDCP and is retained for backward compatibility with previous versions of SNDCP, and is applicable only to  $\pi/4$ -DQPSK modulation. The optional MEX NSAPI QoS negotiation parameter included in the MEX-CONNECT and MEX-MODIFY primitives has more general applicability, and should be used instead of the MEX-QOS request primitive.

MEX-QOS is only available at TNMXIT\_SAP and not available through the PEI via TNMXPI SAP.

### 30.3.7.6 Packet mode Paging

The MEX-PAGE primitive is a direct mapping to SN-PAGE in the SNDCP.

MEX-PAGE is only available at TNMXIT\_SAP and not available through the PEI via TNMXPI SAP.

## 30.4 MEX service description

### 30.4.1 Introduction

Clause 30.4 describes the services offered by the Multimedia Exchange (MEX) entity for the voice plus data TETRA layer 3 air interface.

### 30.4.2 Services offered

MEX shall be a service provider for packet data users.

The services offered shall be:

- receiving MEX access requests from the MT and TE applications;
- filtering TE and MT application data to the appropriate PDP context and QoS by monitoring the port numbers, IP addresses and DSCP encapsulated within IP datagrams;
- receiving the QoS requirements from the MT and TE applications;
- negotiating application QoS requirements with the SNDCP layer;
- management of MEX precedence specified by the MT and TE applications using internal buffering and a switching function; and
- providing feedback on the changing QoS values to the MT and TE applications.

### 30.4.3 Service Primitives

#### 30.4.3.1 General on service primitives

The services shall be provided using MEX messages to the PEI via TNMXPI SAP and MT2 internal applications via TNMXIT SAP. Access to the SNDCP primitives is via the SN-SAP. This clause describes the primitives and their parameters.

The MEX services consist of the following messages:

- MEX-CAPABILITY;
- MEX-CONNECT;
- MEX-DATA;
- MEX-DELIVERY;
- MEX-END;

- MEX-HANDLE;
- MEX-MODIFY; and
- MEX-QOSCLASS.

In parameter descriptions:

- C = Conditional;
- M = Mandatory; and
- O = Optional.

### 30.4.3.2 MEX-CAPABILITY

The parameters for the primitive MEX-CAPABILITY shall be as defined in table 30.8.

**Table 30.8: Parameters for the primitive MEX-CAPABILITY**

| <b>Parameter</b> | <b>Req</b> | <b>Ind</b> |
|------------------|------------|------------|
| MEX Handle       | M          | M          |
| MEX Capability   | M          | M          |

### 30.4.3.3 MEX-CONNECT

The parameters for the primitive MEX-CONNECT shall be as defined in table 30.9.

**Table 30.9: Parameters for the primitive MEX-CONNECT**

| Parameter   | Req                   | Cnf                   |
|---|-----------------------|-----------------------|
| MEX Handle  | M                     | M                     |
| MEX QoS Filter  | O                     | -                     |
| MEX QoS Class Uplink Upper  | C (see note 2)        | -                     |
| MEX QoS Class Uplink Lower  | C (see note 2)        | -                     |
| MEX QoS Class Downlink Upper  | O                     | -                     |
| MEX QoS Class Downlink Lower  | O                     | -                     |
| MEX Escalate DSCP5 Flag Enable  | O                     | -                     |
| MEX Escalate DSCP5 Flag Reset   | O                     | -                     |
| MEX Connect Report  | -                     | M                     |
| MEX Connect Reject Cause  | -                     | C (see note 6)        |
| Maximum Transmission Unit   | -                     | M                     |
| MEX PDP Type  | M                     | C (see note 5)        |
| MEX PDP Address   | C (see note 5)        | C (see note 5)        |
| NSAPI   | C (see note 3)        | -                     |
| DCOMP   | O (see notes 3 and 4) | O (see note 3)        |
| PCOMP   | O (see notes 3 and 4) | O (see note 3)        |
| NSAPI QoS Negotiation   | O (see notes 3 and 4) | O (see note 3)        |
| NSAPI Data Priority   | O (see notes 3 and 4) | -                     |
| PDU Priority Max  | -                     | C (see note 5)        |
| Mobile IPv4 Information   | -                     | C (see note 5)        |
| MEX Precedence  | -                     | C (see notes 2 and 8) |
| NOTE 1: Provided if mapping of data is filtered by both IP address and Port.  |                       |                       |
| NOTE 2: Only used if the "MEX Handle" was returned with MEX mode as "Use MEX".  |                       |                       |
| NOTE 3: Only used if the "MEX Handle" was returned with MEX mode as "Bypass to SNDSCP" and the values has changed. Refer to SN-NSAPI Alloc, refer to clause 28.2.3.1. |                       |                       |
| NOTE 4: Optional, refer to SN-NSAPI Alloc, refer to clause 28.2.3.1.  |                       |                       |
| NOTE 5: Shall be present, if MEX connect report is "Success (QoS parameter changed)". Refer to SN-NSAPI Alloc, refer to clause 28.2.3.1.                              |                       |                       |
| NOTE 6: Present if MEX Report is "Failure".   |                       |                       |
| NOTE 7: Not present if MEX Report is "Failure".   |                       |                       |
| NOTE 8: MEX Precedence for Cnf will return the overall ranking of MEX precedence rather than the requested MEX Precedence as described in clause 30.2.3.3.            |                       |                       |

### 30.4.3.4 MEX-BYPASS DATA

The parameters for the primitive MEX-BYPASS DATA shall be as defined in table 30.10.

**Table 30.10: Parameters for the primitive MEX-BYPASS DATA**

| Parameter   | Req            | Ind            |
|---|----------------|----------------|
| MEX Handle  | M (see note 1) | M (see note 1) |
| NSAPI   | C (see note 2) | C (see note 2) |
| Data Handle   | C (see note 2) | -              |
| PDU Priority  | C (see note 2) | -              |
| Data Priority   | C (see note 2) | -              |
| Data Importance   | C (see note 2) | -              |
| Schedule Surplus Flag   | C (see note 2) | -              |
| MEX N-PDU   | M              | M              |
| NOTE 1: The MEX Handle shall be set to "Bypass to SNDSCP".                          |                |                |
| NOTE 2: The parameter shall be present if MEX Handle represents "Bypass to SNDSCP". |                |                |

### 30.4.3.5 MEX-DELIVERY

The parameters for the primitive MEX-DELIVERY shall be as defined in table 30.11.

**Table 30.11: Parameters for the primitive MEX-DELIVERY**

| Parameter  | Ind            |
|--|----------------|
| MEX Handle   | M              |
| Data Handle  | C (see note 1) |
| MEX Delivery Report  | M              |
| MEX Delivery Header  | C (see note 2) |
| NOTE 1: Only present if MEX Handle represents "Bypass to SNDCP". |                |
| NOTE 2: Only present if MEX Handle represents "Use MEX".         |                |

### 30.4.3.6 MEX-END

The parameters for the primitive MEX-END shall be as defined in table 30.12.

**Table 30.12: Parameters for the primitive MEX-END**

| Parameter  | Req          | Ind          | Cnf          |
|--|--------------|--------------|--------------|
| MEX Handle   | M            | M            | M            |
| NSAPI  | C (see note) | C (see note) | C (see note) |
| MEX Deactivation Type  | M            | M            | M            |
| NOTE: Only present if MEX Handle represents "Bypass to SNDCP". |              |              |              |

### 30.4.3.7 MEX-HANDLE

The parameters for the primitive MEX-HANDLE shall be as defined in table 30.13.

**Table 30.13: Parameters for the primitive MEX-HANDLE**

| Parameter  | Req | Ind |
|------------|-----|-----|
| MEX Handle | M   | M   |
| MEX Mode   | M   | M   |

### 30.4.3.8 MEX-MODIFY

The parameters for the primitive MEX-MODIFY shall be as defined in table 30.14.

**Table 30.14: Parameters for the primitive MEX-MODIFY**

| Parameter                    | Req                   | Ind                   | Cnf                   |
|------------------------------|-----------------------|-----------------------|-----------------------|
| MEX Handle                   | M                     | M                     | M                     |
| MEX QoS Filter               | O                     | -                     | -                     |
| MEX Filter Operation         | O                     | -                     | -                     |
| MEX QoS Class Uplink Upper   | C (see note 1)        | -                     | -                     |
| MEX QoS Class Uplink Lower   | C (see note 1)        | -                     | -                     |
| MEX QoS Class Downlink Upper | C (see notes 1 and 7) | -                     | -                     |
| MEX QoS Class Downlink Lower | C (see notes 1 and 7) | -                     | -                     |
| MEX Modify Report            | -                     | -                     | M                     |
| MEX Modify Reject Cause      | -                     | -                     | C (see note 4)        |
| MEX NSAPI Usage              | O                     | -                     | -                     |
| NSAPI QoS Negotiation        | C (see notes 2 and 3) | C (see notes 2 and 3) | C (see notes 1 and 2) |
| Schedule Availability        | -                     | O                     | -                     |
| MEX Precedence               | -                     | C (see notes 1 and 6) | C (see notes 1 and 6) |

NOTE 1: Only used if the "MEX Handle" was returned with MEX mode as "Use MEX".  
 NOTE 2: Only used if the "MEX Handle" was returned with MEX mode as "Bypass to SNDCP".  
 NOTE 3: Optional as for SN-NSAPI Modify.  
 NOTE 4: Present if MEX Report is "Failure".  
 NOTE 5: Not present if MEX Report is "Failure".  
 NOTE 6: MEX Precedence for Ind and Cnf will return the overall ranking of MEX precedence rather than the requested MEX Precedence as described in clause 30.2.3.3.  
 NOTE 7: Only if SNDCP supports Asymmetric QoS.

### 30.4.3.9 MEX-PAGE

The parameters for the primitive MEX-PAGE shall be as defined in table 30.15.

**Table 30.15: Parameters for the primitive MEX-PAGE**

| Parameter         | Indication | Response |
|-------------------|------------|----------|
| NSAPI             | M          | M        |
| Reply requested   | M          | -        |
| PD service status | -          | M        |

### 30.4.3.10 MEX-QOS

The parameters for the primitive MEX-QOS shall be as defined in table 30.16.

**Table 30.16: Parameters for the primitive MEX-QOS**

| Parameter              | Request | Indication |
|------------------------|---------|------------|
| QoS requested          | M       | M          |
| QoS minimum            | M       | -          |
| QoS negotiated         | -       | M          |
| QoS negotiation result | -       | M          |

NOTE: It is recommended that this primitive is used only to set parameters within the MS SNDCP entity, to be used at a later stage during advanced link setup negotiation. This primitive should not in itself trigger the establishment or resetting of the advanced link.

### 30.4.3.11 MEX-QOSCLASS

The parameters for the primitive MEX-QOSCLASS shall be as defined in table 30.17.

**Table 30.17: Parameters for the primitive MEX-QOSCLASS**

| Parameter  | Req            | Cnf            |
|--|----------------|----------------|
| MEX Handle   | M              | M              |
| MEX QoS Class  | M              | M              |
| MEX QoS Class Access   | M              | M (see note 2) |
| MEX QoS  | C (see note 1) | M              |
| MEX Precedence   | C (see note 1) | M              |
| MEX Data Priority  | C (see note 1) | M              |
| MEX PDU Priority Max   | C (see note 1) | M              |
| MEX Data Importance  | C (see note 1) | M              |
| NOTE 1: Not present is MEX QoS Class Access is "Read".   |                |                |
| NOTE 2: "Read" is indicated if the MEX QoS Class is Read Only. "Write" is indicated if the "MEX QoS Class" entry has been updated. |                |                |

## 30.4.4 MEX Parameters

### 30.4.4.0 General

MEX Parameters are described in detail in the following list. Note that many parameters are derived directly from their original definition within clause 28. Some of these parameters have been modified for appropriate operation with the MEX layer primitives described above. Those which have modifications with respect to those defined in clause 28 are prefixed with "MEX". Those which are identical to the SNDCP parameters do not have this prefix.

#### 30.4.4.1 Data Handle

This parameter is only used in "Bypass to SNDCP" mode and mimics the SNDCP Data Handle parameter. See clause 28.1 for a full definition as applied to SN-DATA and SN-UNITDATA.

#### 30.4.4.2 Data Importance

This parameter is only used in "Bypass to SNDCP" mode and mimics the SNDCP Data Importance parameter. See clause 28.1 for a full definition as applied to SN-DATA and SN-UNITDATA.

#### 30.4.4.3 Data Priority

This parameter is only used in "Bypass to SNDCP" mode and mimics the SNDCP Data Priority parameter. See clause 28.1 for a full definition as applied to SN-DATA and SN-UNITDATA.

#### 30.4.4.4 DCOMP

This parameter may contain several different data compression methods, such as Recommendation ITU-T V.42bis [27], and their parameters negotiated with the peer entity.

#### 30.4.4.5 Maximum Transmission Unit

This is the maximum size of N PDU which may be presented by the MS service user to SNDCP for transport over the air interface. This typically represents the maximum size of IP packet (prior to adding SNDCP header and performing compression) which may be carried over the air interface.

#### 30.4.4.6 MEX Capability

- MEX Precedence is supported; or
- MEX Precedence is not supported.

#### 30.4.4.7 MEX Connect Reject Cause

- undefined;
- MS not provisioned for Packet Data;
- IPv4 not supported;
- IPv6 not supported;
- IPv4 dynamic address negotiation not supported;
- IPv6 stateful address autoconfiguration not supported;
- IPv6 stateless address autoconfiguration not supported;
- dynamic address pool empty;
- static address not correct;
- static address in use;
- static address not allowed;
- static IP address congestion;
- TETRA Packet Data not supported on this location area;
- TETRA Packet Data not supported on this network;
- temporary rejection;
- packet Data MS Type not supported;
- SNDCP version not supported;
- mobile IPv4 not supported;
- mobile IPv4 Co-located Care of Addresses not supported;
- maximum allowed PDP contexts per ITSI exceeded;
- user authentication failed;
- activation rejected by external PDN;
- access point name index not correct;
- no response from network;
- bad response from network;
- NSAPI not available;
- NSAPI already allocated;
- requested minimum peak throughput not available;
- scheduled access not supported;
- requested schedule not available;
- requested QoS not available;
- secondary PDP contexts not supported;
- primary PDP context does not exist;

- asymmetric QoS not supported;
- automatic QoS filter not supported;
- specified QoS filter not supported; or
- QoS filter type not supported; or
- QoS filter not available for primary PDP context; or
- SNDCP service temporarily not available.

#### 30.4.4.8 MEX Connect Report

- failure;
- success (not used in "Bypass to SNDCP" mode); or
- success QoS Parameters changed.

#### 30.4.4.9 MEX Deactivation Type

- deactivate all NSAPIs;
- deactivate all MEX Contexts (NOTE: only in Use MEX mode); or
- deactivate all contexts associated with the MEX Handle given in the primitive.

#### 30.4.4.10 MEX Delay Class

- Low;
- Moderate;
- High; or
- Unpredictable.

#### 30.4.4.11 MEX Delivery Header

This parameter consists of the full IP header plus the first 64 bytes of data of the IP packet for delivery failed. The intended provision of this data is to allow the possibility to utilize the ICMP Destination Unreachable Message (IETF RFC 792 [i.14]) to indicate through the TE2 or MT2 IP stack.

#### 30.4.4.12 MEX Delivery Report

- Success;
- Failure;
- Deleted or cancelled by SNDCP;
- Packet exceeds MTU (Only used if MEX Handle represents "Use MEX"); or
- Packet was Surplus to Schedule (Only used if MEX Handle represents "Use MEX").

#### 30.4.4.13 MEX Escalate DSCP5 Flag Enable

Parameter is present in MEX-CONNECT to specify that the Diffserv bit 5 shall be used for priority escalation as described in clause 30.2.3.9.

#### 30.4.4.14 MEX Escalate DSCP5 Flag Reset

Parameter is present in MEX-CONNECT to specify that the Diffserv bit 5 shall be reset before an IP packet is forwarded from the MEX.

#### 30.4.4.15 MEX Filter

- a range of IP Ports; or
- a DSCP.

#### 30.4.4.16 MEX Filter Operation

- add this QoS filter to any existing QoS filter for this PDP context;
- replace any existing QoS filter for this PDP context by this QoS filter; or
- remove this QoS filter from the existing QoS filter for this PDP context.

#### 30.4.4.17 MEX Filter Type

- Automatic;
- All types of ports;
- UDP Only;
- TCP Only; or
- Diffserv.

NOTE: Diffserv is not applicable to either the "Automatic Uplink Filter" or "Automatic Downlink Filter" MEX Transaction types.

#### 30.4.4.18 MEX Handle

- |          |  |
|----------|--|
| 0        | Use to indicate no Handle. Used to support legacy applications requiring a simply defined PDP context.   |
| 1 to 254 | Valid Handle identifiers.  |
| 255      | Used to indicate failure to generate a valid handle. Only used in confirmation or indication primitives. |

#### 30.4.4.19 MEX IP Request

Used only in "Bypass to SNDCCP" mode.

#### 30.4.4.20 MEX Mode

- Use MEX;
- Bypass to SNDCCP; or
- Deallocate Handle.

#### 30.4.4.21 MEX Modify Report

Where an application is working with "Bypass to SNDTCP" MEX handle, MEX Modify Report shall mimic SNDTCP NSAPI Modify Report (see clause 28.2.3.2):

- Failure (No parameters are changed from their previous values).
- Success Local (One or more of MEX Precedence, PDU Priority, Data Importance, Data Priority have changed from their previous values).
- Success (One or more of the MEX NSAPI QoS parameters were changed from their previous values).
- Full Success (All requested parameter changes have been made).

#### 30.4.4.22 MEX Modify Reject Cause

- Undefined;
- Temporary rejection;
- No response from network;
- Bad response from network;
- NSAPI not activated;
- Requested minimum peak throughput not available;
- Scheduled access not supported;
- Requested schedule not supported;
- Requested QoS not available;
- Secondary PDP contexts not supported;
- Primary PDP context does not exist;
- Asymmetric QoS not supported;
- Automatic QoS filter not supported;
- Specified QoS filter not supported; or
- QoS filter type not supported; or
- QoS filter not available for primary PDP context; or
- SNDTCP service temporarily not available.

#### 30.4.4.23 MEX N-PDU

Any number of bits needed to carry a Network layer protocol PDU. This is typically the full IP packet.

#### 30.4.4.24 MEX NSAPI Usage

- Schedule paused; or
- PDP context paused.

#### 30.4.4.25 MEX PDP Address

- IPv4 address (only when a primary PDP context is being requested); or
- NSAPI (only when a secondary PDP context is being requested).

#### 30.4.4.26 MEX PDP Type

- IPv4 (static address);
- IPv4 (dynamic address negotiation);
- IPv6;
- Mobile IPv4 - Foreign Agent care of address requested;
- Mobile IPv4 - Co-located care of address requested; or
- Primary NSAPI (secondary PDP context requested).

#### 30.4.4.27 MEX Peer IP Filter

An IP address of a network node for which the MS is intended to communicate with.

#### 30.4.4.28 MEX Precedence

See clause 30.2.3.3 for full description of the MEX Precedence.

#### 30.4.4.29 MEX QoS

- A set of:
  - Data Class (see clause 30.2.2.1);
  - Delay Class (see clause 30.2.2.2);
  - Reliability Class (see clause 30.2.2.3);
  - Minimum Peak Throughput (see clause 30.2.3.2);
  - Mean Throughput (see clause 30.2.3.2);
  - Mean Active Throughput (see clause 30.2.3.2);
  - MEX Precedence (see clause 30.2.3.3);
  - Data Priority (see clause 30.2.3.4);
  - PDU Priority (see clause 30.2.3.5);
  - Data Importance (see clause 30.2.3.6);
  - Schedule Repetition Period (see clause 30.2.3.7);
  - Scheduled Number of IP Packets (N-PDUs) per grant (see clause 30.2.3.7);
  - Scheduled IP Packet (N-PDU) size (see clause 30.2.3.7);
  - Schedule Timing Error (see clause 30.2.3.7); and
  - CONTEXT Ready Timer (see clause 30.2.3.8).

### 30.4.4.30 MEX QoS Class

- 0 Identifier of the default QoS settings for a legacy PDP context creation;
- 1 to 8 Identifiers of Specified QoS Class parameters;
- 9 to 32 Identifiers of Manufacturer set Read Only QoS Class parameters; or
- 33 to 255 Identifiers of User writable QoS Class parameters.

### 30.4.4.31 MEX QoS Class Uplink/Downlink Upper/Lower

Values as for MEX QoS Class.

### 30.4.4.32 MEX QoS Class Access

- Read;
- Write;
- Write and Lock;
- Unlock; or
- Locked (Used only in MEX-QOSCLASS Cnf where a MEX QoS Class is locked).

### 30.4.4.33 MEX QoS Filter

- A set of:
  - MEX Filter;
  - MEX Peer IP Filter (optional);
  - MEX Transaction Type; and
  - MEX Filter Type.

### 30.4.4.34 MEX Scheduled Access

- A set of:
  - schedule repetition period;
  - schedule timing error;
  - scheduled number of N-PDUs per grant; and
  - scheduled N-PDU size.

NOTE: The scheduled N PDU size parameter should be repeated as many times as necessary to indicate a size for each scheduled N PDU per grant.

### 30.4.4.35 MEX Transaction Type

- Uplink Filter (Not available when using "Bypass to SNDCCP" mode);
- Downlink Filter;
- Uplink Automatic Filter (Not available when using "Bypass to SNDCCP" mode); or
- Downlink Automatic Filter.

NOTE 1: Uplink Filter and Uplink Automatic Filter are not available when using "Bypass to SNDCCP" mode.

NOTE 2: Uplink Automatic Filter and Downlink Automatic filter are not applicable when MEX Filter Type is "Diffserv".

#### 30.4.4.36 Mobile IPv4 Information

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP Mobile IPv4 Information parameter. See clause 28.1 for a full definition as applied to SN-NSAPI Alloc.

#### 30.4.4.37 NSAPI

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP NSAPI parameter. See clause 28.1 for a full definition as applied to SN-DATA, SN-NSAPI Alloc, SN-NSAPI Configure, SN-NSAPI Dealloc, SN-NSAPI Modify.

#### 30.4.4.38 NSAPI Data Priority

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP NSAPI Data Priority parameter. See clause 28.1 for a full definition as applied to SN-NSAPI Alloc and SN-NSAPI CONFIGURE.

#### 30.4.4.39 NSAPI QoS Negotiation

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP NSAPI QoS Negotiation parameter. See clause 28.1 for a full definition as applied to SN-NSAPI Alloc and SN-NSAPI Modify.

#### 30.4.4.40 PCOMP

This parameter may contain several different protocol compression methods. They may be one or more of: TCP/IP header compression (not available for unacknowledged layer 2 service or real time class data) and IP header compression.

#### 30.4.4.41 PDU Priority

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP PDU Priority parameter. See clause 28.1 for a full definition as applied to SN-DATA and SN-UNITDATA.

#### 30.4.4.42 PDU Priority Max

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP PDU Priority Max parameter. See clause 28.1 for a full definition as applied to SN-NSAPI Alloc.

#### 30.4.4.43 Schelude availability

This parameter indicates availability of scheduled access, see clause 28.3.5.6.

#### 30.4.4.44 Schedule Surplus Flag

This parameter is only used in "Bypass to SNDSCP" mode and mimics the SNDSCP Schedule Surplus Flag parameter. See clause 28.1 for a full definition as applied to SN-DATA and SN-UNITDATA.

---

## Annex A (normative): LLC timers and constants

### A.0 General

This annex lists the LLC timers and constants in the MS.

Where indicated, a value should be chosen by the MS designer from within a given range. For other timers and constants, a default value is given. The default value shall be used by the MS unless it received a different value when it subscribed to that network.

---

### A.1 LLC timers

Timers T.251, T.252, T.261, T.263 and T.265 are defined in terms of downlink signalling frames for the control channel on which the downlink message is expected. When counting downlink signalling frames, the MS should normally count all frames, except that:

- on an assigned channel, the MS shall count only those downlink frames that are available for control signalling on that channel; note, however, that the BS may choose to send a PDU to the MS by stealing from the downlink TCH;
- when the MS transmits using reserved access on a multi-slot channel, if the MS is not frequency full duplex, then, when counting downlink frames, the MS shall count only those frames containing at least one slot that it is able to attempt to receive and decode and that is available for control signalling;
- if the MS is transmitting traffic then:
  - for timer T.251, and if the stealing repeats flag is set for the PDU being sent, the MS shall count all downlink frames (irrespective of whether they are available for control signalling);
  - otherwise, the MS shall count only those downlink frames that it is required to monitor (according to the assigned monitoring pattern(s)) and that are available for control signalling; note, however, that the BS may choose to send a PDU to the MS by stealing from the downlink TCH in one of the monitored slots;

NOTE 1: For a multi-slot channel, if the MS is not frequency full duplex, and if the BS assigns monitoring pattern(s) that the MS is not capable of following, then, when counting downlink frames, the MS counts only those frames containing at least one slot that it is able to monitor and that is available for control signalling.

- if the MS is in minimum mode, the MS shall count only frame 18; note, however, that the BS may choose to send a PDU to the MS in slot 1 during frames 2 to 17;
- on a time-shared MCCH, the MS shall count only frames reserved for this BS; note, however, that the BS may choose to send a PDU to the MS in one of the common frames.

T.251 Sender re-try timer:

- Default value = 4 signalling frames.

T.252 Acknowledgement waiting timer:

- Default value = 9 signalling frames.

T.261 Set-up waiting timer:

- Default value = 4 signalling frames.

T.263 Disconnection waiting timer:

- Default value = 4 signalling frames.

T.265 Reconnection waiting timer:

- Default value = 4 signalling frames.

T.271 Receiver not ready validity timer for the data sending entity:

- Default value = 36 TDMA frames.

NOTE 2: The value of this timer should exceed the value for the data receiving entity T.272.

T.272 Receiver not ready validity timer for the data receiving entity:

- Default value = 18 TDMA frames.

---

## A.2 LLC constants

Constants N.252, N.253, N.262, N.263, N.265, N.273, N.274, N.282 and N.293 define the maximum number of retransmissions or repetitions. The maximum number of transmissions (including the first transmission) is therefore the specified value + 1.

N.251 Maximum length of TL-SDU (basic link):

- This is the maximum length of one TL-SDU if the optional Frame Check Sequence (FCS) is used.
- Default value = 2 595 bits (i.e. approximately 324 octets).
- The FCS is optional. If the FCS is not used, the TL-SDU part may be larger by four octets.

N.252 Maximum number of TL-SDU retransmissions for acknowledged basic link service:

- MS designer choice from range 3 to 5 if the stealing repeats flag is set;
- MS designer choice from range 1 to 5 if the stealing repeats flag is not set.

N.253 Number of TL-SDU repetitions in unacknowledged basic link service:

- MS designer choice from range 0 to 5.

NOTE 1: The service user may indicate the required number of TL-SDU repetitions for a particular TL-SDU in the unacknowledged basic link service. The value of N.253 chosen by the MS designer applies when the service user does not indicate the required number of repetitions.

N.261 Advanced link number:

- This value is defined during the set-up of the advanced link (see AL-SETUP PDU definition). Range: (1; 4).

N.262 Maximum number of connection set-up retries:

- MS designer choice from range 1 to 5.

N.263 Maximum number of disconnection retries:

- MS designer choice from range 3 to 5.

N.264 Number of  $\pi/4$ -DQPSK timeslots used per TDMA frame:

- This value may be defined during the set-up of the advanced link (see AL-SETUP definition). Range: 1 to 4.

N.265 Reconnection retries:

- MS designer choice from range 0 to 5.

N.271 Maximum length of TL-SDU (advanced link):

- This is the maximum length of one TL-SDU including the FCS, it is defined during the set-up of the advanced link (see AL-SETUP PDU definition), Range: (32, 4 096) octets.

N.272 Window size for TL-SDU in acknowledged service:

- This value is defined during the set-up of the advanced link, (see AL-SETUP definition).
  - Range: (1;3) for the original advanced link.
  - Range: (1;15) for an extended advanced link.

N.273 Maximum number of TL-SDU retransmissions:

- This value is defined during the set-up of the advanced link (see AL-SETUP definition). Range: (0;7).

N.274 Maximum number of segment retransmissions:

- This value is defined during the set-up of the advanced link, (see AL-SETUP definition). Range: (0;15).

N.281 Window size for TL-SDU in unacknowledged service:

- This value is defined during the set-up of the advanced link (see AL-SETUP definition).
  - Range: (1;3) for the original advanced link.
  - Range: (1;15) for an extended advanced link.

N.282 Number of repetitions for unacknowledged information:

- This value is defined during the set-up of the advanced link (see AL-SETUP definition). Range: (0;7).

N.293 Number of repetitions of layer 2 signalling PDU:

- MS designer choice from range 0 to 5.

NOTE 2: The MAC may indicate the required number of repetitions of a particular layer 2 signalling PDU. The value of N.293 chosen by the MS designer applies when the MAC does not indicate the required number of repetitions.

NOTE 3: It is recommended that N.293 is set to 0 in most cases.

---

## Annex B (normative): MAC timers and constants

### B.0 General

This annex lists the MAC timers and constants in the MS.

Where indicated, a value should be chosen by the MS designer from within a given range. For other timers and constants, a default value is given. The default value shall be used by the MS unless it received a different value when it subscribed to that network.

---

### B.1 MAC timers

Timers T.202 and T.206 are defined in terms of downlink signalling frames for the control channel on which the downlink message is expected. When counting downlink signalling frames, the MS should normally count all frames, except that:

- on an assigned channel, the MS shall count only those downlink frames that are available for control signalling on that channel; note, however, that the BS may choose to send a PDU to the MS by stealing from the downlink TCH;
- if the MS is transmitting traffic then the MS shall count only those downlink frames that it is required to monitor (according to the assigned monitoring pattern(s)) and that are available for control signalling; note, however, that the BS may choose to send a PDU to the MS by stealing from the downlink TCH in one of the monitored slots;

NOTE 1: For a multi-slot channel, if the MS is not frequency full duplex, and if the BS assigns monitoring pattern(s) that the MS is not capable of following, then, when counting downlink frames, the MS counts only those frames containing at least one slot that it is able to monitor and that is available for control signalling.

- if the MS is in minimum mode, the MS shall count only frame 18; note, however, that the BS may choose to send a PDU to the MS in slot 1 during frames 2 to 17;
- on a time-shared MCCH, the MS shall count only frames reserved for this BS; note, however, that the BS may choose to send a PDU to the MS in one of the common frames.

T.201 Event label inactivity time-out:

- On the MCCH or MCCCH-Q or on a common SCCH, default value = 30 multiframe.
- On any assigned channel, no default upper limit.

T.202 Fragmentation time-out:

- Default value = 9 downlink signalling frames.

T.205 Random access time-out:

- MS designer choice from 5 multiframe to 60 multiframe.

T.206 Reserved access waiting time-out:

- Default value = 18 downlink signalling frames.

NOTE 2: For correct operation of the procedures,  $T.206 \geq T.202$ .

T.208 Inactivity time-out on assigned SCCH:

- Default value = 30 multiframes.

T.209 Inactivity time-out on traffic channel:

- Default value = 18 multiframes.

T.210 Timer for returning to energy economy mode:

- Default value = 18 TDMA frames.

T.211 ACCESS-ASSIGN time-out for transmission of TCH:

- Default value = 36 TDMA frames.

T.212 ACCESS-ASSIGN time-out for reception of TCH:

- Default value = 18 TDMA frames.

T.213 DTX timer:

- Default value = 18 TDMA frames.

T.214 Stealing timer:

- Default value = 6 uplink opportunities.

T.215 Timer for traffic receive authorization if obeying channel allocation after delay:

Default value = 18 TDMA frames.

T.216 Timer for leaving assigned channel after channel replacement:

- Default value = 2 TDMA frames.

T.220 Timer for returning to dual watch reception cycle:

- Default value = 18 TDMA frames.

T.222 Layer 2 data priority lifetime timer:

- This value is defined by SNDCP signalling and given to the MAC in the TMC-CONFIGURE request primitive.

T.223 Layer 2 data priority signalling delay timer:

- This value is defined by SNDCP signalling and given to the MAC in the TMC-CONFIGURE request primitive.

T.226 Napping timer:

- This value is defined in the channel allocation (see channel allocation information element definition).

T.227 Minimum scheduled access waiting time-out:

- Default value = 9 TDMA frames.

T.230 Link adaptation feedback time-out:

- This value is defined when feedback is invited (see L2-LINK-FEEDBACK-CONTROL definition).

T.231 Minimum feedback interval:

- This value may be defined when feedback is invited (see L2-LINK-FEEDBACK-CONTROL definition).
- Otherwise, MS designer choice with  $T.231 \geq 9$  TDMA frames.

T.234 Timer for returning to part-time reception on multi-slot MCCH-Q:

- Default value = 18 TDMA frames.

---

## B.2 MAC constants

N.202 Maximum size of TM-SDU:

- 2 632 bits (i.e. 329 octets).

N.203 Number of timeslots without a fragment before MAC will discard an uncompleted TM-SDU:

- Default value greater than or equal to 4.

N.208 Number of invalid ACCESS-ASSIGN PDUs to leave assigned channel:

- Default value = 3.

NOTE 1: The value of N.208 may be different on a QAM channel from the value on a  $\pi/4$ -DQPSK or D8PSK channel.

N.209 Quality threshold on a QAM channel:

Assumed default value = 4.

NOTE 2: The values of N.209 and N.210 need not be integers.

N.210 Quality threshold on a  $\pi/4$ -DQPSK or D8PSK channel:

- Default value = 4.

N.211 Number of invalid ACCESS-ASSIGN PDUs to stop transmission of TCH:

- Default value = 3.

N.212 Number of invalid ACCESS-ASSIGN PDUs to stop reception of TCH:

- Default value = 3.

N.213 Number of valid ACCESS-ASSIGN PDUs to allow reception of TCH:

- Default value = 3.

N.214 Number of transmissions if stealing repeats flag is set:

- Default value = 4.

N.215 Number of unallocated ACCESS-ASSIGN PDUs to deallocate common channel.

- Default value = 3.

NOTE 3: The value of N.215 may be different on a QAM common channel from the value on a  $\pi/4$ -DQPSK common channel.

N.223 Maximum number of transmissions of same or equivalent L2-DATA-PRIORITY message:

- MS designer choice from range 1 to 5.

N.231 Maximum number of transmissions of same or similar L2-LINK-FEEDBACK-INFO message:

- MS designer choice from range 1 to 5.

---

## Annex C (normative): Mathematical definition of Frame Check Sequence (FCS)

The FCS value corresponding to a given frame is defined by the following procedure:

- 1) the first 4 octets (first 32 bits) of the frame are complemented. If there are less than 32 bits, then those bits will be complemented;
- 2) the  $n$  bits of the frame are then considered to be the co-efficients of a polynomial  $M(x)$  of degree  $n - 1$ ;
- 3)  $M(x)$  is multiplied by  $x^{32}$  and divided by  $G(x)$ , producing a remainder  $R(x)$  of degree less than 32;
- 4) the co-efficients of  $R(x)$  are considered to be a 32-bit sequence;
- 5) the 32-bit sequence is complemented and the result is the FCS.

The generator polynomial is defined as:

$$G(x) = 1 + X + X^2 + X^4 + X^5 + X^7 + X^8 + X^{10} + X^{11} + X^{12} + X^{16} + X^{22} + X^{23} + X^{26} + X^{32} \quad (\text{C.1})$$

NOTE: There is a minor difference in the rule 1 compared to ISO/IEC 13239 [i.8] in the case when the frame length is less than 32 bits.

## Annex D (informative): MAC scenarios for use of traffic channel

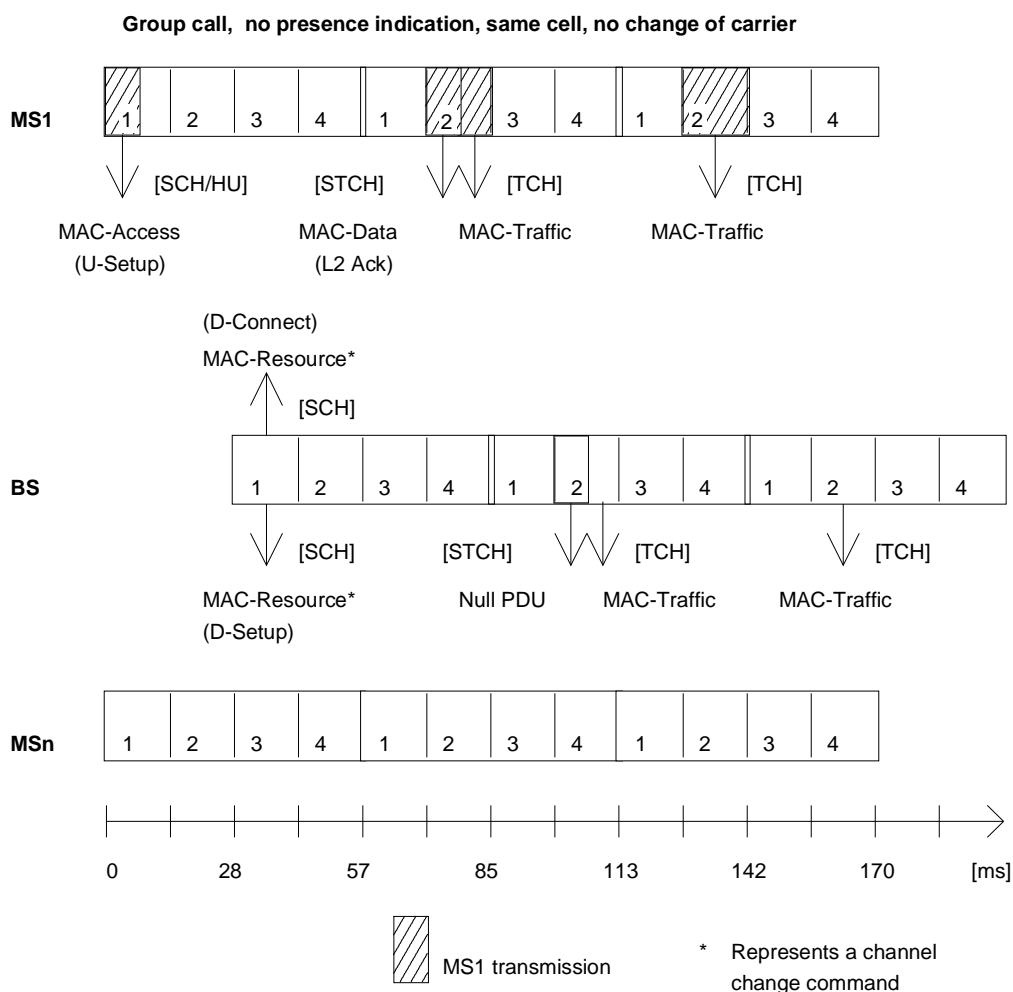

This annex shows some examples of scenarios for use of an assigned channel for a circuit mode call. It demonstrates methods for using the MAC TMD-SAP procedures described in clause 23.8 and shows some possible CMCE signalling scenarios.

The BS may use the protocol facilities provided for call set-up and channel usage for circuit mode calls in many different ways. For example:

- early, medium or late assignment;
- transmission, quasi-transmission or message trunking;
- simplex or duplex calls;
- different strategies in case of transmission errors.

Figure D.1 to figure D.10 illustrate a few examples of signalling related to circuit mode calls. It should be noted that there are many other possible scenarios depending on the BS's methods for allocating resources. It should also be noted that some of the features represented here are optional.

In the figures, \* beside a BS PDU represents a channel change command. In all the examples shown, the position of any slot grant is on the allocated channel.

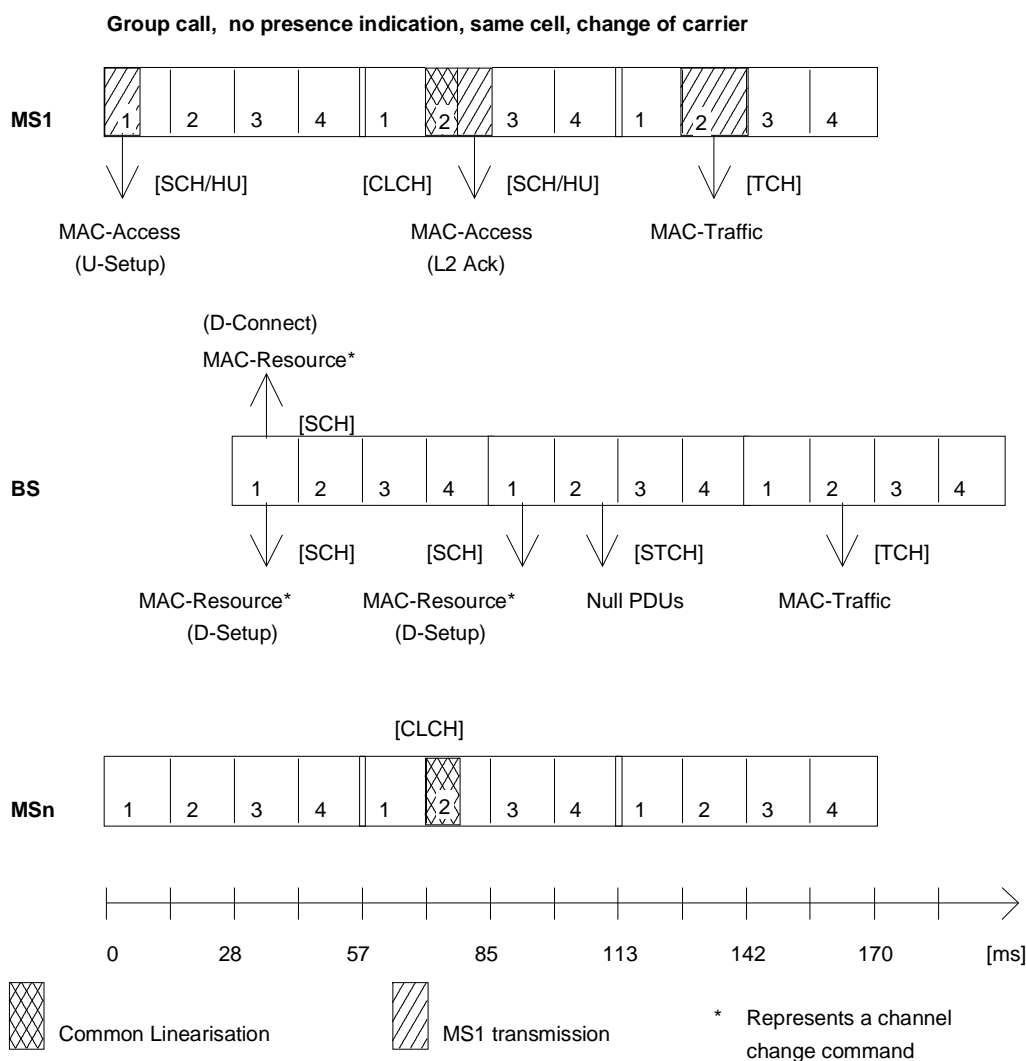

**Figure D.1: Initial access message exchange in group call set-up procedure**

Figure D.1 illustrates a call set-up of a group call on a single CA cell (without presence indication). The assigned channel is on the main carrier, so no CLCH is needed. The D-CONNECT PDU authorizes the calling MS to start transmitting traffic on the assigned channel and the D-SETUP PDU authorizes the called members of the group to receive traffic. In this example, the BS does not grant a subslot for the calling MS's layer 2 acknowledgement to the D-CONNECT PDU, so the MS steals from the first traffic slot. On the downlink, the BS replaces the half slot with the Null PDU on STCH. The BS may send back-up D-SETUP PDUs (not shown) to the called group.

NOTE 1: In this example, the channel assigned for the circuit mode call is on the main carrier. Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels. Therefore this case is not applicable on a DA cell (since the main carrier on a DA cell is a QAM carrier).

In figure D.1, the BS instructs the calling MS to send a layer 2 acknowledgement to the D-CONNECT PDU. This is an optional feature. For example, the BS may choose instead to send the D-CONNECT PDU several times without demanding the layer 2 acknowledgement and so allowing TCH to start one half slot earlier. This general principle applies also to other figures in this annex.

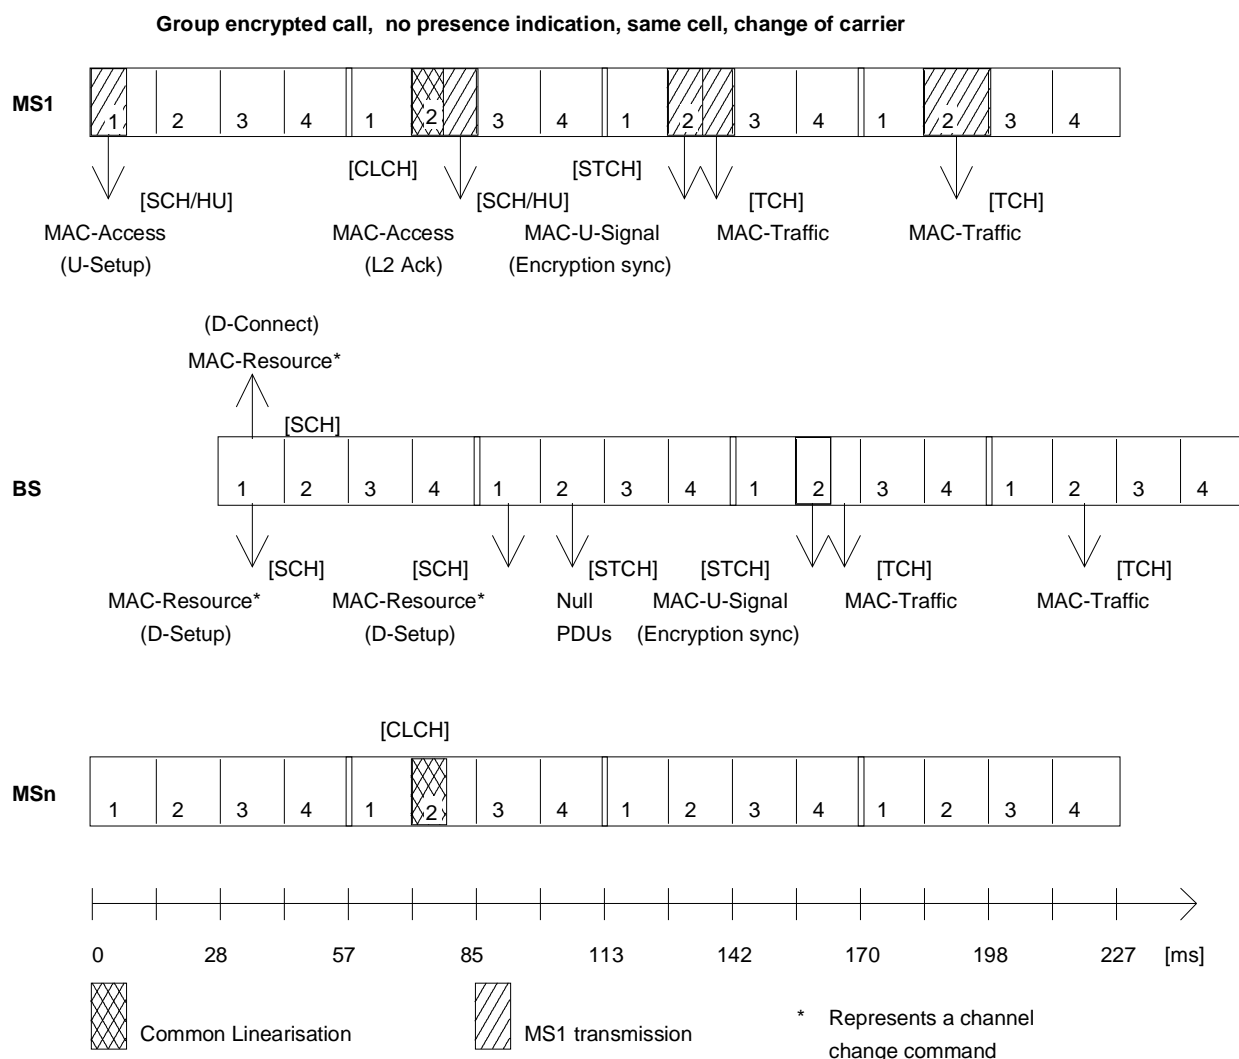

**Figure D.2: Initial access message exchange in group call set-up procedure**

Figure D.2 illustrates another call set-up of a group call on a single CA cell (without presence indication). The assigned channel is not on the main carrier, so the BS gives "Immediate CLCH Permission" to the calling MS with the channel allocation. In this example, the BS grants the second subslot (after the CLCH) for the calling MS's layer 2 acknowledgement; the MS can then start full-slot TCH in the next slot 2. The BS also gives "Immediate CLCH permission" with the first D-SETUP PDU to the group members. In the example, the BS sends a back-up D-SETUP message on the MCCH. There is "No Immediate CLCH Permission" in the back-up message, because the calling MS has already started traffic transmission.

In figure D.2, traffic from the source is not available for transmission in the first downlink slot on the allocated channel. The BS therefore sends C-plane STCH + STCH on the downlink, in this case containing null C-plane signalling, until traffic from the source is available.

NOTE 2: Figures D.2 and D.3 illustrate group call set-up on a CA cell. In these examples, the channel assigned for the circuit mode call is not on the main carrier. Therefore these cases are also generally applicable on a DA cell, except that:

- the U-SETUP PDU exceeds the available capacity within the QAM random access burst (SCH-Q/RA) sent on the DA main carrier, so the calling MS uses fragmentation and the BS needs to grant a subslot (SCH-Q/HU) for the final fragment;
- for a 25 kHz DA main carrier, the BS may prefer to send the D-CONNECT and D-SETUP PDUs in separate slots (e.g. if it wishes to use 4-QAM coding rate = 1/2).

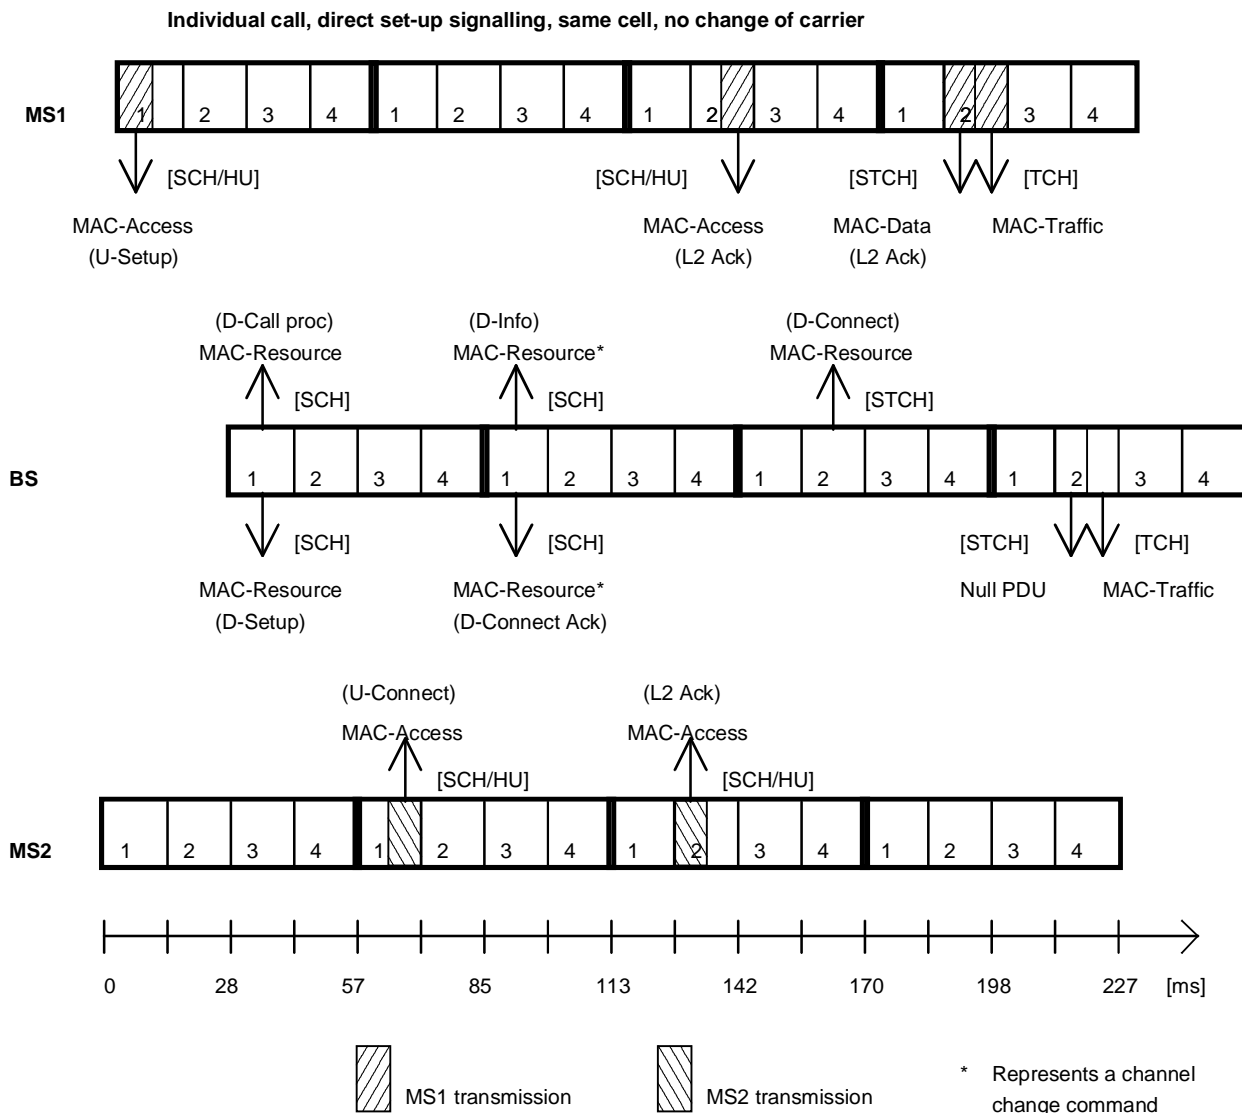

**Figure D.3: End-to-end signalling for starting encryption of speech (group call)**

Figure D.3 is similar to figure D.2 except that this call uses end-to-end encryption, so the calling MS steals from the first traffic slot to send U-plane signalling. This message is passed on to the receiving group.

Figure D.4 illustrates a call set-up of an individual call on a single CA cell (with direct call set-up). The BS checks the availability of the called MS before allocating a traffic channel. The assigned channel is on the main carrier, so no CLCH is needed. In this example, the BS sends D-CONNECT ACK with the channel allocation to the called MS, authorizing it to receive traffic. However, it waits for the called MS to respond before authorizing the calling MS to start transmitting traffic (D-CONNECT PDU).

NOTE 3: In this example, the channel assigned for the circuit mode call is on the main carrier. Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels. Therefore this case is not applicable on a DA cell.

In the example shown, the BS receives a layer 2 acknowledgement from the called MS in the granted subslot. If it had not received a PDU in the granted subslot, then it cannot know whether it was the downlink message that failed or only the uplink response. So it does not know whether the MS is still receiving the MCCH or whether it has moved to slot 2. Using the method illustrated, the BS can repeat the D-CONNECT ACK on the MCCH and also page the MS on slot 2 until it receives a layer 2 acknowledgement on slot 2. The BS can then authorize the calling MS to transmit.

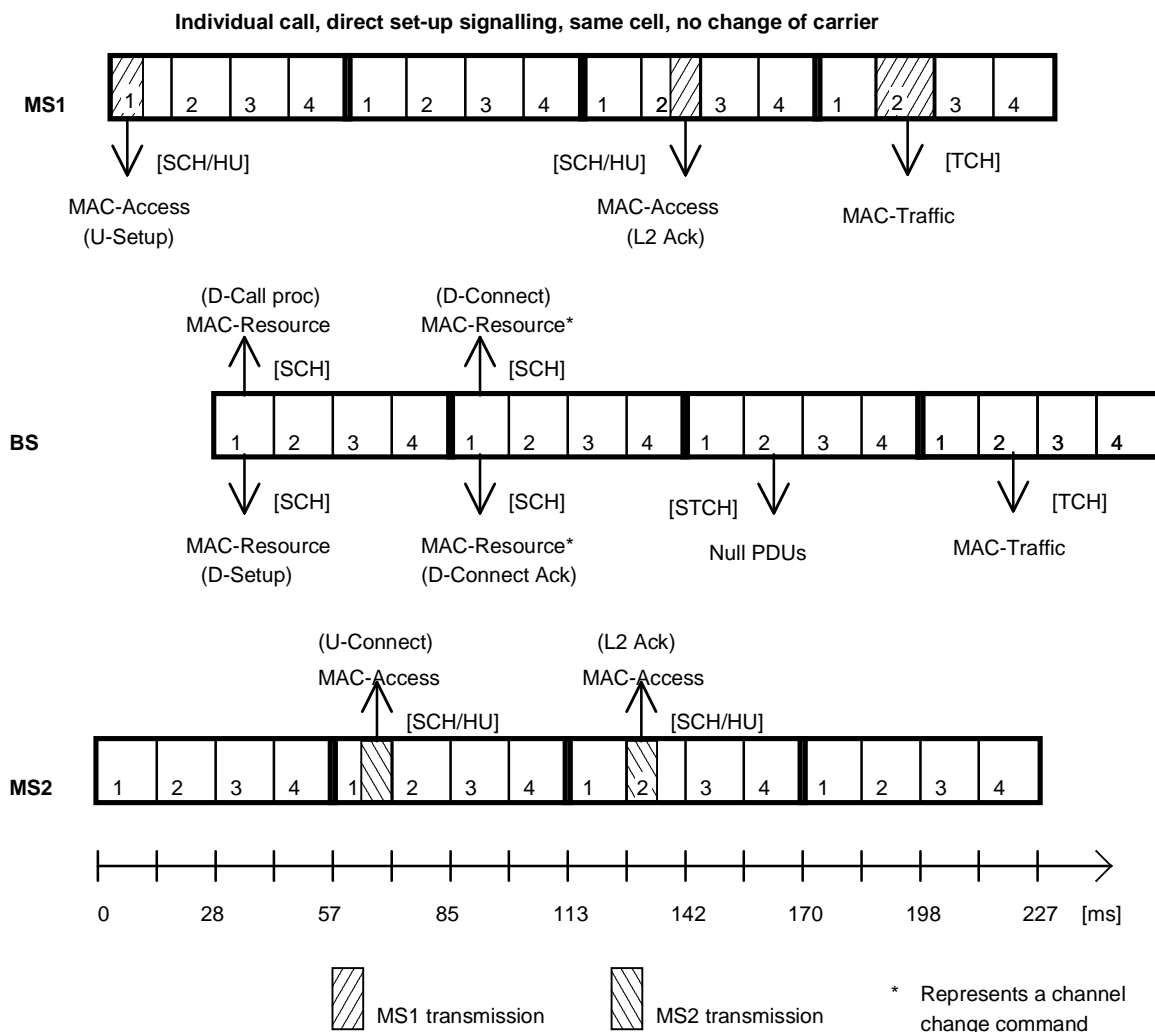

**Figure D.4: Initial access message exchange in individual call set-up procedure**

The signalling method shown in figure D.4 can be used more generally when there may be a queuing delay between D-CALL PROCEEDING and channel allocation. Whereas, in the case illustrated, with no queuing delay, the BS could have delayed the D-CALL PROCEEDING until channel allocation (replacing D-INFO).

Alternatively to the method shown in figure D.4, the BS may send D-CONNECT to the calling MS with the channel allocation (instead of D-INFO). This method is illustrated in figure D.5. It can be seen that this allows TCH to start one half slot earlier. However, if the called MS misses the D-CONNECT ACK PDU, it will not receive the first part of the traffic. Also, for repeat signalling, the BS should either use the unacknowledged service or grant a subslot on the MCCH (i.e. before the channel change) or delay the layer 2 acknowledgement until frame 18.

NOTE 4: In this example, the channel assigned for the circuit mode call is on the main carrier. Circuit mode traffic transmission applies only on  $\pi/4$ -DQPSK channels. Therefore this case is not applicable on a DA cell.

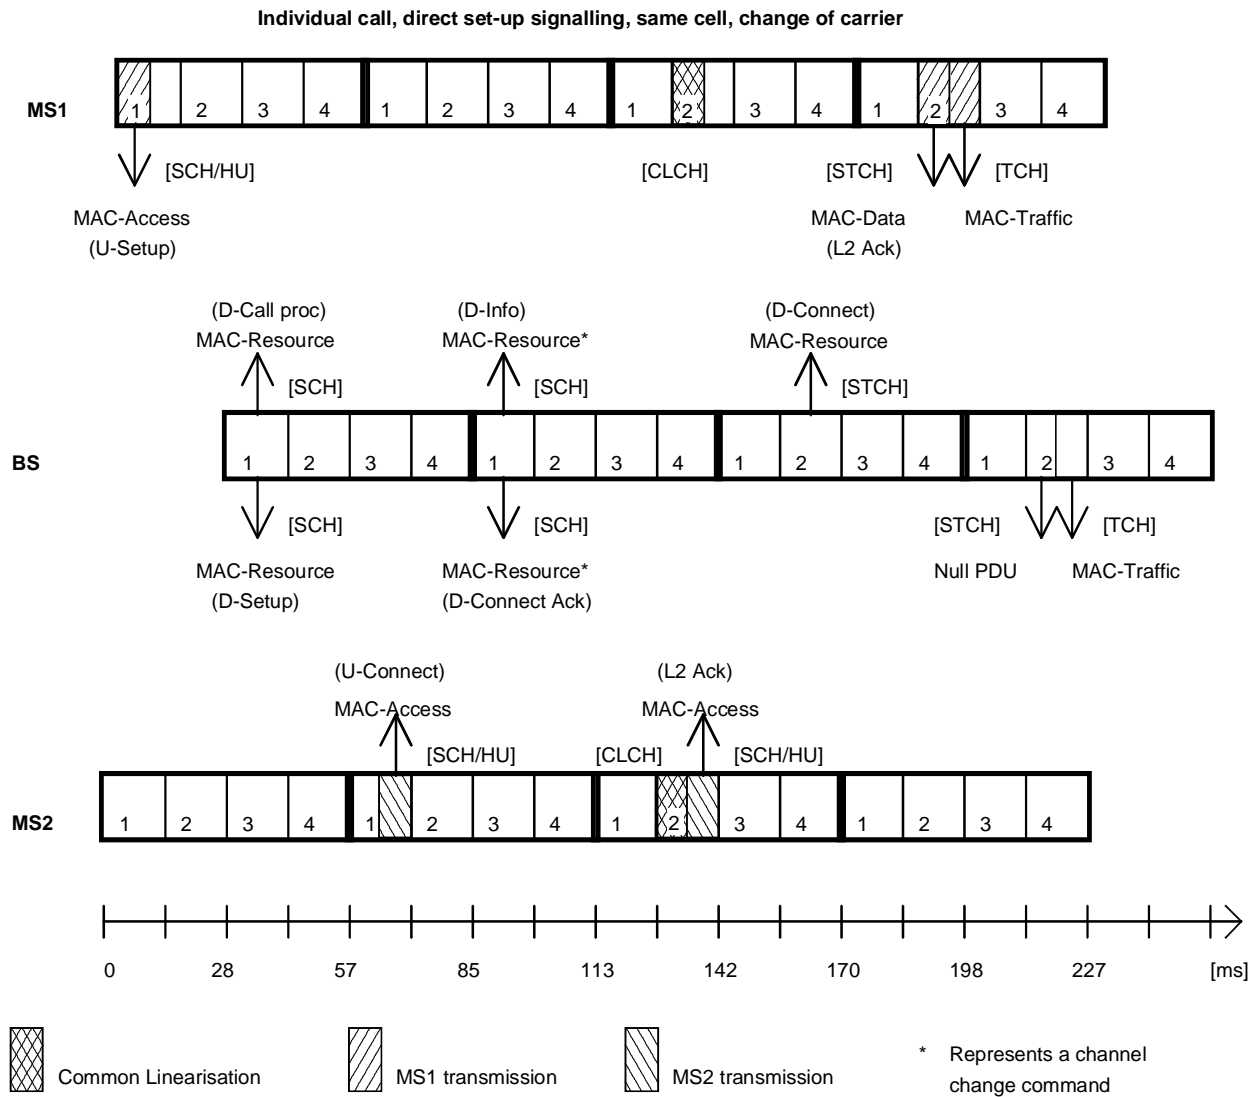

**Figure D.5: Initial access message exchange in individual call set-up procedure**

Figure D.6 is similar to figure D.4, but with a change of carrier.

NOTE 5: Figures D.6 and D.7 illustrate individual call set-up on a CA cell. In these examples, the channel assigned for the circuit mode call is not on the main carrier. Therefore these cases are also generally applicable on a DA cell, except that:

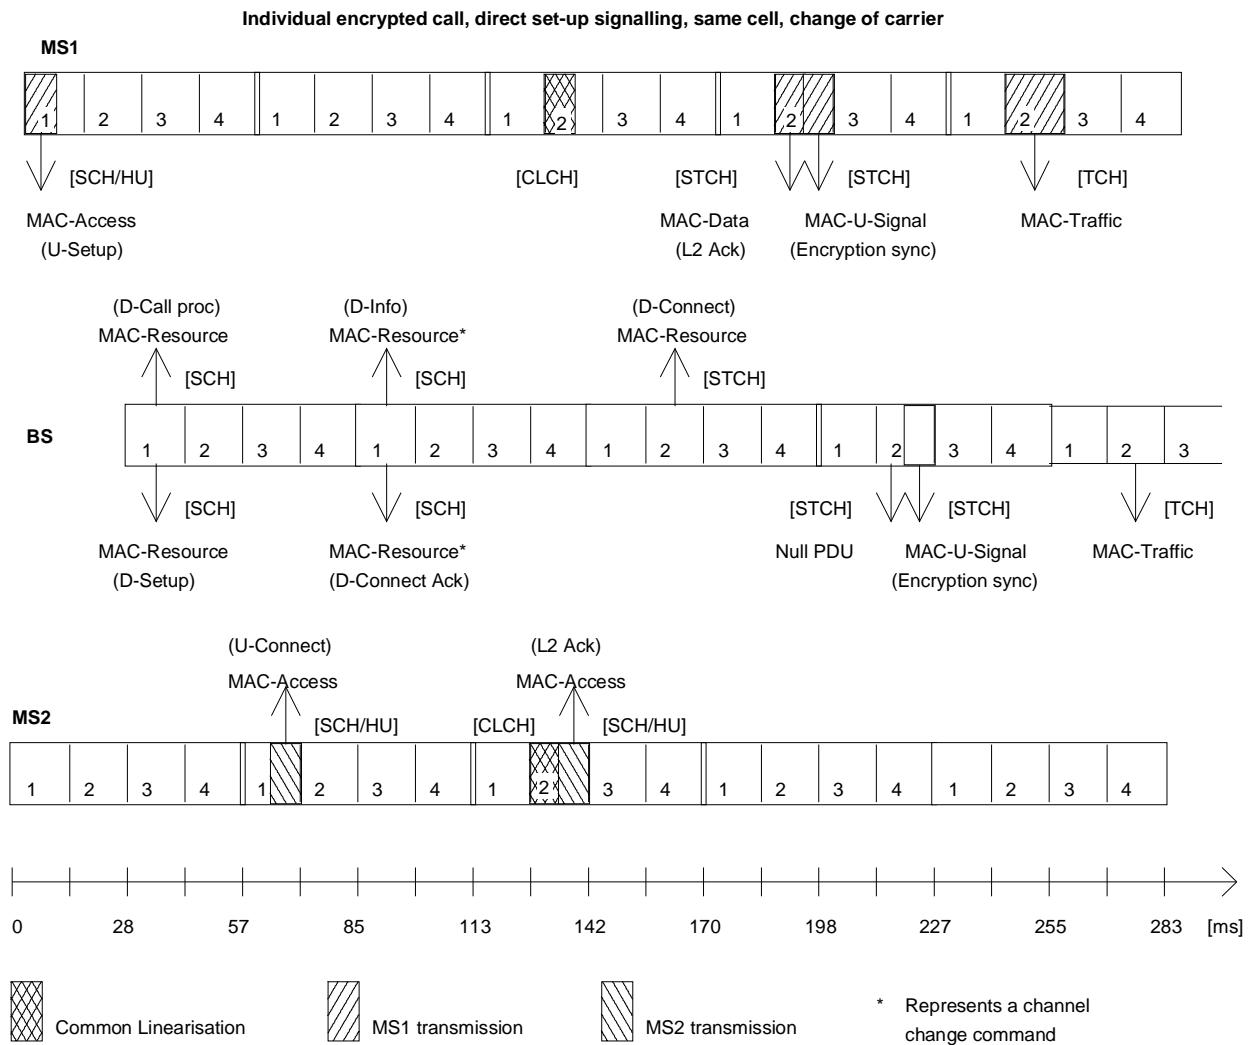

- the U-SETUP PDU exceeds the available capacity within the QAM random access uplink burst (logical channel SCH-Q/RA) sent on the DA main carrier, so the calling MS uses fragmentation and the BS needs to grant a subslot (logical channel SCH-Q/HU) for the final fragment;
- for a 25 kHz DA main carrier, the BS may prefer to grant a full slot (logical channel SCH-Q/U) for the U-CONNECT PDU; for a 50 kHz, 100 kHz or 150 kHz DA main carrier, the U-CONNECT PDU from the called MS can generally be carried in a subslot;
- for a 25 kHz DA main carrier, the BS may prefer to send the downlink PDUs to the calling MS and called MS in separate slots (this may apply particularly if the BS wishes to use 4-QAM coding rate = 1/2 when it is sending the D-INFO and D-CONNECT ACK PDUs).

**Figure D.6: Initial access message exchange in individual call set-up procedure**

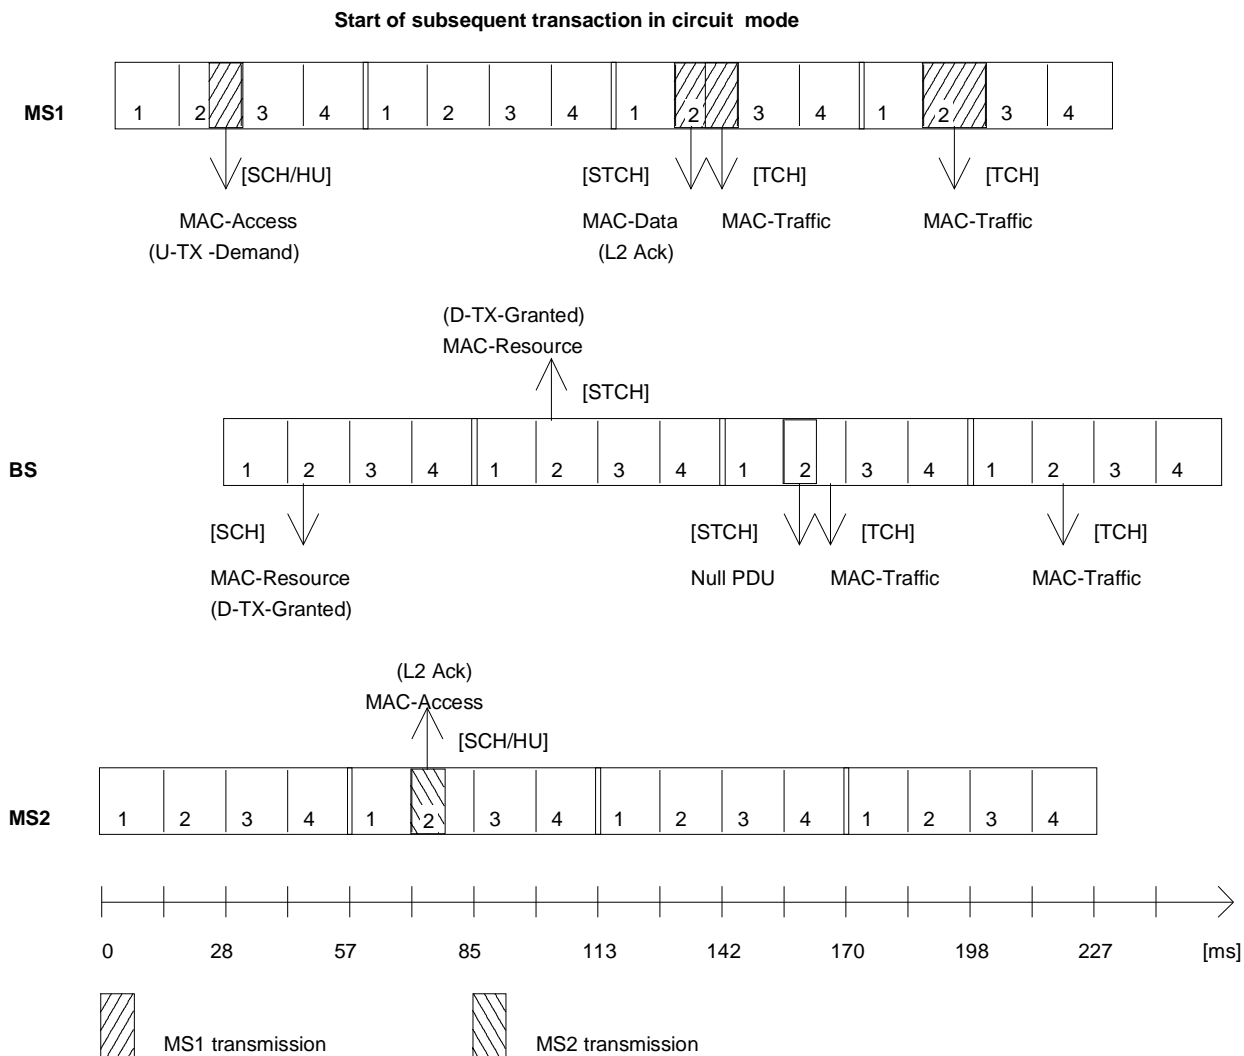

Figure D.7 is similar to figure D.6, except that this call uses end-to-end encryption.

**Figure D.7: End-to-end signalling for starting encryption of speech (individual call)**

Figures D.9 and D.10 show options for signalling at the start of subsequent "over" for a message trunked call. The BS may prefer to wait for an acknowledgement from the receiving party before giving transmit permission, as in figure D.9. Or it may give transmit and receive permission at the same time, as in figure D.10 (risking some loss of traffic by the recipient).

**Figure D.9: Start of subsequent transaction in circuit mode**

**Figure D.10: Start of subsequent transaction in circuit mode**

## Annex E (normative): PDU encoding rules and examples

### E.0 General

This annex defines general PDU encoding rules and examples for some PDUs, which may require further clarification.

### E.1 PDU encoding rules for CMCE, MM and SNDCP PDUs

#### E.1.1 General PDU encoding rules for CMCE, MM and SNDCP PDUs

The general format of the PDUs are defined in table E.1. The information element Protocol identifier is present for each PDU before the PDU type element although not shown in the PDU descriptions. The MLE sub-layer shall add/remove Protocol identifier element before sending the PDU to lower layers or passing the PDU to other layer 3 entities.

The elements shall be transmitted in the order specified by the table with the top element being transmitted first (before interleaving). The content of an information element is represented by a binary value and the most significant bit of that binary value shall be transmitted first (before interleaving).

**Table E.1: CMCE, MM and SNDCP PDU layout**

| Information element                     | Length   | Value | Remark   |
|---|----------|-------|--|
| PDU type                                | variable |       | Dependent on the protocol entity               |
| Type 1 element (1)                      | variable |       | See definitions below                          |
| Type 1 element (2)                      | variable |       | See definitions below                          |
| etc.                                    | etc.     |       | Etc.   |
| Type 1 element (m)                      | variable |       | See definitions below                          |
| Conditional element to previous element | variable |       | See definitions below                          |
| etc.                                    | etc.     |       | Etc.   |
| Type 1 element (m+1)                    | variable |       | See definitions below                          |
| etc.                                    | etc.     |       | Etc.   |
| Type 1 element (n)                      | variable |       | See definitions below                          |
| Optional bit (O-bit)                    | 1        | 0     | No optional type 2 or type 3/4 elements follow |
|   |          | 1     | Optional type 2 or type 3/4 elements follow    |
| Presence bit (P-bit) (1)                | 1        | 0     | The type 2 element (1) is not present          |
|   |          | 1     | The type 2 element (1) is present              |
| Type 2 element (1)                      | variable |       | See definitions below                          |

| Type 3 element identifier (n)   | 4        |            | See definitions below   |
| Length indicator (n)            | 11       |            | See length indicator (1)  |
| Type 3 element (n)              | variable |            | See definitions below   |
| More bit (M-bit) (n+1) = 0      | 1        | 0          | Last M-bit (Least Significant Bit (LSB) in the PDU) = 0   |

#### Presence of O-bit, P-bit and M-bit:

The O-bit is always present straight after last type 1 element or element conditional to the last type 1 element unless stated otherwise in the PDU description. In case O-bit has value "0", the PDU contains no more elements; no P-bits for type 2 elements, no type 2 elements, no M-bits nor type 3 or type 4 elements.

In case the O-bit has value 1, then at least one type 2, type 3 or type 4 element follows. In this case there is P-bit for each type 2 element which is defined for the PDU; if the type 2 element is present in the PDU then the corresponding P-bit has value 1, if the type 2 element is not present, then the corresponding P-bit has value 0.

NOTE 1: There is no P-bit before an element that is conditional to type 2 element.

In case the O-bit has value 1, then after the last type 2 element or element that is conditional to the last type 2 element, or after the P-bit indicating that the last type 2 element is not present, there is always an M-bit telling whether there are any type 3 or type 4 elements present in the PDU. For each type 3 or type 4 element present in the PDU there is preceding M-bit having value 1. After the last type 3 or type 4 element, there is always one M-bit (the last bit in the PDU) having value 0.

NOTE 2: If there are type 2 element(s) present in the PDU and no type 3/4 elements are specified for the PDU, the M bit is present and set to "0" unless stated otherwise in the PDU description.

NOTE 3: In case the PDU definition does not contain any type 2 elements and the PDU contains type 3 or type 4 elements, then there is the O-bit having value 1 after the last type 1 element or element conditional to the last type 1 element, followed by M-bit having value 1 and then the first type 3 or type 4 element.

NOTE 4: If there is no type 2 nor type 3 nor type 4 elements specified for the PDU the O-bit is present and set to "0" unless stated otherwise in the PDU description.

#### Length of the elements:

The length of a type 1 or type 2 element or element conditional to type 1 or type 2 element is either fixed as indicated in the "Length" column in the PDU or the length may be indicated by the value of a preceding element to which this element is conditional, or it shall be possible for the receiver to determine the length of the element by the examination of the element and its sub-elements.

NOTE 5: A conditional element may also be present in the PDU varying times as indicated by the value of a preceding element to which this element is conditional. In such case the element is marked as "Repeatable" in the PDU.

The length of a type 3 and type 4 element is indicated by the preceding "Length indicator" element.

NOTE 6: Because of these PDU encoding rules, only adding of a type 3 or type 4 element can be done without causing backward incompatibility problems, as the decoding entity can pass unknown type 3 and type 4 elements because their length is indicated in the PDU whereas the length of type 1 or type 2 element are known beforehand.

#### Encoding rules for PDU:

The element type defines the encoding rule applied to an element as follows:

- Type 1 elements are mandatory and shall be placed within the PDU in a fixed order as specified in the PDU description tables. Type 1 elements shall be placed before any type 2 or type 3 elements in the PDU encoding. In addition the PDU may contain elements that are conditional to type 1 elements; they are present only if the corresponding type 1 element has specified value. These conditional elements are placed after the type 1 elements to which they are conditional;
- Type 2 elements are optional and shall be placed within the PDU in a fixed order as specified in the PDU description tables. Type 2 elements shall be placed after all type 1 elements and elements conditional to type 1 elements, and before any type 3 elements in the PDU encoding. In addition the PDU may contain elements that are conditional to type 2 elements; they are present only if the corresponding type 2 element has specified value. These conditional elements are placed after the type 2 elements to which they are conditional;
- Type 3 and type 4 elements are optional and shall be placed within the PDU in numerical order as specified within the "type 3/4 Element Identifier" element. Type 3/4 Elements shall be placed after any type 1 and type 2 elements in the PDU encoding. Each type 3 and type 4 element shall be preceded by a "type 3/4 Element Identifier" element and a "Length Indicator" element in that order. In addition for each type 4 element a length indicator shall be followed by the "Number of repeated elements" information element.

NOTE 7: For presentation purposes a set of information elements can be defined as an information element. The set of information sub-elements may contain also optional or conditional elements and also elements consisting of set of sub-elements. The set is encoded into the PDU as if it were a single information element of the indicated type.

The following rules shall apply for decoding of the PDU:

```

DO for all Type 1 elements
  DECODE Type 1 element
    WHILE conditional elements to the type 1 element
      DECODE conditional element
    END WHILE
END DO
DECODE O-bit
IF O-bit set to 'No Optional Elements present'
  THEN END of PDU decoding
ELSE
  DO for all possible Type 2 elements
    DECODE P-bit
    IF P-bit set to 'Present'
      THEN DECODE Type 2 element AND
        WHILE conditional elements to the type 2 element
          DECODE conditional element
        END WHILE
    END DO
  WHILE M-bit set to 'More Type 3/4 elements follows'
    IF element is a Type 4 element
      THEN DECODE Number of repeated elements
        WHILE more type 4 sub-elements
          DECODE Type 4 sub-element
        END WHILE
    ELSE
      DECODE Type 3 element
    END IF
  END WHILE
END of PDU decoding.

```

The encoding rules for elements and sub-elements:

- in case the PDU information element or sub-element definition contains no "Type" column, the sub-elements of the element/sub-element shall be all considered to be of type 1;
- type 1 element or type 1 sub-element can contain only type 1 or type 2 sub-elements and conditional elements to type 1 or type 2 element/sub-element;
- type 2 element or type 2 sub-element can contain only type 1 or type 2 sub-elements and conditional elements to type 1 or type 2 element/sub-element;
- element conditional to type 1 or type 2 element or sub-element can contain only type 1 or type 2 sub-elements and conditional elements to type 1 or type 2 element/sub-element;
- in case the type 1 element definition does not contain optional sub-elements, there is no O-bit after the type 1 sub-elements;
- in case the type 1 element definition contains optional sub-elements, there shall be an O-bit after the last type 1 sub-element. There shall be no M-bit after the last type 2 element or conditional element or the P-bit indicating that the last type 2 element is not present;
- type 3 or type 4 element or sub-element can contain sub-elements which can be one of type 1, 2, 3 and 4. In case the type 3 or type 4 element/sub-element definition does not contain optional elements, there is no O-bit after the type 1 sub-elements;

NOTE 8: Any supplementary service PDU may contain optional type 3/4 information elements unless the supplementary service PDU definition states otherwise. For that purpose those supplementary service PDUs contain O-bit as the last bit also when all the PDU information elements are of type 1 independent of whether it is carried in a facility information element or in U/D-FACILITY PDU, refer to clause E.1.2 for examples.

- in case type 3 or type 4 element/sub-element definition contains optional type 2 or type 3 elements, there shall be an O-bit indicating whether the type 3/4 element/sub-element contains any optional elements:
  - in case the type 3 or type 4 element/sub-element contains no optional elements, the O-bit is set to value "no optional elements follow" and no other information shall be included to the type 3 or type 4 element/sub-element;

- in case the type 3 or type 4 element/sub-element contains optional elements (either type 2 or type 3 or type 4) the O-bit is set to value "optional elements follow" and a P-bit shall be set for each type 2 optional element (if any defined) indicating presence of that element. The P-bit shall indicate either "type 2 element present" or "type 2 element not present":
  - in case the element/sub-element definition does not contain any type 3 or type 4 elements there shall be no M-bit after the last type 2 element or conditional element or the P-bit indicating that the last type 2 element is not present;
  - in case the type 3/4 element/sub-element definition contains type 3/4 elements, there shall be a M-bit after the last type 2 element or conditional element or P-bit indicating that last optional type 2 element is not present, indicating whether the element/sub-element contains any type 3/4 elements. The type 3 and type 4 sub-elements are coded similarly as type 3 and type 4 PDU information elements, i.e. type 3 and type 4 sub-element shall be preceded by a "type 3/4 Element Identifier" element and a "Length Indicator" element in that order. In addition in the type 4 sub-element a length indicator shall be followed by the "Number of repeated elements" information element. A further M-bit shall follow each Type 3/4 sub-element to indicate either "type 3/4 element to follow" or "no type 3/4 element to follow". After the last type 3/4 sub-element included the M-bit shall be set to "0" to indicate "no type 3/4 element to follow" in this sub-element:
    - in case the information element/sub-element contains one or more type 3 elements but no type 2 elements are specified for the element/sub-element, an M-bit (having value "type 3/4 elements to follow") shall follow the O-bit (having value "optional elements to follow") placed after the last type 1 element;
    - in case the element/sub-element contains no type 3/4 elements but contains type 2 elements there shall be one M-bit bit indicating "no type 3/4 elements to follow" after the last type 2 element or P-bit indicating that last optional type 2 element is not present as the last bit in the type 3/4 element.

The C/O/M column indicates how the presence of an information element is controlled in the PDU or element/sub-element:

- M: Mandatory information element is always present (mandatory) in the main PDU level and is always present in a sub-element, when the sub-element itself is present. The type of mandatory element is type 1;
- O: Optional information element may be present in the PDU. The protocol state or an implementation choice defines when it is present or not. The type of optional element is either type 2 or type 3 or type 4;
- C: Conditional information element is present as defined in the PDU or element/sub-element description. The presence depends on the value of another preceding information element. If the information element on which the conditional information element is conditional is not present then also the conditional information element is not present. The conditional information element may be also repeated as many times as indicated by a preceding information element.

## E.1.2 PDU encoding examples for CMCE PDUs

Tables E.2 to E.8 present examples of proper CMCE PDU encoding in specific cases.

**Table E.2: D-FACILITY PDU with two SS-PDUs**

| Information Element   | Length   | Type  | C/O/M | Value                                |
|---|----------|-------|-------|--------------------------------------|
| Protocol discriminator  | 3        | 1     | M     | CMCE                                 |
| PDU Type  | 5        | 1     | M     | D-FACILITY                           |
| Number of SS PDUs   | 4        | 1     | M     | 2                                    |
| Length indicator  | 11       | 1     | M     | variable                             |
| SS-PDU contents   | variable | 1     | C     | variable                             |
| Length indicator  | 11       | 1     | M     | variable                             |
| SS-PDU contents   | variable | 1     | C     | variable                             |
| Optional elements present?  | 1        | O-bit |       | 0 ("not present" for D-FACILITY PDU) |
| NOTE: When the U/D-FACILITY PDU contains more than a single SS-PDU it is a collection of SS-PDUs which are encoded independently of each other. Each SS-PDU may contain any type of information elements as defined for the SS-PDU. |          |       |       |                                      |

**Table E.3: D-FACILITY PDU with "SS not supported" acknowledgement**

| Information Element        | Length | Type  | C/O/M | Value                                      |
|----------------------------|--------|-------|-------|--|
| Protocol discriminator     | 3      | 1     | M     | CMCE                                       |
| PDU Type                   | 5      | 1     | M     | D-FACILITY                                 |
| Number of SS PDUs          | 4      | 1     | M     | 1  |
| Length indicator           | 11     | 1     | M     | 12   |
| SS-PDU contents            | 12     |       |       | <i>See next 3 elements</i>                 |
| SS-Type                    | 6      | 1     | M     | SS-DGNA                                    |
| SS-PDU Type                | 5      | 1     | M     | SS not supported                           |
| Optional elements present? | 1      | O-bit |       | 0 ("not present" for SS not supported PDU) |
| Optional elements present? | 1      | O-bit |       | 0 ("not present" for D-FACILITY PDU)       |

Table E.4: D-FACILITY with SS-DGNA ASSIGN PDU

| Information Element  | Length     | Type  | C/O/M | Value                                       |
|--|------------|-------|-------|---|
| Protocol discriminator   | 3          | 1     | M     | CMCE  |
| PDU Type   | 5          | 1     | M     | D-FACILITY                                  |
| Number of SS PDUs  | 4          | 1     | M     | 1   |
| Length indicator   | 11         | 1     | M     | 147   |
| <i>SS-PDU contents</i>   | <i>147</i> |       |       | <i>See next 20 rows</i>                     |
| SS type  | 6          | 1     | M     | SS-DGNA                                     |
| SS-DGNA PDU type   | 5          | 1     | M     | ASSIGN                                      |
| Number of groups   | 5          | 1     | M     | 2 (Group assignments)                       |
| <i>Group assignment (first)</i>  | <i>82</i>  |       |       | <i>See next 15 rows</i>                     |
| 1 Group SSI  | 24         | 1     | M     | Any   |
| Group extension present  | 1          | 1     | M     | Group extension present                     |
| Group extension  | 24         |       | C     | Any   |
| Group identity attachment mode   | 3          | 1     | M     | Any   |
| Optional elements present?   | 1          | O-bit |       | 1 (present)                                 |
| P-bit for Class of usage element   | 1          | P-bit |       | 1 (present)                                 |
| Class of usage   | 3          | 2     | O     | Any   |
| P-bit for Mnemonic group name element  | 1          | P-bit |       | 1 (present)                                 |
| Mnemonic group name  | 39         |       |       | <i>See next three elements.</i>             |
| Text coding scheme   | 7          | 1     | M     | Latin-1 (8-bit characters)                  |
| Length of mnemonic group name character string   | 8          | 1     | M     | 24  |
| Mnemonic group name character string   | 24         |       | C     | "EPT" (= 3 × 8)                             |
| P-bit for Length of security related information element   | 1          | P-bit |       | 0 (not present)                             |
| Length of additional group information element   | 1          | P-bit |       | 0 (not present)                             |
| P-bit for (V)GSSI  | 1          | P-bit |       | 0 (not present)                             |
| <i>Group assignment (second)</i>   | <i>29</i>  |       |       | <i>See next 4 rows</i>                      |
| 2 Group SSI  | 24         | 1     | M     | Any   |
| Group extension present  | 1          | 1     | M     | 0 (not present)                             |
| Group identity attachment mode   | 3          | 1     | M     | Any   |
| Optional elements present?   | 1          | O-bit |       | 0 ("not present" for this Group assignment) |
| Acknowledgement requested from affected user(s)  | 1          | 1     | M     | Any   |
| Optional elements present?   | 1          | O-bit |       | 0 ("not present" for SS-DGNA ASSIGN PDU)    |
| Optional elements present?   | 1          | O-bit |       | 0 ("not present" for D-FACILITY PDU)        |
| NOTE: The Mnemonic name encoding requires that the receiving entity is capable to understand the Length of mnemonic group name character string information element. The decoding of the mnemonic name is optional as the length allows to by-pass the name. |            |       |       |   |

Table E.5: U-INFO PDU with DTMF element

| Information Element           | Length | Type  | C/O/M | Value           |
|-------------------------------|--------|-------|-------|-----------------|
| Protocol discriminator        | 3      | 1     | M     | CMCE            |
| PDU Type                      | 5      | 1     | M     | U-INFO          |
| Poll response                 | 1      | 1     | M     | 0               |
| Optional elements present?    | 1      | O-bit |       | 1 (present)     |
| P-bit for Modify element      | 1      | P-bit |       | 0               |
| Type 3 / 4 elements to follow | 1      | M-bit |       | 1 (present)     |
| Type 3/4 element identifier   | 4      | 1     | M     | DTMF            |
| Length indicator              | 11     | 1     | M     | 11              |
| DTMF type                     | 3      | 1     | M     | DTMF tone start |
| DTMF digit                    | 4      | 1     | M     | 1st digit       |
| DTMF digit                    | 4      | 1     | M     | 2nd digit       |
| Type 3/4 elements to follow   | 1      | M-bit |       | 0 (not present) |

Table E.6: U-STATUS PDU with External subscriber number element

| Information Element               | Length | Type  | C/O/M | Value                      |
|-----------------------------------|--------|-------|-------|----------------------------|
| Protocol discriminator            | 3      | 1     | M     | CMCE                       |
| PDU Type                          | 5      | 1     | M     | U-STATUS                   |
| Area selection                    | 4      | 1     | M     | Any                        |
| Called party type identifier      | 2      | 1     | M     | SSI                        |
| Called party SSI                  | 24     |       | C     | Any gateway                |
| Pre-coded status                  | 16     | 1     | M     | Any                        |
| Optional elements present?        | 1      | O-bit |       | 1 (present)                |
| Type 3/4 elements to follow       | 1      | M-bit |       | 1 (present)                |
| Type 3/4 element identifier       | 4      | 1     | M     | External subscriber number |
| Length indicator                  | 11     | 1     | M     | 28                         |
| <i>External subscriber number</i> | 28     |       |       | <i>See next seven rows</i> |
| External subscriber number digit  | 4      | 1     | M     | 1st digit                  |
| External subscriber number digit  | 4      | 1     | M     | 2nd digit                  |
| External subscriber number digit  | 4      | 1     | M     | 3rd digit                  |
| External subscriber number digit  | 4      | 1     | M     | 4th digit                  |
| External subscriber number digit  | 4      | 1     | M     | 5th digit                  |
| External subscriber number digit  | 4      | 1     | M     | 6th digit                  |
| External subscriber number digit  | 4      | 1     | M     | 7th digit                  |
| Type 3/4 elements to follow       | 1      | M-bit |       | 0 (not present)            |

Table E.7: U-SETUP with SS-AL INVOKE1 PDU

| Information Element           | Length | Type  | C/O/M | Value                             |
|-------------------------------|--------|-------|-------|-----------------------------------|
| Protocol discriminator        | 3      | 1     | M     | CMCE                              |
| PDU Type                      | 5      | 1     | M     | U-SETUP                           |
| Area selection                | 4      | 1     | M     | Any                               |
| Hook method selection         | 1      | 1     | M     | 0                                 |
| Simplex/duplex selection      | 1      | 1     | M     | 0                                 |
| Basic service information     | 8      | 1     | M     | 0                                 |
| Request to transmit/send data | 1      | 1     | M     | 0                                 |
| Call priority                 | 4      | 1     | M     | Any                               |
| CLIR control                  | 2      | 1     | M     | Any                               |
| Called party type identifier  | 1      | 1     | M     | SSI                               |
| Called party SSI              | 24     |       | C     | Any                               |
| Optional elements present?    | 1      | O-bit |       | 1 (present)                       |
| Type 3/4 elements to follow   | 1      | M-bit |       | 1 (present)                       |
| Type 3 element identifier     | 4      | 1     | M     | Facility                          |
| Length indicator              | 11     | 1     | M     | 12                                |
| <i>SS-PDU contents</i>        | 12     |       |       | <i>See next 3 rows</i>            |

| Optional elements present?      | 1      | O-bit |       | 0 ("not present" for INVOKE1 ACK PDU) |
| More optional elements present? | 1      | M-bit |       | 0 ("not present" for D-CONNECT PDU)   |

### E.1.3 PDU encoding examples for MM PDUs

Tables E.9 to E.14 present examples of proper MM PDU encoding in specific cases.

**Table E.9: D-ATTACH/DETACH GROUP IDENTITY PDU**

| Information Element                            | Length | Type  | C/O/M | Value                            |
|--|--------|-------|-------|----------------------------------|
| Protocol discriminator                         | 3      | 1     | M     | MM                               |
| PDU Type                                       | 4      | 1     | M     | D-ATTACH / DETACH GROUP IDENTITY |
| Group identity report                          | 1      | 1     | M     | No report request                |
| Group identity acknowledgement request         | 1      | 1     | M     | Any                              |
| Group identity attach/detach mode              | 1      | 1     | M     | Any                              |
| Optional elements present?                     | 1      | O-bit |       | 1                                |
| Type 3 / 4 elements to follow                  | 1      | M-bit |       | 1                                |
| Type 3/4 element identifier                    | 4      | 1     | M     | Group identity downlink          |
| Length indicator                               | 11     | 1     | M     | 67                               |
| Number of repeated elements                    | 6      | 1     | M     | 2                                |
| 1 Group identity attach/detach type identifier | 1      | 1     | M     | Attachment                       |
| Group identity attachment                      | 5      |       | C     | See next 2 rows                  |
| Group identity attachment lifetime             | 2      | 1     | M     | Any                              |
| Class of usage                                 | 3      | 1     | M     | Any                              |
| Group identity address type                    | 2      | 1     | M     | GSSI                             |
| GSSI   | 24     |       | C     | Any                              |
| 2 Group identity attach/detach type identifier | 1      | 1     | M     | Detachment                       |
| Group identity detachment downlink             | 2      |       | C     | Any                              |
| Group identity address type                    | 2      | 1     | M     | GSSI                             |
| GSSI   | 24     |       | C     | Any                              |
| Type 3/4 elements to follow?                   | 1      | M-bit |       | 0                                |

**Table E.10: D-LOCATION UPDATE ACCEPT PDU without optional elements**

| Information Element         | Length | Type  | C/O/M | Value                    |
|-----------------------------|--------|-------|-------|--------------------------|
| Protocol discriminator      | 3      | 1     | M     | MM                       |
| PDU Type                    | 4      | 1     | M     | D-LOCATION UPDATE ACCEPT |
| Location update accept type | 3      | 1     | M     | Any                      |
| Optional elements present?  | 1      | O-bit |       | 0                        |

Table E.11: D-LOCATION UPDATE ACCEPT PDU with optional Type 4 elements

| Information Element   | Length | Type  | C/O/M | Value  |
|---|--------|-------|-------|--|
| Protocol discriminator  | 3      | 1     | M     | MM   |
| PDU Type  | 4      | 1     | M     | D-LOCATION UPDATE ACCEPT   |
| Location update accept type                                       | 3      | 1     | M     | Any  |
| Optional elements present?  | 1      | O-bit |       | 1  |
| P-bit for SSI element   | 1      | P-bit |       | 0  |
| P-bit for Address extension element                               | 1      | P-bit |       | 0  |
| P-bit for Subscriber class element                                | 1      | P-bit |       | 1  |
| Subscriber class  | 16     | 2     | O     | Any  |
| P-bit for Energy saving information element                       | 1      | P-bit |       | 0  |
| P-bit for SCCH information and distribution on 18th frame element | 1      | P-bit |       | 0  |
| Type 3 / 4 elements to follow                                     | 1      | M-bit |       | 1  |
| Type 3/4 element identifier                                       | 4      | 1     | M     | New registered area  |
| Length indicator  | 11     | 1     | M     | 42   |
| Number of repeated elements                                       | 6      | 1     | M     | 2  |
| 1 LA timer  | 3      | 1     | M     | Any  |
| LA  | 14     | 1     | M     | Any  |
| Optional elements present?  | 1      | O-bit |       | 0  |
| 2 LA timer  | 3      | 1     | M     | Any  |
| LA  | 14     | 1     | M     | Any  |
| Optional elements present?  | 1      | O-bit |       | 0  |
| Type 3/4 elements to follow                                       | 1      | M-bit |       | 1  |
| Type 3/4 element identifier                                       | 4      | 1     | M     | Group identity location accept                                     |
| Length indicator  | 11     | 1     | M     | 55   |
| Group identity accept/reject                                      | 1      | 1     | M     | Any  |
| Reserved  | 1      | 1     | M     | Any  |
| Optional elements present?  | 1      | O-bit |       | 1  |
| Type 3/4 elements to follow                                       | 1      | M-bit |       | 1  |
| Type 3/4 element identifier                                       | 4      | 1     | M     | Group identity downlink  |

| GSSI   | 24     |       | C     | Any   |
| Type 3/4 elements to follow?                 | 1      | M-bit |       | 0 (no more elements inside Group identity uplink element) |
| Type 3/4 elements to follow?                 | 1      | M-bit |       | 0 (no more elements in the U-LOCATION UPDATE DEMAND PDU)  |

## E.2 PDU encoding rules for MLE PDUs

### E.2.1 General PDU encoding rules for MLE PDUs

The general format of the MLE protocol PDU is defined according to table E.15.

The elements shall be transmitted in the order specified by the table with the top element being transmitted first (before interleaving). The content of an information element is represented by a binary value and the most significant bit of that binary value shall be transmitted first (before interleaving).

**Table E.15: MLE protocol PDU layout**

| Information element                     | Length   | Value            | Remark   |
|---|----------|------------------|--|
| Protocol discriminator                  | 3        | 101 <sub>2</sub> | Specifies an MLE protocol PDU  |
| PDU type                                | 3        |                  | Specifies the particular MLE protocol PDU  |
| Type 1 element (1)                      | variable |                  | See element definition for length and values   |
| Type 1 element (2)                      | variable |                  | See element definition for length and values   |
| etc.                                    | etc.     |                  | Etc.   |
| Type 1 element (m)                      | variable |                  | See element definition for length and values   |
| Conditional element to previous element | variable |                  | See element definition for length and values   |
| Type 1 element (m+1)                    | variable |                  | See element definition for length and values   |
| etc.                                    | etc.     |                  | Etc.   |
| Type 1 element (n)                      | variable |                  | See element definition for length and values   |
| Optional bit (O-bit)                    | 1        | 0                | No type 2 elements follow  |
|   |          | 1                | Type 2 elements follow   |
| Presence bit (P-bit) (1)                | 1        | 0                | The type 2 element (1) is not present  |
|   |          | 1                | The type 2 element (1) is present  |
| Type 2 element (1)                      | variable |                  | See element definition for length and values   |
| Presence bit (P-bit) (2)                | 1        | 0                | The type 2 element (2) is not present  |
|   |          | 1                | The type 2 element (2) is present  |
| Type 2 element (2)                      | variable |                  | See element definition for length and values   |
| etc.                                    | etc.     |                  | Etc.   |
| Presence bit (P-bit) (n)                | 1        | 0                | The type 2 element (n) is not present  |
|   |          | 1                | The type 2 element (n) is present  |
| Type 2 element (n)                      | variable |                  | See element definition for length and values   |
| Conditional element to previous element | variable |                  | See element definition for length and values   |
| etc.                                    | etc.     |                  | Etc.   |
| SDU                                     | variable | variable         | Encoded as nominated CMCE or MM PDU except protocol discriminator element is not present |

NOTE: The optional SDU information element is not preceded by a P-bit for the SDU.

#### Presence of O-bit and P-bit:

The O-bit is always present straight after last type 1 element unless stated otherwise in the PDU description. Also when the no type 2 elements are defined for the PDU, the O-bit shall be present and set equal to "0", unless stated otherwise in the PDU description.

In case O-bit has value "0", the PDU contains no type 2 elements; no P-bits for type 2 elements and no type 2 elements.

In case the O-bit has value 1, then at least one type 2 element follows. In this case there is P-bit for each type 2 element which is defined for the PDU; if the type 2 element is present in the PDU then the corresponding P-bit has value 1, if the type 2 element is not present, then the corresponding P-bit has value 0.

NOTE 1: There is no P-bit before an element that is conditional to another element.

NOTE 2: The PDU can contain further information after O-bit even when it is set to value "0"; the PDU can contain an SDU also in case the PDU does not contain any type 2 elements (the O-bit is set to "0").

### Length of the elements:

The length of a type 1 or type 2 element is either fixed as indicated in the "Length" column in the PDU or variable, refer to note 4. The length of an element conditional to type 1 or type 2 element is either fixed as indicated in the "Length" column in the PDU or the length may be indicated by the value of a preceding element to which this element is conditional.

NOTE 3: A conditional element may also be present in the PDU varying times as indicated by the value of a preceding element to which this element is conditional. In such case the element is marked as "Repeatable" in the PDU.

### Encoding rules for PDU:

- elements of type 1 are mandatory and shall be placed within the PDU in fixed order as specified in the PDU description tables. The type 1 elements shall be placed before any type 2 elements in the PDU encoding. In addition the PDU may contain elements that are conditional to type 1 elements; they are present only if the corresponding type 1 element has specified value. These conditional elements are placed after the type 1 elements to which they are conditional;
- elements of type 2 are optional and shall be placed within the PDU in fixed order as specified in the PDU description tables. In addition the PDU may contain elements that are conditional to type 2 elements; they are present only if the corresponding type 2 element is present and has specified value. These conditional elements are placed after the type 2 element to which they are conditional;
- elements of type SDU are placed as the last element at the end of the PDU. There is no preceding bit for the SDU element, the length of the whole PDU as indicated in the MAC header defines whether the element is present in the PDU or not.

NOTE 4: For presentation purposes a set of information elements can be defined as an information element. The set of information sub-elements may contain also optional or conditional elements and also elements consisting of set of sub-elements. The set is encoded into the PDU as if it were a single information element of the indicated type. If the information element is a set of information elements that contain either a variable number of conditional elements or optional elements then the length is marked to be variable.

The following rules shall apply for decoding of an MLE PDU:

```
DO for all Type 1 elements
  DECODE Type 1 Element
    WHILE conditional elements to the type 1 element
      DECODE conditional element
    END WHILE;
END DO;
IF explicitly defined that the PDU shall not contain an O-bit
THEN END of PDU encoding;
ELSE
  DECODE O-bit
    IF O-bit set to "Type 2 elements follow"
      DO for all possible type 2 elements
        DECODE P-bit
          IF P-bit set to "Present", decode type 2 element
            WHILE conditional element to the type 2 element
              DECODE indicated conditional element
            END WHILE;
          END IF;
        END DO;
      END IF;
    IF SDU present, decode SDU
  END ELSE.
```

The encoding rules for elements and sub-elements:

- in case the PDU information element or sub-element definition contains no "Type" column, the element/sub-element is considered to be of type 1;
- an element or sub-element may contain a set of information elements, and any individual information element in that set may be followed immediately by conditional elements to that individual information element;

NOTE 5: When no optional elements are specified for the type 1 or type 2 elements/sub-element, there is no O-bit after the last type 1 sub-element.

- a conditional information element may contain type 1 and type 2 sub-elements. In the case that at least one type 2 element is specified for the conditional element, there shall be an O-bit indicating whether the element contains any optional type 2 elements:
  - in case no optional type 2 elements are present in the element, the O-bit shall be set to value "no optional elements follow";
  - in case at least one optional type 2 element is present in the element, the O-bit shall be set to value "optional elements follow" and a P-bit shall be set for each type 2 sub-element specified for the conditional element to indicate presence of that element. The P-bit shall indicate either "type 2 element present" or "type 2 element not present".

NOTE 6: As no type 3 or type 4 sub-elements are specified for the conditional elements, there is no M-bit after the last type 2 element or P-bit indicating that the last optional type 2 element is not present.

The following rules shall apply for decoding of information element containing a set of information elements:

```

DO for all Type 1 elements
  DECODE Type 1 Element
    WHILE conditional elements to the type 1 element
      DECODE conditional element
    END WHILE;
END DO;
IF no optional information element is defined for the set of information elements
THEN END of the set of information element encoding;
ELSE
  DECODE O-bit
    IF O-bit set to "Type 2 elements follow"
      DO for all possible type 2 elements
        DECODE P-bit
          IF P-bit set to "Present", decode type 2 element
            WHILE conditional element to the type 2 element
              DECODE indicated conditional element
            END WHILE;
          END IF;
        END DO;
      END IF;
END ELSE;
END

```

The C/O/M column indicates how the presence of an information element is controlled in the PDU or element/sub-element:

- M: Mandatory information element is always present (mandatory) in the main PDU level and is always present in a sub-element, when the sub-element itself is present. The type of mandatory element is type 1;
- O: Optional information element may be present in the PDU. The protocol state or an implementation choice defines when it is present or not. The type of optional element is type 2;
- C: Conditional information element is present as defined in the PDU description. The presence depends on the value of another preceding information element. If the information element on which the conditional information element is conditional is not present then also the conditional information element is not present. The conditional information element may be also repeated as many times as indicated by a preceding information element.

## E.2.2 PDU encoding examples for MLE PDUs

Tables E.16 to E.29 present examples of proper MLE PDU encoding in specific cases.

**Table E.16: D-NWRK-BROADCAST PDU with no neighbour cell information elements**

| Information Element        | Length | Type  | C/O/M | Value            |
|----------------------------|--------|-------|-------|------------------|
| Protocol discriminator     | 3      | 1     | M     | MLE              |
| PDU Type                   | 3      | 1     | M     | D-NWRK-BROADCAST |
| Cell re-select parameters  | 16     | 1     | M     | Any              |
| Cell load CA               | 2      | 1     | M     | Any              |
| Optional elements present? | 1      | O-bit |       | 0                |

**Table E.17: D-NWRK-BROADCAST PDU with "No neighbour cell information available" indication**

| Information Element                  | Length | Type  | C/O/M | Value                                     |
|--------------------------------------|--------|-------|-------|---|
| Protocol discriminator               | 3      | 1     | M     | MLE                                       |
| PDU Type                             | 3      | 1     | M     | D-NWRK-BROADCAST                          |
| Cell re-select parameters            | 16     | 1     | M     | Any                                       |
| Cell load CA                         | 2      | 1     | M     | Any                                       |
| Optional elements present?           | 1      | O-bit |       | 1   |
| P-bit for TETRA network time element | 1      | P-bit |       | 0   |
| P-bit for Number of neighbour cells  | 1      | P-bit |       | 1   |
| Number of Neighbour cells element    | 3      | 2     | O     | "No neighbour cell information available" |

**Table E.18: D-NWRK-BROADCAST PDU with 2 neighbour cell information elements**

| Information Element                             | Length | Type  | C/O/M | Value             |
|---|--------|-------|-------|-------------------|
| Protocol discriminator                          | 3      | 1     | M     | MLE               |
| PDU Type  | 3      | 1     | M     | D-NWRK-BROADCAST  |
| Cell re-select parameters                       | 16     | 1     | M     | Any               |
| Cell load CA                                    | 2      | 1     | M     | Any               |
| Optional elements present?                      | 1      | O-bit |       | 1                 |
| P-bit for TETRA network time element            | 1      | P-bit |       | 0                 |
| P-bit for Number of neighbour cells             | 1      | P-bit |       | 1                 |
| Number of Neighbour cells element               | 3      | 2     | O     | 2                 |

| Location area (LA)                | 14     | 1     | M     | Any  |
| Optional elements present?        | 1      | O-bit |       | 0  |
| P-bit for SSI                     | 1      | P-bit |       | 0  |
| P-bit for Address extension       | 1      | P-bit |       | 0  |
| M-bit for Type 3 elements         | 1      | M-bit |       | 0  |

**Table E.28: U-RESTORE PDU with optional LA element, U-CALL RESTORE PDU does not contain type 3 elements**

| Information Element                         | Length | Type  | C/O/M | Value          |
|---|--------|-------|-------|----------------|
| Protocol discriminator                      | 3      | 1     | M     | MLE            |
| PDU Type                                    | 3      | 1     | M     | U-RESTORE      |
| Optional elements present?                  | 1      | O-bit |       | 1              |
| P-bit for MCC element                       | 1      | P-bit |       | 1              |
| P-bit for MNC element                       | 1      | P-bit |       | 1              |
| P-bit for LA element                        | 1      | P-bit |       | 1              |
| LA element                                  | 14     | 2     | O     | Any            |
| PDU Type                                    | 5      | 1     | M     | U-CALL RESTORE |
| Call identifier                             | 14     | 1     | M     | Any            |
| Request to transmit/send data               | 1      | 1     | M     | Any            |
| Other party type identifier                 | 2      | 1     | M     | SSI            |
| Other party SSI                             | 24     |       | C     | Any            |
| Optional elements present?                  | 1      | O-bit |       | 1              |
| P-bit for Basic service information element | 1      | P-bit |       | 1              |
| Basic service information element           | 8      | 2     | M     | Any            |
| M-bit (for Type 3 elements)                 | 1      | M-bit |       | 0              |

**Table E.29: U-RESTORE PDU without optional element,  
U-CALL RESTORE PDU contains type 3 element**

| Information Element                         | Length | Type  | C/O/M | Value                   |
|---|--------|-------|-------|-------------------------|
| Protocol discriminator                      | 3      | 1     | M     | MLE                     |
| PDU Type                                    | 3      | 1     | M     | U-RESTORE               |
| Optional elements present?                  | 1      | O-bit |       | 0                       |
| PDU Type                                    | 5      | 1     | M     | U-CALL RESTORE          |
| Call identifier                             | 14     | 1     | M     | Any                     |
| Request to transmit/send data               | 1      | 1     | M     | Any                     |
| Other party type identifier                 | 2      | 1     | M     | SSI                     |
| Other party SSI                             | 24     |       | C     | Any                     |
| Optional elements present?                  | 1      | O-bit |       | 1                       |
| P-bit for Basic service information element | 1      | P-bit |       | 1                       |
| Basic service information element           | 8      | 2     | M     | Any                     |
| M-bit (for Type 3 elements)                 | 1      | M-bit |       | 1                       |
| Type 3 element identifier                   | 4      | 1     | M     | Facility or Proprietary |
| Length indicator                            | 11     | 1     | M     | N                       |
| Type 3 element                              | n      | 1     | M     | Any                     |
| M-bit (for Type 3 elements)                 | 1      | M-bit |       | 0                       |

---

## Annex F (normative): TETRA frequency bands, duplex spacings and channel numbering

The usage of the TETRA frequency bands, duplex spacings and channel numbering shall be as defined in ETSI TS 100 392-15 [18].

# Annex G (normative): TETRA group management scenarios

## G.0 Introduction

TETRA group management scenarios define how group management PDUs shall be encoded in the presented scenarios.

## G.1 General requirements

The requirements are presented as a list to facilitate an easier referencing.

- 1) The structure of the D/U-ATTACH DETACH GROUP IDENTITY PDUs and U/D-ATTACH DETACH GROUP IDENTITY ACK PDUs is defined in clause 16.9 and the PDU encoding in annex E.
  - The Group identity uplink element as defined in clause 16.10.15 should have the values as defined in table G.1.

**Table G.1: Group identity uplink information values**

| Location scenario | MS location   | Group identity address type |
|-------------------|---|-----------------------------|
| 1a)               | On home system  | 00 <sub>2</sub>             |
| 1b)               | On foreign system and SwMI has not previously allocated VGSSI   | 01 <sub>2</sub>             |
| 1c)               | On foreign system and SwMI has previously allocated VGSSI (for example, if the MS wishes to detach a group) | 10 <sub>2</sub>             |

- The Group identity downlink element as defined in clause 16.10.15 should have the values as defined in table G.2.

**Table G.2: Group identity downlink information values**

| Location scenario | MS location   | Group identity address type |
|-------------------|---|-----------------------------|
| 2a                | On home system  | 00 <sub>2</sub>             |
| 2b)               | On foreign system (SwMI initiated attachment)   | 11 <sub>2</sub>             |
| 2c) i)            | On foreign system (response to 1b) above - acceptance of attachment)  | 11 <sub>2</sub>             |
| 2c) ii)           | On foreign system (response to 1b) above - rejection of attachment)   | 01 <sub>2</sub>             |
| 2d)               | On foreign system (response to 1c) above, same VGSSI)   | 10 <sub>2</sub>             |
| 2e)               | On foreign system and the foreign SwMI wishes to allocate a new VGSSI to an existing GTSI which has been allocated a VGSSI (i.e. the new VGSSI replaces the existing VGSSI) | 11 <sub>2</sub>             |
| 2f)               | On foreign system (response to group report, SwMI has previously allocated VGSSI to MS)   | 11 <sub>2</sub>             |

- 2) New group attachments/detachments cannot be mixed with the acknowledgements to requested group attachments/detachments contained in the "Group identity location accept" element of the D-LOCATION UPDATE ACCEPT PDU or the D/U-ATTACH / DETACH GROUP IDENTITY ACK PDUs. If the acknowledgement to the group attachment/ detachment request contains a group or a number of groups, those groups shall be the complete set or a subset of the group(s) in the request.
- 3) The "Group identity attach/detach mode" element of the D-ATTACH/DETACH GROUP IDENTITY ACK PDU and the "Group identity attach/detach mode" element of the "Group identity location accept" element of the D-LOCATION UPDATE ACCEPT PDU are to be marked "Reserved".

- 4) The MS shall not reject a SwMI-requested detachment; the SwMI may reject a MS-requested detachment, refer to scenario 5 (7).
- 5) Rejection of attachment is equivalent to acceptance of detachment: the group is detached. Rejection of detachment is equivalent to acceptance of attachment (subject to the restriction described in requirement 4): the group is attached.
  - In the following set of rules, "requester" refers to the sender of the D/U-ATTACH DETACH GROUP IDENTITY PDU and "responder" refers to the sender of the U/D-ATTACH DETACH GROUP IDENTITY ACK PDU.
- 6) A value of "0" (Attachment/detachment accepted) in the "Group identity accept/reject" element (D-ATTACH DETACH GROUP IDENTITY ACK PDU) or "Group identity acknowledgement type" element (U-ATTACH DETACH GROUP IDENTITY ACK PDU) indicates to the requester that all the requested attachments and/or detachments have been accepted. All or some of the accepted groups may be present in the Group identity uplink/downlink element of the acknowledgement.

Examples are:

- 6a) Request contains only attachments: all attachments are accepted and the Group identity uplink/downlink element is not present in the acknowledgement.
- 6b) Request contains only attachments: all attachments are accepted, but the Group identity uplink/downlink element in the acknowledgement contains attachment (of some/all groups) indicating a different CoU than the request.
- 6c) Request contains only attachments: all attachments are accepted, but the Group identity uplink/downlink element in the acknowledgement contains attachment (of some/all groups) indicating the attachment lifetime of the group (if different than the default attachment lifetime).
- 6d) Request contains only detachments: all detachments are accepted and the Group identity uplink/downlink element is not present in the acknowledgement.
- 6e) Several attachments and/or detachments in the request: all accepted, Group identity uplink/downlink element is not present in the acknowledgement.
- 6f) Several attachments and/or detachments in the request: all accepted but the Group identity uplink/downlink element in the acknowledgement contains attachment(s) of one or several groups that were requested to be attached, indicating different CoU than the request and/or indicating the attachment lifetime of the group (if different than the default attachment lifetime).

NOTE 1: If a detachment request is accepted, the Group identity uplink/downlink element should not be included in the acknowledgement because it gives the requester no useful information; in fact, the difference in detachment reasons between the request and response may be confusing to the requester.

- 7) A value of 1 (Attachment/detachment rejected) in the "Group identity accept/reject" element (D-ATTACH DETACH GROUP IDENTITY ACK PDU) or "Group identity acknowledgement type" element (U-ATTACH DETACH GROUP IDENTITY ACK PDU) indicates to the requester that at least one of the requested attachments and/or detachments have been rejected. All rejected groups are present in the Group identity uplink/downlink element of the acknowledgement. All or some of the accepted groups may be present in the Group identity uplink/downlink element of the acknowledgement.

Examples are (see proposal 6 for examples of acceptance of attachment/detachment):

- 7a) Request contains only attachments: one or several (maybe even all) attachments are rejected, the Group identity uplink/downlink element is included in the acknowledgement containing the rejected groups and a reject reason for each rejected group.
- 7b) Request contains only detachments: one or several (maybe even all) detachments are rejected, the Group identity uplink/downlink element is included in the acknowledgement containing the rejected groups and attachment information for each rejected group.
- 7c) Request contains attachments and detachments: at least one attachment and/or detachment is rejected, the Group identity uplink/downlink element is included in the acknowledgement containing the rejected group(s) and reject reason/attachment information for each rejected group.

- 8) If the responder accepts a group attachment or detachment request but does not include the group in the response, the responder is said to be implicitly accepting the attachment/detachment request. If the responder accepts or rejects a group attachment or detachment request and does include the group in the response, the responder is said to be explicitly accepting or rejecting the attachment/detachment request:
- 8a) To explicitly accept an attachment, the responder sets the "Group identity attach/detach type identifier" element of the "Group identity uplink" or "Group identity downlink" element to "0" (Attachment).
  - 8b) To explicitly reject an attachment, the responder sets the "Group identity attach/detach type identifier" element of the "Group identity uplink" or "Group identity downlink" element to "1" (Detachment).
  - 8c) To explicitly reject a detachment, the responder sets the "Group identity attach/detach type identifier" element of the "Group identity uplink" or "Group identity downlink" element to "0" (Attachment).
  - 8d) Detachment should not be explicitly accepted - see note 1.

NOTE 2: Implicit rejection of a group attachment or detachment request is not permitted - see requirement 7.

- 9) A MS or a SwMI may request detachment of all groups by sending a group attach/detach request without any groups. For all requests of this nature, with the exception of one solicited by a group report request, the "Group identity attach/detach mode" element shall be set to "1". ("Detach all currently active group identities and attach group identities..."); for a group report request, the "Group identity attach/detach mode" element shall be set to "0" (Amendment).
- 10) If a D/U-ATTACH DETACH GROUP IDENTITY PDU contains at least one detachment request and the "Group identity attach/detach mode" element is set to "1" (Detach all currently active group identities and attach group identities defined in the group identity downlink/uplink element), the responder shall ignore the detachment request(s).

The scenarios in clauses G.2 and G.3 define contents of the group attachment/detachment related information elements of PDUs.

In the scenarios the information contained in the PDU description tables corresponds to the following key:

- [C] denotes element upon which other elements are conditional (note that this is not a reference to annex C); and
- CoU = Class of usage.

---

## G.2 MS-INITIATED GROUP ATTACHMENT/DETACHMENT

### G.2.1 SCENARIO 1

MS requests attachment of one group; SwMI accepts attachment, ACK contains group.

#### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

#### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value), see note;
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE: The SwMI may send a different CoU value to that requested by the MS; if the MS does not accept the SwMI CoU, it may send a separate U-ATTACH/DETACH GROUP IDENTITY PDU requesting detachment of the group.

## G.2.2 SCENARIO 2

MS requests attachment of one group; SwMI accepts attachment, ACK does not contain group, see note.

#### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

#### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).

NOTE: Attachment lifetime of the group is the "default group attachment lifetime"; if the attachment lifetime of the group is different to the default, the group will be present in the ACK PDU, see scenario 1. MS assumes the CoU of the group is the CoU contained in the uplink request.

## G.2.3 SCENARIO 3

MS requests attachment of one group; SwMI rejects attachment, ACK contains group.

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.

## G.2.4 SCENARIO 4

MS requests detachment of one group; SwMI accepts detachment, ACK does not contain group.

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = 0.
- Group identity uplink:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment uplink = XX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).

## G.2.5 SCENARIO 5

MS requests detachment of one group; SwMI rejects detachment, ACK contains group.

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = 0.
- Group identity uplink:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment uplink = XX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value but probably the value held by the SwMI for this MS/Group combination);
  - Group identity address type = see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.

## G.2.6 SCENARIO 6

MS requests attachment of multiple groups; SwMI accepts all the attachments, ACK contains all the groups in the uplink request, see note 1.

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

#### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value) (see note 2);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value) (see note 2);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value) (see note 2);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE 1: The order of groups in the downlink response does not have to match the order of groups in the uplink request. For example, GROUP 2 followed by GROUP 1 followed by GROUP 3 would be a valid order in the ACK PDU above.

NOTE 2: The SwMI may send a different CoU value to that requested by the MS; if the MS does not accept the SwMI CoU, it may send a separate D-ATTACH DETACH GROUP IDENTITY requesting detachment of the group.

## G.2.7 SCENARIO 7

MS requests attachment of multiple groups; SwMI accepts all the attachments, ACK contains a subset of the groups in the uplink request (see note 1).

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.
- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value) (see note 2);
  - Group identity address type = see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.

- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value) (see note 2);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE 1: Any group contained in the uplink request but not contained in the downlink response (GROUP 2 in this example) is implicitly attached. The attachment lifetime of the group is the "default group attachment lifetime", the MS assumes the CoU of the group is the CoU contained in the uplink request.

NOTE 2: The SwMI may send a different CoU value to that requested by the MS; if the MS does not accept the SwMI CoU, it may send a separate D-ATTACH/DETACH GROUP IDENTITY requesting detachment of the group.

## G.2.8 SCENARIO 8

MS requests attachment of multiple groups; SwMI accepts all the attachments, ACK contains no groups (see note).

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

## D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 0 (Attachment/detachment accepted).
- Group identity attach/detach mode = 0 (Reserved).

NOTE: Attachment lifetime of the groups is the "default group attachment lifetime"; if the attachment lifetime of the group is different to the default, the group will be present in the ACK PDU, see scenario 6 (9). MS assumes the CoU of the group is the CoU contained in the uplink request.

## G.2.9 SCENARIO 9

MS requests attachment of multiple groups; SwMI rejects one of the attachments, ACK contains all the groups in the uplink request (see note).

## U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.
- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

## D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE: Attachment of GROUP 1 and GROUP 3 is explicitly accepted. Attachment of GROUP 2 is explicitly rejected.

## G.2.10 SCENARIO 10

MS requests attachment of multiple groups; SwMI rejects one of the attachments, ACK contains only the rejected group (see note).

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

#### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE: Attachment of GROUP 1 and GROUP 3 is implicitly accepted. Attachment of GROUP 2 is explicitly rejected.

## G.2.11 SCENARIO 11

MS requests attachment of multiple groups; SwMI rejects all the attachments, ACK contains all the groups in the uplink request (see note).

#### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = X (Either value).
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI.

#### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSSI/(V)GSSI/GTSSI-(V)GSSI = see table G.2.

NOTE: Attachment of all groups is explicitly rejected.

## G.2.12 SCENARIO 12

MS requests attachment of two groups and detachment of one group; SwMI accepts one of the attachments and rejects the detachment and the other attachment, ACK contains all the groups in the uplink request (see note).

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = 0.
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTTSI/(V)GSSI/GTTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment uplink = XX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTTSI/(V)GSSI/GTTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTTSI/(V)GSSI/GTTSI-(V)GSSI.

### D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTTSI/(V)GSSI/GTTSI-(V)GSSI = see table G.2.

- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE: Attachment of GROUP 1 is explicitly accepted. Detachment of GROUP 2 is explicitly rejected. Attachment of GROUP 3 is explicitly rejected.

## G.2.13 SCENARIO 13

MS requests attachment of two groups and detachment of one group; SwMI accepts one of the attachments and rejects the detachment and the other attachment, ACK contains a subset of the groups in the uplink request (see note).

### U-ATTACH DETACH GROUP IDENTITY

- Group identity report = 0 (Not report requested).
- Group identity attach/detach mode = 0.
- Group identity uplink {FOR GROUP 1}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment uplink = XX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.
- Group identity uplink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - CoU = XXX (Any value);
  - Group identity address type = XX (Any value) [C];
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI.

## D-ATTACH DETACH GROUP IDENTITY ACK

- Group identity accept/reject = 1 (Attachment/detachment rejected).
- Group identity attach/detach mode = 0 (Reserved).
- Group identity downlink {FOR GROUP 2}:
  - Group identity attach/detach type identifier = 0 (Attach) [C];
  - Group identity attachment lifetime = XX (Any value);
  - CoU = XXX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.
- Group identity downlink {FOR GROUP 3}:
  - Group identity attach/detach type identifier = 1 (Detach) [C];
  - Group identity detachment downlink = XX (Any value);
  - Group identity address type = see table G.2;
  - GSSI/GTSI/(V)GSSI/GTSI-(V)GSSI = see table G.2.

NOTE: Attachment of GROUP 1 is implicitly accepted. Detachment of GROUP 2 is explicitly rejected. Attachment of GROUP 3 is explicitly rejected.

---

## G.3 SwMI-INITIATED GROUP ATTACHMENT/DETACHMENT

The principles of SwMI-initiated group attachment/detachment are the same as those for MS-initiated group attachment/detachment with the following exceptions:

- 1) The PDU exchange is D-ATTACH DETACH GROUP IDENTITY / U-ATTACH DETACH GROUP IDENTITY ACK.
- 2) The "Group identity accept/reject" element in the SwMI ACK becomes a "Group identity acknowledgement type" element in the MS ACK (the bit orientation and the meaning of the bit values is identical between the two elements).
- 3) The SwMI may request that the MS does not send an ACK (via "Group identity acknowledgement request" element in the D-ATTACH DETACH GROUP IDENTITY PDU). If the MS wishes to reject a SwMI-initiated attachment or detachment but is prevented from sending an ACK by the SwMI, the MS may initiate a separate U-ATTACH DETACH GROUP IDENTITY / D-ATTACH DETACH GROUP IDENTITY ACK PDUs transaction with the SwMI.
- 4) The U-ATTACH DETACH GROUP IDENTITY ACK PDU does not contain a "Group identity attach/detach mode" element (refer to proposal 3).
- 5) SwMI requests attachment/detachment with the "Group identity downlink" element; MS requests attachment / detachment with the "Group identity uplink" element. SwMI ACKs attachment / detachment with the "Group identity downlink" element; MS ACKs attachment / detachment with the "Group identity uplink" element.
- 6) The MS may send a different CoU value in the ACK to that requested by the SwMI. If the SwMI does not accept the MS CoU, it may send a separate D-ATTACH / DETACH GROUP IDENTITY PDU enforcing detachment of the group, refer to note 1 of scenario 1.
- 7) The MS cannot reject a SwMI-requested group detachment (refer to proposal 4).

## Annex H (normative): TETRA proprietary information element owner

### H.0 General

This annex defines TETRA proprietary information element owner.

### H.1 Proprietary information element

TETRA protocols for CMCE and MM contain optional proprietary information elements. In order to identify and differentiate various implementations of the proprietary elements a proprietary element owner is defined as the first information element of the proprietary element, refer to clauses 14.8.35 and 16.10.41.

The proprietary element owner information element shall contain elements as defined in table H.1.

**Table H.1: Proprietary element owner contents**

| Information element   | Length   | Type | C/O/M | Value                 | Remark                            |
|---|----------|------|-------|-----------------------|-----------------------------------|
| Proprietary element owner   | 8        | 1    | M     | 00000000 <sub>2</sub> | Extension indicator, (see note 1) |
|   |          |      |       | 00000001 <sub>2</sub> | Owner 1                           |
|   |          |      |       | etc.                  | etc.                              |
|   |          |      |       | 11111111 <sub>2</sub> | Owner 255                         |
| Proprietary element owner extension   | Reserved | 1    | C     | All values reserved   | See note 2                        |
| NOTE 1: This value shall indicate that the proprietary element owner is indicated by the proprietary element owner extension information element. This value is not used in V2.1.1 of the present document.                 |          |      |       |                       |                                   |
| NOTE 2: This information element shall be present only when the proprietary element owner information element has the value 00000000 <sub>2</sub> . This information element is not used in V2.1.1 of the present document. |          |      |       |                       |                                   |

The proprietary element owner values are managed by a central body.

Each manufacture should have only a single value of the proprietary element owner information element. The manufacture should design his proprietary information element contents so that he can use the same proprietary element owner value for various purposes. It is recommended that the proprietary information part is coded so that it contains in the beginning a protocol identifier, a PDU type or an information element type managed by that manufacturer so that the usage of the single proprietary element owner value can be continued as long as possible.

It is allowed that multiple manufacturers use the same proprietary element owner value under responsibility of the registered owner.

### H.2 Application for the proprietary element owner value

This application form is provided under assumption that ETSI will be the central body for the management of the proprietary element owner values of V2.1.1 of the present document. The application and allocation may be implemented by other means such as a World Wide Web server application.

**PROVISION OF AND RESTRICTED USAGE UNDERTAKING**

relating to

a **proprietary element owner** information element value, to be used in mobile and line stations and in TETRA SwMIs for Terrestrial Trunked Radio (TETRA) systems.

Between

(COMPANY NAME) .....

(COMPANY ADDRESS) .....

hereinafter called: the BENEFICIARY;

and

(COMPANY NAME).....European Telecommunications Standards Institute

(COMPANY ADDRESS).....06921 Sophia Antipolis CEDEX, France

hereinafter called: the PROVIDER.

- Whereas

The BENEFICIARY has alleged that he fulfils the following criteria:

- He is a manufacturer of TETRA equipment.

The PROVIDER undertakes to give to the BENEFICIARY:

- One globally unique **proprietary element owner** information element value, registered by the PROVIDER.

The provided **proprietary element owner** information element value is filled in below by the PROVIDER when he has received and approved two signed originals of this agreement.

**Proprietary element owner:**  =    
 Decimal number  Binary number

The code above is given as a decimal (1 to 255) number, and as a 8 bit binary number (00000001<sub>2</sub> to 11111111<sub>2</sub>). The most significant digit and bit are positioned to the left.

The BENEFICIARY undertakes:

1. To apply and use the **proprietary element owner** value in accordance with rules in annex H of the present document.
2. To return the **proprietary element owner** value to the PROVIDER, within 5 years, if these has not been used.

ETSI EN 300 392-2: "Terrestrial Trunked Radio (TETRA); Voice plus Data (V+D); Part 2: Air Interface (AI)", annex H.

In case the BENEFICIARY violates any of the obligations incurred on him by the present undertaking, he shall be liable of indemnifying ETSI for all losses suffered directly or through claims from legitimate TETRA users.

All disputes which derive from the present undertaking or its interpretation shall be settled by the Court of Arbitration of the International Chamber of Commerce situated in Paris, in accordance with the procedures of this Court of Arbitration and with the application of French Law regarding questions of interpretation.

Made in two originals, one of which is for the PROVIDER, the other for the BENEFICIARY; both originals signed by a legal representative of his company/organization.

# Annex I (normative): TETRA SDS-TL Location system coding scheme information element owner

## I.0 General

This annex defines TETRA SDS-TL Location system coding scheme information element owner.

---

## I.1 Location system coding scheme information element

TETRA SDS-TL in clause 29.5.7 defines Location system coding scheme identifiers for various location information transport protocols. Some of the potential protocols are defined in the SDS-TL standard in clause 29 and some protocol will be defined independently of the clause 29. In order to identify the manufacturer specific protocols the Location system coding scheme identifiers are allocated by a central body. The manufacturer means in this context the owner of the Location system coding scheme such as a TETRA equipment manufacturer, a TETRA application designer or TETRA operator.

NOTE 1: Location system coding scheme identifiers is a generic name for location information transport protocols and is not limited to GPS only although the earlier name of the information element (GPS coding scheme) may imply that limitation.

NOTE 2: In addition to the "Location system" TETRA SDS-TL Protocol Identifier (PID) TETRA standard contains another PID for a standardized location information transport protocol, refer to ETSI TS 100 392-18-1 [19].

There is a range on the Location system coding scheme identifiers available for the manufacturer specific protocols as defined in the clause 29.5.7.

The Location system coding scheme identifier values are managed by a central body.

Each manufacture may have multiple values of the Location system coding scheme identifier information element. The manufacture may design his proprietary information element contents so that he can use the same Location system coding scheme identifier value for all purposes of location information transport protocol. The manufacturer specific Location system coding scheme information part may be coded so that it contains in the beginning a PDU type or an information element type managed by that manufacturer so that the usage of the single protocol identifier value can be used for all purposes for that protocol. The same Location system coding scheme identifier value may be used for various protocols if suitable on the manufacturers point of view.

It is allowed that multiple manufacturers, operators or application designers use the same Location system coding scheme identifier value under responsibility of the registered owner.

---

## I.2 Application for the Location system coding scheme identifier value

This application form is provided under assumption that ETSI will be the central body for the management of the SDS-TL Location system coding scheme identifier owner values of the present document. The application and allocation may be implemented by other means such as a World Wide Web server application.

**PROVISION OF AND RESTRICTED USAGE UNDERTAKING**

relating to

a SDS-TL **Location system coding scheme** information element value, to be used in mobile and line stations, in application using TETRA equipment and in TETRA SwMIs for Terrestrial Trunked Radio (TETRA) systems.

Between

(COMPANY NAME) .....

(COMPANY ADDRESS) .....

hereinafter called: the BENEFICIARY;

and

(COMPANY NAME).....European Telecommunications Standards Institute

(COMPANY ADDRESS).....06921 Sophia Antipolis CEDEX, France

hereinafter called: the PROVIDER.

- Whereas

The BENEFICIARY has alleged that he fulfils the following criteria:

- He is a manufacturer of TETRA equipment.

The PROVIDER undertakes to give to the BENEFICIARY:

- One globally unique SDS-TL **Location system coding scheme** information element value, registered by the PROVIDER.

The provided SDS-TL **Location system coding scheme** information element value is filled in below by the PROVIDER when he has received and approved two signed originals of this agreement.

SDS-TL **Location system coding scheme**:  =    
 Decimal number                      Binary number

The code above is given as a decimal (128 to 254) number, and as an 8 bit binary number (10000000<sub>2</sub> to 11111110<sub>2</sub>).  
 The most significant digit and bit are positioned to the left.

The BENEFICIARY undertakes:

- 1. To apply and use the SDS-TL **Location system coding scheme** value in accordance with rules in annex I of the present document.
- 2. To return the SDS-TL **Location system coding scheme** value to the PROVIDER, within 5 years, if these has not been used.

ETSI EN 300 392-2: "Terrestrial Trunked Radio (TETRA); Voice plus Data (V+D); Part 2: Air Interface (AI)", annex I.

In case the BENEFICIARY violates any of the obligations incurred on him by the present undertaking, he shall be liable of indemnifying ETSI for all losses suffered directly or through claims from legitimate TETRA users.

All disputes which derive from the present undertaking or its interpretation shall be settled by the Court of Arbitration of the International Chamber of Commerce situated in Paris, in accordance with the procedures of this Court of Arbitration and with the application of French Law regarding questions of interpretation.

## Annex J (normative): TETRA SDS-TL protocol identifier information element owner

### J.0 General

This annex defines TETRA SDS-TL protocol identifier information element owner.

### J.1 Protocol identifier information element

TETRA SDS-TL in clause 29.4.3.9 defines protocol identifiers for various SDS-TL protocols. Some of the potential protocols are defined in the SDS-TL standard in clause 29 and some protocol will be defined independently of the clause 29. In order to identify the manufacturer specific protocols the protocol identifiers are allocated by a central body. The manufacturer means in this context either a TETRA equipment manufacturer, or a TETRA application designer or TETRA application protocol owner.

There are two ranges on protocol identifiers available for the manufacturer specific protocols as defined in the clause 29.4.3.9 and copied in a short form into table J.1.

**Table J.1: SDS-TL protocol identifier information element contents**

| Information element   | Length | Type | C/O/M | Value  | Remark  |
|---|--------|------|-------|--|---|
| Protocol identifier   | 8      | 1    | M     | 01000000 <sub>2</sub><br>to<br>01111110 <sub>2</sub> | The SDS-TL protocol PDUs are not used (see note 1). |
|   |        |      |       | 11000000 <sub>2</sub><br>to<br>11111110 <sub>2</sub> | The SDS-TL protocol PDUs are used (see note 2).     |
|   |        |      |       | All other values                                     | These values are outside the scope of this annex.   |
| NOTE 1: For these values each SDS type 4 user data information element contains as the standardized part the protocol identifier as the first 8 bits. The rest of the user data information is outside the scope of the present document. In the application form this is indicated as "no SDS-TL service".   |        |      |       |  |   |
| NOTE 2: For these values each SDS type 4 user data information element contains as the standardized part one of the SDS-TL PDUs as defined in clause 29.4.2. The SDS-TL PDUs contain as the first information element the protocol identifier. In the application form this is indicated as "SDS-TL service". |        |      |       |  |   |

The protocol identifier values are managed by a central body.

Each manufacture may have multiple values of the protocol identifier information element. The manufacture should design his proprietary information element contents so that he can use the same protocol identifier value for all purposes of a protocol. It is recommended that the manufacturer specific protocol information part is coded so that it contains in the beginning a PDU type or an information element type managed by that manufacturer so that the usage of the single protocol identifier value can be used for all purposes for that protocol. The same protocol identifier value may be used for various protocols if suitable on the manufacturers' point of view.

It is allowed that multiple manufacturers or application designers use the same protocol identifier value under responsibility of the registered owner.

---

## J.2 Application for the protocol identifier value

This application form is provided under assumption that ETSI will be the central body for the management of the SDS-TL protocol identifier owner values of the present document. The application and allocation may be implemented by other means such as a World Wide Web server application. The applicant shall indicate the range on which the SDS-TL Protocol Identifier is applied. Only a single range can be present in each application form.

**PROVISION OF AND RESTRICTED USAGE UNDERTAKING**

relating to

a SDS-TL **protocol identifier** information element value, to be used in mobile and line stations, in application using TETRA equipment and in TETRA SwMIs for Terrestrial Trunked Radio (TETRA) systems.

Between

(COMPANY NAME) .....

(COMPANY ADDRESS) .....

.....

hereinafter called: the BENEFICIARY;

and

(COMPANY NAME).....European Telecommunications Standards Institute

(COMPANY ADDRESS).....06921 Sophia Antipolis CEDEX, France

hereinafter called: the PROVIDER.

- Whereas

The BENEFICIARY has alleged that he fulfils the following criteria:

- He is a manufacturer of TETRA equipment, or a TETRA application designer or TETRA application protocol owner.

The PROVIDER undertakes to give to the BENEFICIARY:

- One globally unique SDS-TL **protocol identifier** information element value, registered by the PROVIDER.

The BENEFICIARY applies for an SDS-TL **protocol identifier**

for no SDS-TL service:  decimal number value in range 64 to 126

for SDS-TL service:  decimal number value in range 192 to 254

The provided SDS-TL **protocol identifier** information element value is filled in below by the PROVIDER when he has received and approved two signed originals of this agreement.

SDS-TL **protocol identifier**:  =    
 Decimal number  Binary number

The code above is given as a decimal (64 to 126 or 192 to 254) number, and as a 8 bit binary number (01000000<sub>2</sub> to 01111110<sub>2</sub>.or 11000000<sub>2</sub> to 11111110<sub>2</sub>). The most significant digit and bit are positioned to the left.

The BENEFCIARY undertakes:

- 1. To apply and use the SDS-TL **protocol identifier** value in accordance with rules in annex J of the present document.
- 2. To return the SDS-TL **protocol identifier** value to the PROVIDER, within 5 years, if these has not been used.

ETSI EN 300 392-2: "Terrestrial Trunked Radio (TETRA); Voice plus Data (V+D); Part 2: Air Interface (AI)", annex J.

In case the BENEFCIARY violates any of the obligations incurred on him by the present undertaking, he shall be liable of indemnifying ETSI for all losses suffered directly or through claims from legitimate TETRA users.

All disputes which derive from the present undertaking or its interpretation shall be settled by the Court of Arbitration of the International Chamber of Commerce situated in Paris, in accordance with the procedures of this Court of Arbitration and with the application of French Law regarding questions of interpretation.

Made in two originals, one of which is for the PROVIDER, the other for the BENEFCIARY; both originals signed by a legal representative of his company/organization.

For the PROVIDER

## Annex K (informative): TETRA Mobile Country Code information element values

### K.1 Management of TETRA Mobile Country Codes

ITU-T manages TETRA Mobile Country Codes in contrary what is defined in V2.1.1 of ETSI EN 300 392-1 [6] clause 7.2.5, refer to <http://www.itu.int/>.

---

### K.2 TETRA Mobile Country Code information element values

Refer to Recommendation ITU-T E.218 [42], <http://www.itu.int/>.

---

## Annex M (informative): Table and figure numbering

Table M.1 compares table numbers of ETSI EN 300 392-2 versions up to V2.4.2 and table numbers of ETSI TS 100 392-2 and ETSI EN 300 392-2 V2.5.1, V2.5.2 and V2.6.1. In the later versions than ETSI TS 100 392-2 and ETSI EN 300 392-2 V2.5.1, V2.5.2 and V2.6.1 the table numbers may be different than those in the table M.1. Table M.1 identifies by bold font table numbers that are referenced to from other clauses than those in each editorial sub-part of ETSI EN 300 392-2 or from other TETRA specifications or standards at the time of drafting the present document. That marking may not be complete.

**Table M.1: Table numbering**

| Versions<br>V2.4.2 and V2.4.1 |           | Versions<br>V2.5.1, V2.5.2 and<br>V2.6.1 | Name  |
|-------------------------------|-----------|--|---|
| Figure                        | Clause    | Clause.figure                            |   |
| 1                             | 5.4       | 5.1                                      | Phase transitions   |
| 2                             | 6.4.1.1   | 6.1                                      | Nominal power of BS transmitters  |

Table M.2 compares figure numbers of ETSI EN 300 392-2 versions up to V2.4.2 and figure numbers of ETSI TS 100 392-2 and ETSI EN 300 392-2 V2.5.1, V2.5.2 and V2.6.1. In the later versions than ETSI TS 100 392-2 and ETSI EN 300 392-2 V2.5.1, V2.5.2 and V2.6.1 the figure numbers may be different than those in the table M.2. Table M.2 identifies by bold font figure numbers that are referenced to from other clauses than those in each editorial sub-part of ETSI EN 300 392-2 or from other TETRA specifications or standards at the time of drafting the present document. That marking may not be complete.

**Table M.2: Figure numbering**

| Versions<br>V2.4.2 and V2.4.1<br>Figure Clause |            | Versions<br>V2.5.1, V2.5.2 and<br>V2.6.1<br>Clause.figure | Name  |
|--|------------|---|---|
| 1  | 4.3        | 4.1   | Reference configuration   |
| 2  | 4.5.1      | 4.2   | V+D TDMA structure  |
| 3  | 5.4        | 5.1   | Modulation symbol constellation and possible transitions                |
| 4  | 5.7        | 5.2   | Block diagram of the modulation process                                 |

## Annex N (informative): Example for coding of SDS Transfer SDU with UDH information elements

### N.0 General

This annex lists an example for using the UDH information elements within a SDS Transfer SDU. It shows the basic procedure to decode UDH information.

### N.1 Multiple Information Elements with Network Layer User Data (Text Message)

This example shows how to send information for 3 different fictive user applications and a text message using one SDU. The following is assumed:

- 1) Three dimensional location information shall be sent including x, y, z coordinates. UDH information element ID value shall be 0xE1. The definition for the data of that protocol shall be 2 bytes for each x, y and z coordinates value.
- 2) Star time information shall be sent including standard star time format. UDH information element ID value shall be 0xE2. The definition for the data of that protocol shall be 3 bytes star time value and 4 bytes universe ID.
- 3) Speed information shall be sent including speed over ground. UDH information element ID value shall be 0xE3. The definition for the data of that protocol shall be 2 bytes for speed value.
- 4) Text message shall be sent including 11 bytes Latin-1 coded characters.

The resulting SDU would look as presented in table N.1.

**Table N.1: Example transfer SDU for multiple UDH information elements with text message**

| Information element            | Length | Value         | Remark                                 |
|--------------------------------|--------|---------------|--|
| Time stamp used                | 1      | 0x00          | No time stamp used                     |
| Text coding scheme             | 7      | 0x01          | Latin-1 coding for text message        |
| User data header length        | 8      | 0x15          | 21 byte UDH                            |
| UDH information element ID     | 8      | 0xE1          | Three dimensional location information |
| UDH information element length | 8      | 0x06          | 6 bytes (2 x, 2 y, 2 z)                |
| X-Coordinate                   | 16     | 0x0010        | 16 cm                                  |
| Y-Coordinate                   | 16     | 0x0020        | 32 cm                                  |
| Z-Coordinate                   | 16     | 0x0030        | 48 cm                                  |
| UDH information element ID     | 8      | 0xE2          | Star time information                  |
| UDH information element length | 8      | 0x07          | 7 bytes (3 time, 4 universe. ID)       |
| Star Time                      | 24     | 0xD91122      | 217.17.34 units                        |
| Universe ID                    | 32     | 0x00112233    | Andromeda                              |
| UDH information element ID     | 8      | 0xE3          | Speed information                      |
| UDH information element length | 8      | 0x02          | 2 bytes speed                          |
| Speed                          | 16     | 0x0011        | 17 km/h                                |
| Text Message                   | 88     | "The is text" | 11 bytes Latin-1 coded text            |

All these information elements or information element sets respectively are independent from each other. Since this SDU will be sent using the PI Message with User Data Header the receiving application would have to support all these information elements. That means the application will proceed the following steps:

- 1) Get transfer SDU length from lower layer (34 bytes).
- 2) Decode Time stamp used and Text coding information elements. Subtract length of both information elements (1 byte) from transfer SDU length ( $34 - 1 = 33$ ).
- 3) Get the UDH information element length value to determine the length of the UDH information element. Subtract length of UDH information element length information element (1 byte) from remaining transfer SDU length ( $33 - 1 = 32$ ). If the result is equal to the UDH information element length value (21) the SDU does not contain Network layer user data and the Text coding IE can be ignored.
- 4) Decode the first UDH information element IE ID information element and get the UDH information element IE length value (6 bytes). Process the UDH information element U IE Data (x,y,z) information element. Subtract complete length of this UDH information element set (2 + 6 bytes) from UDH information element length ( $21 - 8 = 13$ ). Use the UDH information element IE length to find the next UDH information element IE ID.
- 5) Decode the next UDH information element ID and UDH information element length (7 bytes) information elements. Process the UDH information element Data (Star time, Universe ID). Subtract complete length of this UDH information element set (2 + 7 bytes) from remaining UDH information element length ( $13 - 9 = 4$ ). Use the UDH information element length to find the next UDH information element ID.
- 6) Decode the next UDH information element ID and UDH information element length (2 bytes) information elements. Process the UDH information element IE Data (Speed) information element. Subtract complete length of this UDH information element IE set (2 + 2 bytes) from remaining UDH information element length ( $4 - 4 = 0$ ). The remainder is now 0 and that means the end of UDH information element is reached.
- 7) Subtract the remainder of UDH information element length value from the remaining transfer SDU length ( $32 - 21 = 11$ ). The result is the length of the text message. Use the Text coding IE to decode the text message.

---

# Annex O (normative): Air - Ground - Air service

## O.1 Introduction

Air - Ground - Air service describes the method of operation for Air - Ground - Air service (AGA) in TETRA systems. It serves as a specification for TETRA MSs and SwMI manufacturers to enable them to configure their MSs and systems for operation with respect to AGA functionality.

---

## O.2 Air - Ground - Air service overview

The AGA service enables TETRA MSs to operate in special situations, where access to the base station is restricted and the cell radius is controlled by round trip delay rather than by RF path loss. Examples of large cells are air cells and sea cells. These cases also exemplify the restricted use, since the capacity of these cells is usually small and ordinary MSs would not normally have access to them. This solution uses subscriber class 1 or 2 value "Highly preferred cell for subscriber class" as indication of the air cell, see clause O.4.

NOTE 1: There are also alternative ways to prefer air cells e.g. air cells with value "preferred location areas" may be stored in the MS at subscription. That method may not support migration between different networks.

Because of the low signal attenuation due to the almost line of sight propagation, the geographical size of an air cell can be much larger than that of a normal terrestrial cell. So one air cell may cover several terrestrial cells, and air cells may need to use specially designated radio channels. Refer to ETSI TR 102 021-8 [i.12].

The path delay due to the air cell size may exceed normal system capabilities and clause O.5 defines optional modifications to the air BSs and MSs to support longer path delays allowing distances at least to 80 km on phase modulation channels and on QAM channels.

NOTE 2: Based on the specifications in clause 6.4.5 the maximum allowable path delay for a normal TETRA  $\pi/4$ -DQPSK burst structure is 7 phase modulation symbols (i.e. 14  $\pi/4$ -DQPSK bits equivalent to the guard period at the end of uplink timeslot). Each symbol represents a distance of 8,33 km giving a total maximum cell radius of 58 km. Based on the specifications in clause 6.4.10 the maximum allowable path delay for a normal TETRA QAM burst structure is 1,0 QAM symbols giving a total maximum cell radius of 63 km.

Path delay on the air cells may cause the uplink slots from a far and a near MS to partly overlap, refer to clause O.5.1. So the base station shall measure the path delay and tell the MS to select a new cell before the delayed signal starts to interfere with the next slot. BS may command MS to send periodic signalling or BS may poll the MS to allow BS to detect if path delay has been exceeded.

When air MS loses air cell coverage, it is allowed to use the terrestrial cells, but it should return to an air cell as soon as possible. This is achieved by broadcasting AGA subscriber class support (either one of the "highly preferred subscriber classes", see clause O.4.7) on the air cells. If terrestrial MS are not allowed to use air cells, then they will not have a matching subscriber class profile. Additionally the SwMI may reject registrations from terrestrial MSs on air cells.

An air MS should not use a terrestrial cell, unless the aircraft is on or close to the ground.

An MS supporting AGA service with range extension may also register as a terrestrial service only MS i.e. without AGA service subscriber class, but should not try to use air cells in that case.

Clause O.3 summarizes system requirements for Air - Ground - Air services.

Clauses O.4 to O.7 define how the system requirements are implemented for AGA services.

## O.3 System requirements regarding AGA

Table O.1 describes what the various elements need to do in order to have a working AGA solution.

**Table O.1: AGA solution system requirements**

| Solution   | Air MS  | Terrestrial MS        | Air BS  | Terrestrial BS   |
|--|---|-----------------------|---|--|
| <b>Target: keep terrestrial MS away from air cell and move interfering air MS to air cell ASAP</b> |   |                       |   |  |
| Allocation of subscriber class (off-line or over the air)  | Yes   | Yes                   | Yes, if over the air is used                                      | Yes, if over the air is used   |
| Subscriber class aspects in roaming  | Prefer air cells based on highly preferred subscriber class                 | Stay out of air cells | Subscriber class broadcast with highly preferred subscriber class | Subscriber class broadcast without highly preferred subscriber class |
| Air cell preference  | Shall register as soon as an air cell becomes radio usable                  | -                     | -   | -  |
| Neighbour cells  | Continuous monitoring of neighbour cells                                    | -                     | Broadcast up to 31 neighbours                                     | Broadcast of neighbour air cells                                     |
| Registration rejection   | Remember LA rejection   | Remember LA rejection | Should reject terrestrial MS                                      | -  |
| <b>Target: air MS shall not drag beyond maximum cell size</b>                                      |   |                       |   |  |
| Path delay measurement   | Distance reporting and response to polling; only one may be used by each BS | -                     | Distance reporting or polling                                     | -  |
| Path delay   | Cell reselection if maximum path delay exceeded or almost exceeded          | -                     | Path delay measurement and notification to MS                     | -  |
| <b>Target: extend cell size to 83 km</b>   |   |                       |   |  |
| A longer guard time between bursts   | Reduce ramp-up and ramp-down times  | -                     | Look for training sequence corresponding to the longer delay      | -  |

## O.4 Signalling protocol

### O.4.1 General

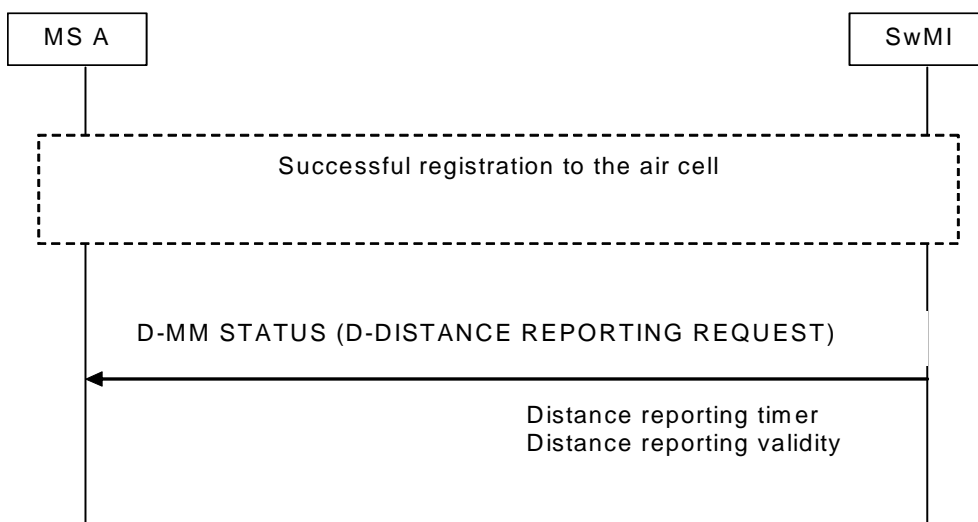

Clauses O.4.2 to O.4.7 describe mechanisms that are used to support AGA.

### O.4.2 Distance reporting

The SwMI shall implement one of the following methods of distance reporting (distance reporting or polling) to detect if the path delay of the air MS exceeds the allowable path delay.

The SwMI may order the MS to send some information during a distance reporting interval. In this case if the MS has nothing else to send the Null PDU shall be sent, see clause 16.4.11. SwMI may calculate the path delay and hence the distance of the MS from the serving base station.

The SwMI may use a variant of D-MM STATUS PDU to start the MS's distance reporting timer, refer to clause 16.10.48. The air MS shall support the D-MM STATUS PDU for distance reporting. The D-MM STATUS PDU may be sent any time, but typically it is sent immediately after the MS has registered on the air cell. While the MS is starting transmission for any reason it shall stop the reporting timer and upon ceasing the transmission MS shall start the reporting timer. Upon expiry of the reporting timer the MS shall send a Null PDU unless the MS has something else to send.

**Figure O.1: Starting distance reporting**

NOTE: Location Information Protocol may be also used to initiate periodic reporting, refer to ETSI TS 100 392-18-1 [19].

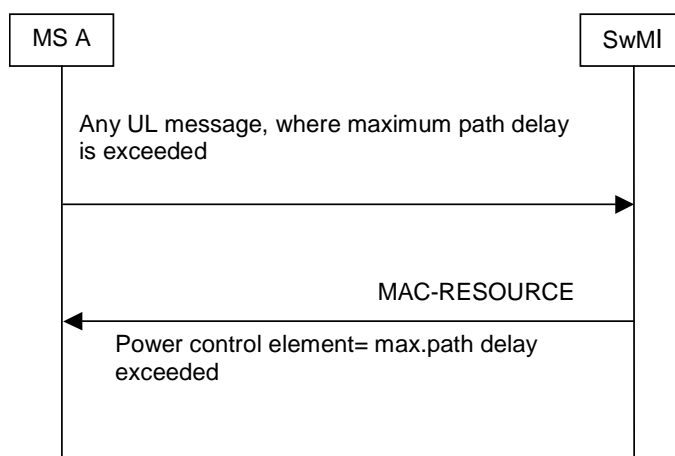

Alternatively, the SwMI may grant a slot (i.e. poll the MS) in order to make the MS transmit BL-DATA with an SDU (if ready) or a NULL PDU.

The related transmissions from the MS shall be used on traffic channels as well as control channels (MCCH/SCCH and PDCH). This applies also to the polling of MSs by the SwMI.

### O.4.3 Excessive path delay

The SwMI (base station) shall measure all transmissions from the air MS in air cells. If the path delay exceeds the limit set in the SwMI, the SwMI shall order the air MS to perform cell re-selection to another cell. This is done by including the power control element with value "maximum path delay exceeded" into any PDU addressed to the MS, see figure O.2. If the SwMI has nothing to send to the MS, it may send an empty MAC-RESOURCE PDU (without a TM-SDU).

SwMI may also indicate when the path delay is almost exceeded using the same mechanism as for the maximum path delay exceeded with the power control element value "maximum path delay almost exceeded". The actual path delay that invokes the sending information of the maximum path delay almost exceeded is outside the scope of the present document. The action of the MS on receiving this value is defined in clause 18.3.5.4.

**Figure O.2: Maximum path delay has been exceeded**

## O.4.4 Cell re-selection

An air MS shall be able to differentiate between air and terrestrial cells.

**Air cell** is identified using the generic subscriber class mechanisms- by the fact that it broadcasts support of the highly preferred subscriber class reserved for AGA operation. An air MS prefers this cell over a terrestrial cell due to the fact that it is a highly preferred subscriber class cell.

NOTE: Another solution is to store air cell identities into the air MS at subscription (preferred location area). Use of the highly preferred subscriber class mechanism for air cell preference is the recommended solution as it provides an easier global service access.

**Terrestrial cell** is identified as any cell that is not an air cell.

The air MS may be allowed to use terrestrial cells of the network, when the air cell coverage is missing (e.g. on the ground). If the MS stays registered to a terrestrial cell while it is high above ground, this could produce interference at distant terrestrial base stations on the same frequency. To avoid interference the air MS shall select the air cell as soon as it becomes radio usable, provided that the air cell supports the required services. See clause O.4.7 for preferred subscriber classes and cell re-selection.

A terrestrial MS should normally only use the air cells if it cannot find another cell that supports its subscriber class and is making an emergency call, refer to clause 14.5.7, for mobility purposes MS is allowed to use a limited set of actions refer to clause 16.4.9.

If terrestrial MSs are not allowed to use air cells then they shall not have a matching subscriber class profile. In that case SwMI shall apply subscriber class procedures, refer to clause 16.4.9 to prevent terrestrial MSs from using air cells.

The SwMI should reject registrations from terrestrial MSs on air cells with reject cause "LA not allowed (LA rejection)". The terrestrial MS shall remember that it was rejected from the (air) cell, so that it shall not try to register on the cell again, even if the cell is ranked highest in the ranking list in terms of RSSI. Refer to clause O.7.1.3.

## O.4.5 Neighbour cells

If air MSs are also to be allowed to use terrestrial cells, information for neighbouring terrestrial cells shall be included in the D-NWRK-BROADCAST, D-NWRK-BROADCAST-EXTENSION and D-NWRK-BROADCAST-DAPDU's broadcast on air cells. The maximum number of neighbouring cells shall be supported by the air MSs and the air cells. The terrestrial BSs close to expected landing sites should broadcast air cell neighbour information so that the air MSs can go to the air cell as soon as possible, refer to table O.1.

The neighbour cell information and neighbour cell information for DA information elements shall include the subscriber class element unless the neighbour and the serving cell support an identical set of subscriber classes, refer to clauses 18.5.17 and 8.5.17a, note 2 in the tables in those clauses.

When an air MS is camped on a terrestrial cell, it shall perform constant monitoring of neighbouring cells, regardless of the serving cell's RSSI, with the intention of moving to an air cell as soon as the air cell becomes usable.

## O.4.6 Base station fallback

The air MS shall favour a normal mode terrestrial base station over an air cell in fallback, if no other air cell is radio usable.

NOTE: This requirement is in contradiction with the recommendation in ETSI TR 102 021-8 [i.12], clause 4.7. The possibilities to communicate were deemed more important than possible interference prevention. In most cases an air MS user may be the only one using an air cell and base station fallback is not operationally viable. Therefore base station fallback should not be used for air cells.

## O.4.7 Subscriber class

The SwMI may assign a new subscriber class to an MS at any registration. The new subscriber class shall be effective immediately until a) the MS is assigned a new one, b) the MS is powered down or c) the MS migrates to another network, refer to clauses 16.4.9 and O.6.

Clause O.8 gives a guideline for subscriber class allocation in a network with air cells.

---

## O.5 Range extension

### O.5.1 Background for phase modulated channels

The phase modulation air interface bursts are defined in figure 9.3 in clause 9.4.4.1. The figure 9.3 copied as figure O.3 presents the TDMA frame and bursts. The related phase modulation RF output power time mask is shown in the figure 6.3 in clause 6.4.5 and is copied as figure O.4 for easier reference.

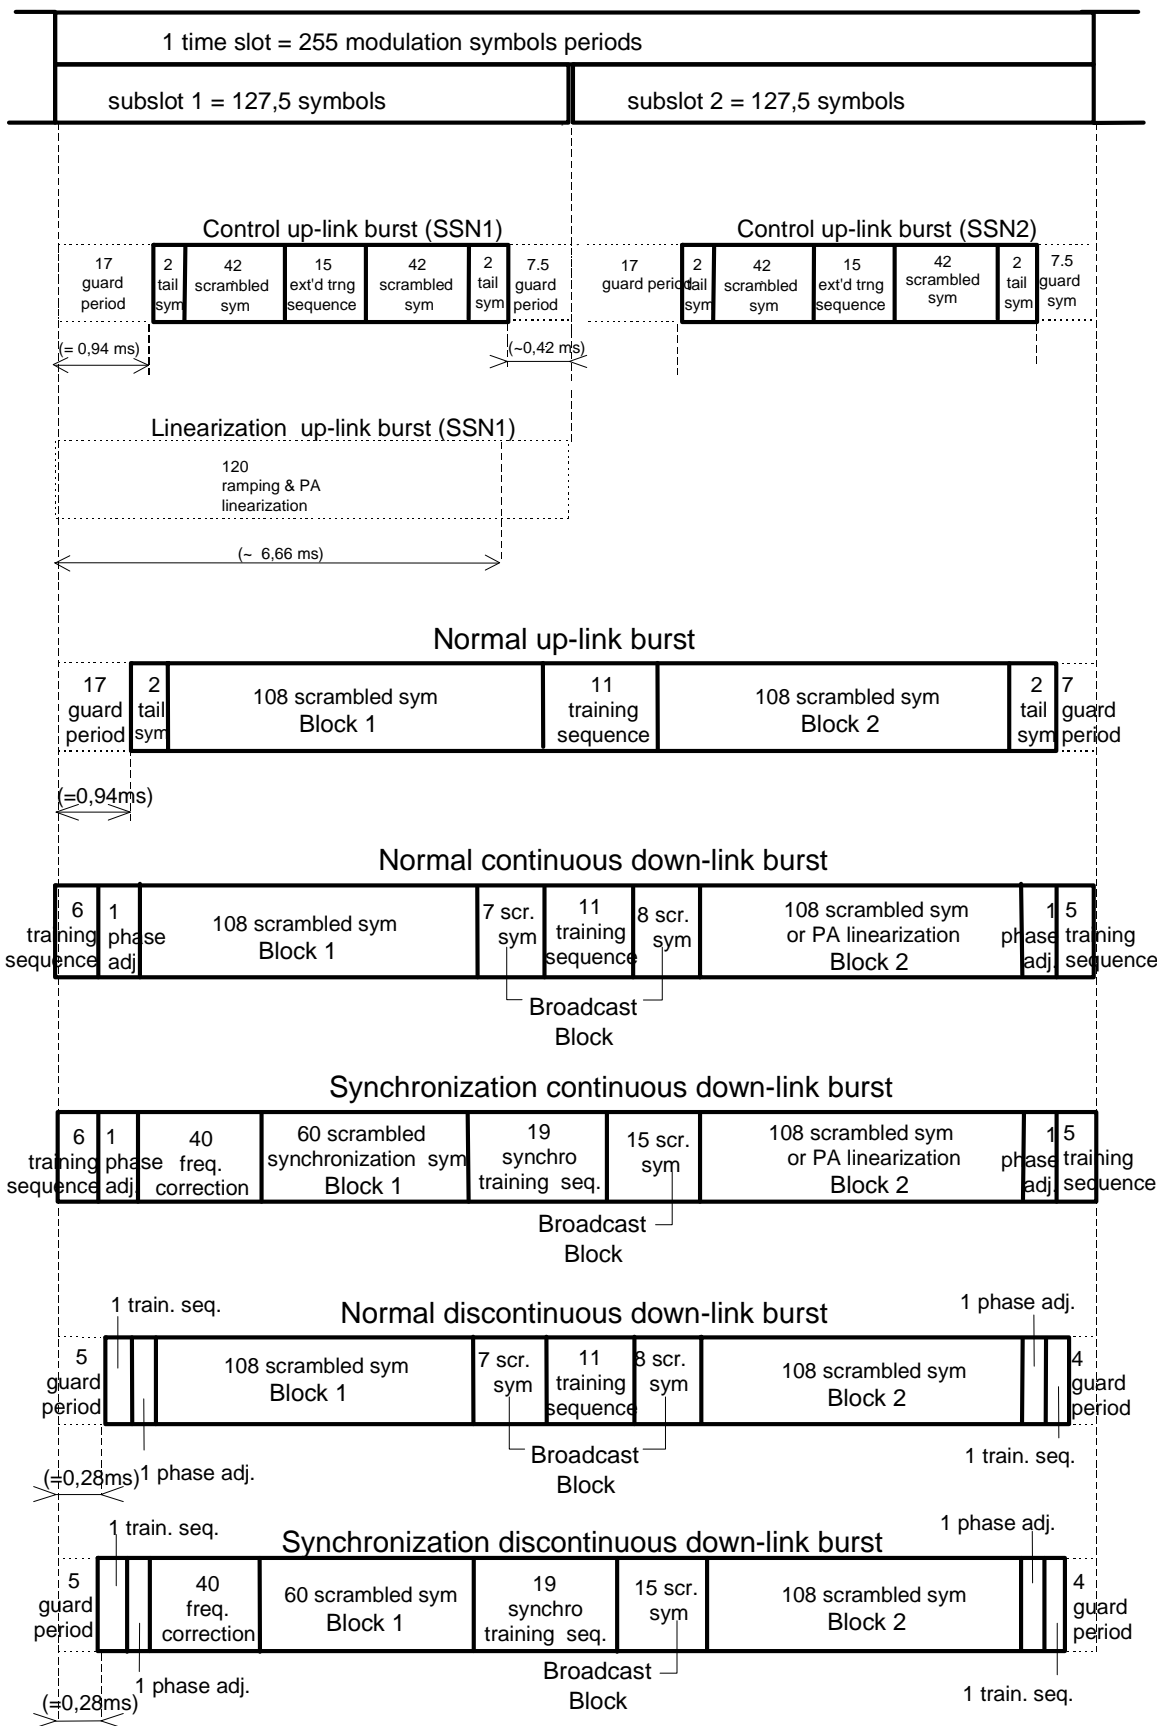

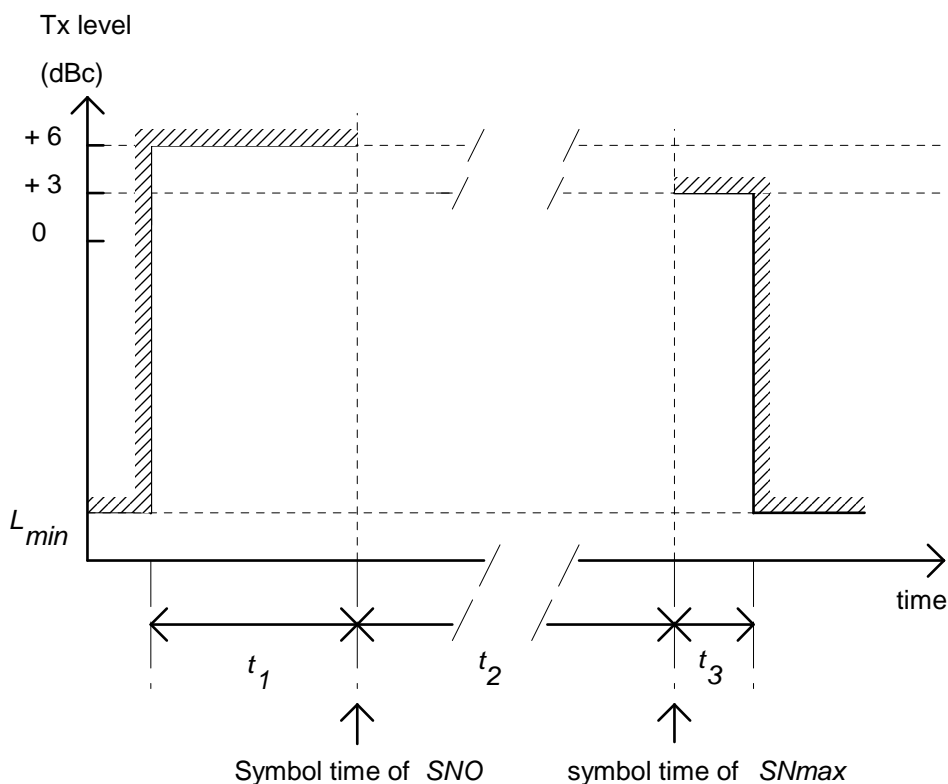

Figure O.3: TETRA uplink bursts for phase modulation

**Figure O.4: TETRA phase modulation RF output power time mask**

In the figure O.4 times  $t_1$ ,  $t_2$  and  $t_3$  are defined as in the table 6.8 of clause 6.4.5. Table O.2 presents the resulting delay tolerance when the useful part of an uplink burst (i.e. the period  $t_2$ ), transmitted on the timeslot  $TN = n$  by a far MS is not interfered by the ramp up (period  $t_1$ ) of an uplink burst from a near MS.

**Table O.2: Ramp-up and ramp-down times for terrestrial services in phase modulation symbol periods**

| Burst Type                    | $t_1$ | $t_2$ | $t_3$ | Total time | Delay tolerance |
|-------------------------------|-------|-------|-------|------------|-----------------|
| Control uplink                | 16    | 103   | 15    | 134        | 7,5             |
| Normal uplink                 | 16    | 231   | 15    | 262        | 7               |
| Linearization burst, see note | 119   | 0     | 15    | 134        | 7,5             |

NOTE: By that definition of  $t_1$  the timing of the linearization burst is referencing to the symbol time of SNmax instead of symbol time of SNO.

NOTE 1: Although the  $t_1$  and  $t_3$  values in the table O.2 are given as a number of phase modulation symbol periods the nature of ramp-up and ramp-down time does not require an alignment to a number of symbol periods.

NOTE 2: The  $t_1$  and  $t_3$  values in the table O.2 are maximum times and an implementation may use any shorter values as long as the adjacent channel requirements are fulfilled.

The delay tolerance values in the table O.2 are calculated with equation O.1:

$$\text{Delay tolerance} = \text{Timeslot length} - (\text{Information length} + \text{Max (Ramp-up time, Ramp-down time)} + \text{Filter implementation}) \quad (\text{O.1})$$

where Max (Ramp-up time, Ramp-down time) means the maximum of these two times.

**EXAMPLE:** As the length of the normal burst is 255 symbols and there are 231 phase modulation symbol periods needed for the information transmission and ramp-up time is 16 phase modulation symbol periods and one additional phase modulation symbol period is allocated for the receiver filter implementation, then the delay tolerance for the normal uplink burst is:

$$\text{Delay tolerance}_{\text{Terrestrial}} = T_d = 7 \text{ phase modulation symbol periods} \quad (\text{O.2})$$

The corresponding maximum cell radius of a TETRA terrestrial cell is:

$$R_{\text{Terrestrial\_max}} = 0,5 \times T_d \times T_s \times c = 58,3 \text{ km} \quad (\text{O.3})$$

where:

$T_d = 7$  = number of phase modulation symbol periods of delay tolerance.

$T_s$  = phase modulation symbol period =  $500/9 \mu\text{s} = 55,6 \mu\text{s}$ .

$c$  = electromagnetic wave propagation speed = 299 792 km/s.

In practice, the useful part of a phase modulation uplink burst (i.e. the period  $t_2$ ), transmitted on slot  $TN = n$  by a far MS at 58 km from the BS, is not interfered by the ramp up (period  $t_1$ ) of an uplink burst from a near MS, where the uplink burst from the near MS is transmitted on slot  $TN = (n + 1)$  (i.e. an MS at zero propagation time from the BS).

This scenario (with reference to BS receiver input) is described in the figure O.5. The time is calculated in symbol periods in the figure O.5. The figure O.5 also contains the applied solution as defined in clause O.5.2.

**Figure O.5: TETRA maximum phase modulation round-trip delay**

If the round-trip delay of the far MS exceeds 7 phase modulation symbol periods, then the near MS ramp up interferes with the last useful symbols of the far MS.

In addition to the information carrying bursts the phase modulation linearization burst as defined in clause 6.4.5 may cause interference, if it uses the whole allowed time in the time-mask.

## O.5.2 Extended range requirements for phase modulation

The range extension is implemented by shortening phase modulation ramp-up and ramp-down times in the guard period between phase modulation uplink bursts. The same adjacent channel requirements are applied as for terrestrial TETRA MSs, refer to clause 6.4, especially clauses 6.4.2.2.2 and 6.4.2.4. The air MS shall use shortened  $t_1$  and  $t_3$  values as defined in table O.3. The information part of the burst shall be in the same location as in the terrestrial service.

**Table O.3: Ramp-up and ramp-down times for AGA services in phase modulation symbol periods**

| Burst Type  | $t_1$ | $t_2$ | $t_3$ | Total time | Delay tolerance |
|---|-------|-------|-------|------------|-----------------|
| Control uplink  | 13    | 103   | 13    | 125        | 10,5            |
| Normal uplink   | 13    | 231   | 13    | 255        | 10              |
| Linearization burst, see note   | 116   | 0     | 13    | 128        | 10,5            |
| NOTE: By that definition of $t_1$ the timing of the linearization burst is referencing to the symbol time of $SN_{\max}$ instead of symbol time of $SN_0$ . |       |       |       |            |                 |

NOTE 1: Although the  $t_1$  and  $t_3$  values in the table O.3 are given as number of phase modulation symbol periods the ramp-up and ramp-down times need not be exact number of symbol periods.

EXAMPLE: Using  $t_1$  value in table O.3 for the normal uplink burst and other values as in equation O.2 the air MS delay tolerance is:

$$\text{Delay tolerance}_{\text{AGA}} = T_d = 10 \text{ phase modulation symbol periods} \quad (\text{O.4})$$

The corresponding maximum cell radius of a TETRA air cell using equation O.2 is:

$$R_{\text{AGA}_{\max}} = 0.5 \times T_d \times T_s \times c = 83,3 \text{ km} \quad (\text{O.5})$$

NOTE 2: Terrestrial MS using an air cell may reduce the maximum cell radius due to its longer ramp-up time especially, when it is close to the BS. Network operators should consider whether they allow terrestrial MSs to use air cells.

BS can control the actual maximum range using the power control information element values "maximum path delay exceeded" and "maximum path delay almost exceeded", as defined in clause 23.7.3.2.

## O.5.3 Background for QAM channels

The QAM air interface bursts are defined in figure 9.6 in clause 9.4.8.1. The figure 9.6 copied as figure O.6 presents the TDMA frame and bursts. The related QAM RF output power time mask is shown in the figure 6.4 in clause 6.4.10 and is copied as figure O.7 for easier reference.

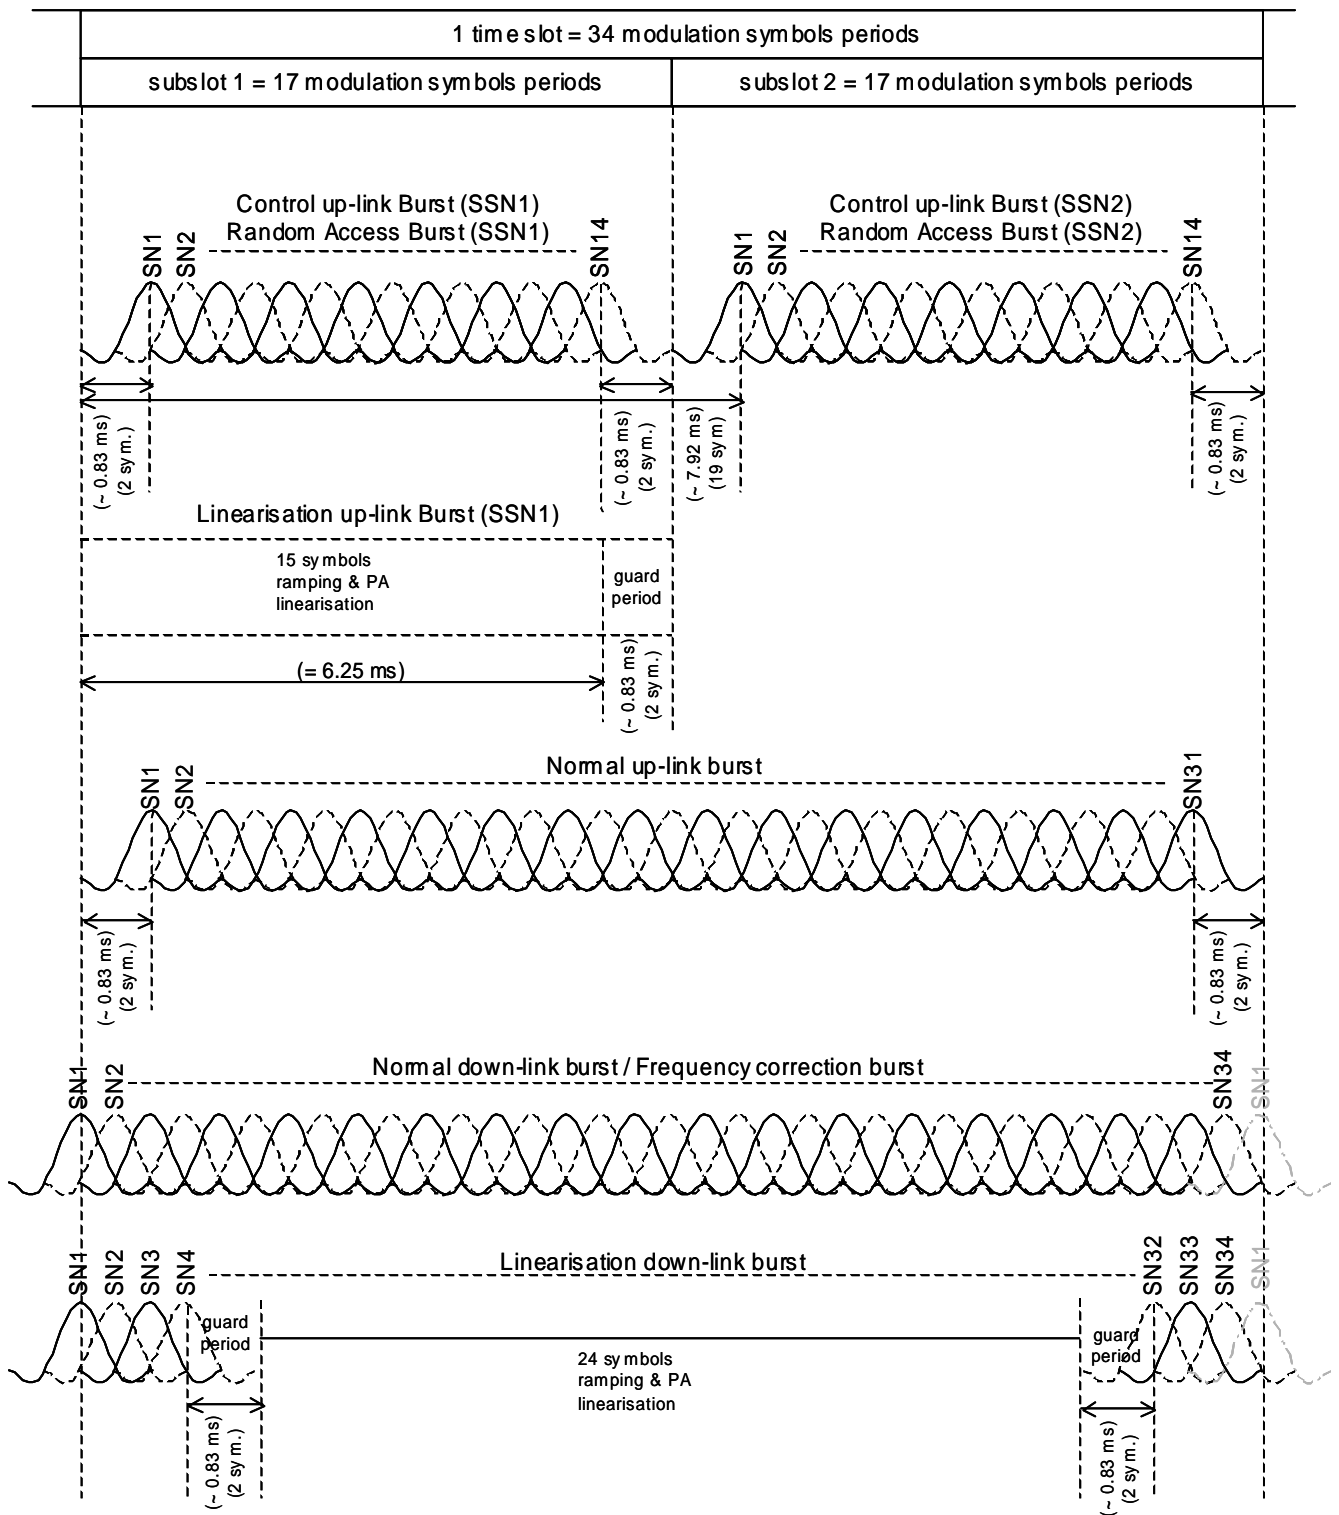

Figure O.6: TETRA uplink bursts for QAM

**Figure O.7: TETRA QAM RF output power time mask**

In the figure O.7 times  $t_1$ ,  $t_2$  and  $t_3$  are defined as in the table 6.20 of clause 6.4.10. Table O.4 presents the resulting delay tolerance when the useful part of an uplink burst (i.e. the period  $t_2$ ), transmitted on the timeslot  $TN = n$  by a far MS is not interfered by the ramp up (period  $t_1$ ) of an uplink burst from a near MS.

**Table O.4: Ramp-up and ramp-down times for terrestrial services in QAM symbol periods**

| Burst Type                      | $t_1$ | $t_2$           | $t_3$ | Total time | Delay tolerance |
|---------------------------------|-------|-----------------|-------|------------|-----------------|
| Control uplink                  | 2,0   | 13              | 2,5   | 17,5       |                 |
| Normal uplink                   | 2,0   | 30 (see note 1) | 2,5   | 34,5       | 1,0             |
| Linearization burst, see note 2 | 15,0  | 0               | 2,5   | 17,5       |                 |

NOTE 1: In the case of single slot transmission.  
 NOTE 2: By that definition of  $t_1$  the timing of the linearization burst is referencing to the symbol time of SN- $Q_{max}$  instead of symbol time of SN- $Q_1$ .  
 NOTE 3: Symbol synchronization time is included in  $t_1$  and  $t_3$ .

NOTE 1: Although the  $t_1$  and  $t_3$  values in the table O.4 are given as a number of QAM symbol periods the nature of ramp-up and ramp-down time does not require an alignment to a number of symbol periods.

NOTE 2: The  $t_1$  and  $t_3$  values in the table O.4 are maximum times and an implementation may use any shorter values as long as the adjacent channel requirements are fulfilled.

The delay tolerance values in the table O.4 are calculated with equation O.6:

$$\text{Delay tolerance} = \text{Timeslot length} - (\text{Information length} + \text{Max (Ramp-up time, Ramp-down time)} + \text{Symbol synchronization time} + \text{Filter implementation}) \quad (\text{O.6})$$

where Max (Ramp-up time, Ramp-down time) means the maximum of these two times.

**EXAMPLE:** As the timeslot length is 34 QAM symbol periods and there are 30 QAM symbol periods needed for the information transmission and ramp-down time is 2,5 QAM symbol periods and an additional 0,5 QAM symbol time is allocated for the symbol synchronization and no QAM symbol periods are allocated for receiver filter implementation (included in the ramp-down time), then the delay tolerance for the normal uplink burst is:

$$\text{Delay tolerance}_{\text{Terrestrial}} = T_d = 1,0 \text{ QAM symbol periods} \quad (\text{O.7})$$

The corresponding maximum cell radius of a TETRA terrestrial cell is:

$$R_{\text{Terrestrial\_max}} = 0,5 \times T_d \times T_s \times c = 62,5 \text{ km} \quad (\text{O.8})$$

where:

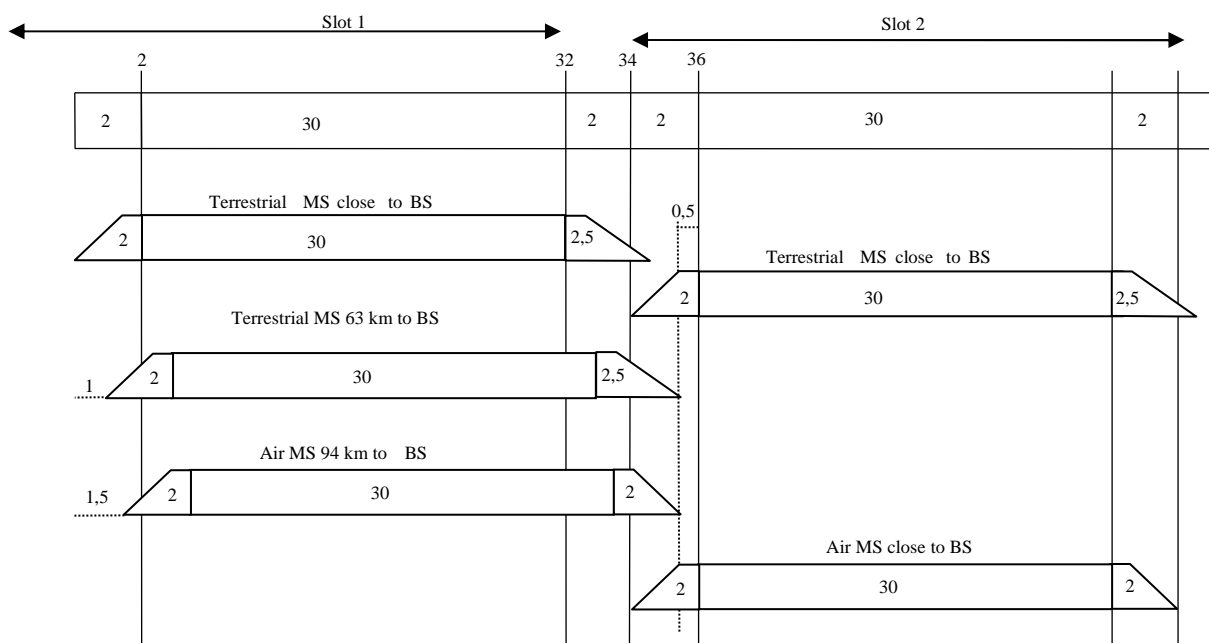

$T_d = 1,0$  = number of QAM symbol periods of delay tolerance.

$T_s$  = QAM symbol period =  $1/2 \text{ 400 s} = 417 \text{ }\mu\text{s}$ .

$c$  = electromagnetic wave propagation speed =  $299 \text{ 792 km/s}$ .

In practice, the useful part of a QAM uplink burst (i.e. the period  $t_2$ ), transmitted on slot  $TN = n$  by a far MS at 62,5 km from the BS, is not interfered by the ramp up (period  $t_1$ ) of an uplink burst from a near MS, where the uplink burst from the near MS is transmitted on slot  $TN = (n + 1)$  (i.e. an MS at zero propagation time to the BS).

This scenario (with reference to BS receiver input) is described in the figure O.8. The time is calculated in QAM symbol periods in the figure O.8. Figure O.8 also contains the applied solution as defined in clause O.5.3.

**NOTE:** Symbol synchronization time is included in ramp-up and ramp-down times.

**Figure O.8: TETRA maximum QAM round-trip delay**

If the round-trip delay of the far MS exceeds one QAM symbol period, then the near MS ramp up interferes with the last useful symbols of the far MS.

In addition to the information carrying bursts the QAM linearization burst as defined in clause 6.4.5 may cause interference, if it uses the whole allowed time in the time-mask.

## O.5.4 Extended range requirements for QAM

The range extension is implemented by shortening QAM ramp-down times in the guard period between QAM uplink bursts. The same adjacent channel requirements are applied as for terrestrial TETRA MSs, refer to clause 6.4, especially clauses 6.4.9.2.2 and 6.4.9.4. The air MS shall use shortened  $t_3$  values as defined in table O.5. The information part of the burst shall be in the same location as in the terrestrial service.

**Table O.5: Ramp-up and ramp-down times for AGA services in QAM symbol periods**

| Burst Type                      | $t_1$ | $t_2$           | $t_3$ | Total time | Delay tolerance |
|---------------------------------|-------|-----------------|-------|------------|-----------------|
| Control uplink                  | 2,0   | 13              | 2,0   | 17,0       |                 |
| Normal uplink                   | 2,0   | 30 (see note 1) | 2,0   | 34,0       | 1,5             |
| Linearization burst, see note 2 | 15,0  | 0               | 2,0   | 17,0       |                 |

NOTE 1: In the case of single slot transmission.  
 NOTE 2: By that definition of  $t_1$  the timing of the linearization burst is referencing to the symbol time of SN-Q<sub>max</sub> instead of symbol time of SN-Q<sub>0</sub>.  
 NOTE 3: Symbol synchronization time is included in  $t_1$  and  $t_3$ .

NOTE 1: Although the  $t_1$  and  $t_3$  values in the table O.5 are given as number of QAM symbol periods the ramp-up and ramp-down times need not be exact number of symbol periods.

EXAMPLE: Using  $t_3$  value in table O.5 for the normal uplink burst and other values as in equation O.6 the air MS delay tolerance is:

$$\text{Delay tolerance}_{\text{AGA}} = T_d = 1,5 \text{ QAM symbol periods} \quad (\text{O.9})$$

The corresponding maximum cell radius of a TETRA air cell using equation O.8 is:

$$R_{\text{AGA\_max}} = 0.5 \times T_d \times T_s \times c = 93,7 \text{ km} \quad (\text{O.10})$$

NOTE 2: Terrestrial MS using an air cell may reduce the maximum cell radius due to its longer ramp time(s). Network operators should consider whether they allow terrestrial MSs to use air cells.

BS can control the actual maximum range using the power control information element values "maximum path delay exceeded" and "maximum path delay almost exceeded", as defined in clause 23.7.3.2.

---

## O.6 Subscriber class procedures

### O.6.1 Purpose of the subscriber class

AGA service requires that SwMI applies subscriber class procedures to prevent terrestrial MSs to use air cells, refer to clauses 14.5.7, O.4.7 and O.7.1.2.

The SwMI may include the subscriber class element in all cases of location update signalling. If the SwMI sends the optional subscriber class element then the MS shall use the new subscriber class profile as defined in clause 16.4.9.

### O.6.2 Preferred subscriber classes

The values for the subscriber class information elements in amended clauses 16.10.49 and 18.5.22 to support AGA service and to allow a more flexible control of cell re-selection in some other cases are defined in clauses O.7.1.2 and O.7.1.3.

The subscriber class element shall be broadcasted by the SwMI to indicate which subscriber classes are supported on the cell as defined in the table O.7. The first two subscriber classes are the highly preferred subscriber classes. Refer to clause O.8 how those are used for the AGA service.

## O.7 Amendments and modifications due to the AGA service

### O.7.1 Modified information elements

#### O.7.1.1 General

In order to support protocol defined in clauses O.4 to O.6 some of the air interface protocol PDU information elements shall be modified as presented in clauses O.7.1.2 to O.7.1.4.

#### O.7.1.2 Amendment to clause 16.10.49 Subscriber class

The subscriber class information element shall subdivide the MS population in up to 16 classes (see definition) represented as a bit map as defined in table O.6.

**Table O.6: Subscriber class information element**

| Information element | Length | Value | Remark   |
|---------------------|--------|-------|--|
| Class 1             | 1      | 0     | Not a member of highly preferred cell subscriber class 1 |
|                     |        | 1     | Member of highly preferred cell subscriber class 1       |
| Class 2             | 1      | 0     | Not a member of highly preferred cell subscriber class 2 |
|                     |        | 1     | Member of highly preferred cell subscriber class 2       |
| Class 3             | 1      | 0     | Not a member of subscriber class 3                       |
|                     |        | 1     | Member of subscriber class 3                             |
| Class 4             | 1      | 0     | Not a member of subscriber class 4                       |
|                     |        | 1     | Member of subscriber class 4                             |
| Class 5             | 1      | 0     | Not a member of subscriber class 5                       |
|                     |        | 1     | Member of subscriber class 5                             |
| etc.                | 1      | 0     | Not a member of subscriber class n                       |
|                     |        | 1     | Member of subscriber class n                             |
| Class 16            | 1      | 0     | Not a member of subscriber class 16                      |
|                     |        | 1     | Member of subscriber class 16                            |

#### O.7.1.3 Amendment to clause 18.5.22 Subscriber class

The subscriber class information element shall be used by the SwMI to indicate which subscriber classes are allowed to use this cell as defined in table O.7.

**Table O.7: Subscriber class information element**

| Information element | Length | Value | Remark                                     |
|---------------------|--------|-------|--|
| Class 1             | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Highly preferred cell for subscriber class |
| Class 2             | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Highly preferred cell for subscriber class |
| Class 3             | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Subscriber class supported on cell         |
| Class 4             | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Subscriber class supported on cell         |
| Class 5             | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Subscriber class supported on cell         |
| etc.                | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Subscriber class supported on cell         |
| Class 16            | 1      | 0     | Subscriber class not supported on cell     |
|                     |        | 1     | Subscriber class supported on cell         |

## O.7.1.4 Modification of clause 21.5.3 Power control

For the BSs supporting AGA service the power control information element shall be modified as presented in the table O.8.

**Table O.8: Power control information element contents**

| Information element | Length  | Type | Value             | Remark  |
|---------------------|---|------|-------------------|---|
| Power control       | 4   | M    | 0000 <sub>2</sub> | No change in power  |
|                     |   |      | 0001 <sub>2</sub> | Increase power by 1 step  |
|                     |   |      | 0010 <sub>2</sub> | Increase power by 2 steps   |
|                     |   |      | 0011 <sub>2</sub> | Increase power by 3 steps   |
|                     |   |      | 0100 <sub>2</sub> | Increase power by 4 steps   |
|                     |   |      | 0101 <sub>2</sub> | Increase power by 5 steps   |
|                     |   |      | 0110 <sub>2</sub> | Increase power by 6 steps or maximum path delay almost exceeded, see note |
|                     |   |      | 0111 <sub>2</sub> | Maximum path delay exceeded   |
|                     |   |      | 1000 <sub>2</sub> | Revert to open loop power control   |
|                     |   |      | 1001 <sub>2</sub> | Decrease power by 1 step  |
|                     |   |      | 1010 <sub>2</sub> | Decrease power by 2 steps   |
|                     |   |      | 1011 <sub>2</sub> | Decrease power by 3 steps   |
|                     |   |      | 1100 <sub>2</sub> | Decrease power by 4 steps   |
|                     |   |      | 1101 <sub>2</sub> | Decrease power by 5 steps   |
| 1110 <sub>2</sub>   | Decrease power by 6 steps   |      |                   |   |
| 1111 <sub>2</sub>   | Radio uplink failure  |      |                   |   |
| NOTE:               | The interpretation of the value 0110 <sub>2</sub> depends on whether or not it is received by an air MS using an air cell. If the value 0110 <sub>2</sub> is received by an MS that has indicated it supports the air to ground service (see clause 16.10.10a) and is currently using an air cell as defined in clause O.4.4, the value 0110 <sub>2</sub> shall be interpreted as indicating "maximum path delay almost exceeded". In all other cases, the value 0110 <sub>2</sub> shall be interpreted as "increase power by 6 steps". |      |                   |   |

## O.7.2 Modified protocols

### O.7.2.1 General

In order to support AGA service protocol defined in clauses O.4 to O.6 the air interface protocol shall be modified as defined in clauses O.7.2.2 to O.7.2.4.

### O.7.2.2 Monitoring modification of clauses 18.3.4.2 and 18.3.4.5.1

While attached to a terrestrial cell the air MS shall monitor neighbour cells continuously and the MLE shall not issue a TL-MONITOR-LIST request parameter with an empty list of neighbour cell channels as parameter. Refer to clause O.4.4.

While attached to an air cell the air MS may monitor neighbour cells continuously in order to better support all requirements in clause O.7.2.3.

### O.7.2.3 MS cell selection modification of clause 18.3.4.5.7

In order to force air MS to use air cells also at low altitudes the air MS cell selection protocol as defined in clause 18.3.4.5.7 shall be modified as presented in the following paragraphs of the present clause.

If the air MS supports highly preferred bits, the highest-ranked highly preferred cell (i.e. where the cell broadcast and the subscriber class profile have a match in this bit position) shall be selected as soon as it becomes:

- radio usable;

- offers adequate service; and
- the current serving cell is not a highly preferred cell.

Preferred cells are used for subscriber based cell precedence (priority cell in "BS service details" element of SYSINFO broadcast and priority cell in "BS service details DA" element of SYSINFO-DA broadcast affect all MSs). Preferred cell affects only those MSs that have a matching subscriber class profile, the MS shall combine the match with other services to order the cells in the ranking list.

The criteria in clause 18.3.4.5.7 "Criteria for initiating the cell re-selection procedures" shall be appended with the following conditions that shall cause the air MS to rate a neighbour cell to have better service than the current serving cell:

- The neighbour cell is a highly preferred cell for the MS's subscriber class but the serving cell is not. This condition shall also override the postponement of cell re-selection due to ongoing circuit mode call.

In addition to those ranking reasons air MS may use the criteria defined in clause 18.3.4.5.7:

- the MS subscriber class is supported on the neighbour cell but not on the serving cell;
- the neighbour cell supports system-wide services and the serving cell does not;
- the neighbour cell is a priority cell and the serving cell is not a priority cell;
- the neighbour cell supports a service (i.e. TETRA voice, circuit mode data or TETRA packet data (SNDP) services) which is not supported by the serving cell and the air MS prefers that service to be available;
- the neighbour cell supports a modulation mode (e.g.  $\pi/4$ -DQPSK, D8PSK, QAM) which is not supported by the serving cell and the MS prefers that modulation mode to be available;
- the neighbour cell supports a higher bandwidth matching the MS's capabilities than does the serving cell, and the MS prefers the ability to use that higher bandwidth;
- the neighbour cell supports QoS negotiation during PDP context activation and the serving cell does not, and the MS prefers the use of services accessed via QoS negotiation (e.g. scheduled access or any QoS other than background class with unspecified throughput, reliability and delay);
- the neighbour cell supports air interface encryption, the serving cell does not and the air MS prefers that air interface encryption is available;
- the cell load indicates that the neighbour cell is more lightly loaded than the serving cell;
- the neighbour cell is a preferred cell (or "home cell") or belongs to a preferred LA;
- the neighbour cell is a CA cell, the present cell is a DA cell and the MS prefers to use a CA cell;
- the neighbour cell is a DA cell, the present cell is a CA cell and the MS prefers to use a DA cell;
- the neighbour cell is a wide-area cell, the present cell is not a wide-area cell, and the MS prefers to use a wide-area cell (see note); and
- the neighbour cell is not a wide-area cell, the present cell is a wide-area cell, and the MS prefers not to use a wide-area cell (see note).

NOTE: An MS may be configured to prefer using wide-area cells or to prefer not using wide-area cells. Or it may have no particular preference. Or its preference may depend on its present activities.

The MS supporting AGA service should choose to initiate cell re-selection as soon as the neighbour cell becomes radio usable as defined in clause 18.3.4.5.6. If there is more than one neighbour cell which is radio usable, the air MS should choose the one which has the highest ranking in the ranking list and which best satisfies the service requirements for the air MS.

### O.7.2.4 Modification of clause 23.4.4.3

The air MS closed loop power control shall be modified on the Power control information element so that an MS that has indicated it supports the air to ground service (see clause 16.10.10a) and is currently using an air cell as defined in clause O.4.4 shall interpret the information element value "0110<sub>2</sub>" as "Maximum path delay almost exceeded" and upon reception of that value should start cell re-selection and not to increase output power, refer to clause O.4.3.

---

## O.8 Example of subscriber class values used by operators and users in some networks

In order to promote interoperability, some values of subscriber class are defined and used by operators, users and manufacturers and presented in the table O.9. This definition facilitates inter-operability and supports very wide-area roaming and migration of air MSs, subject to operator and user subscription agreement.

**Table O.9: Subscriber class information element values for AGA service**

| Information element | Length | Value | Remark                                     |
|---------------------|--------|-------|--|
| Class 1             | 1      | any   | Not defined by the present annex           |
| Class 2             | 1      | 1     | Highly preferred cell for subscriber class |
| Class 3             | 1      | any   | Not defined by the present annex           |
| Class 4             | 1      | any   | Not defined by the present annex           |
| Class 5             | 1      | any   | Not defined by the present annex           |
| Class 6             | 1      | any   | Not defined by the present annex           |
| Class 7             | 1      | any   | Not defined by the present annex           |
| Class 8             | 1      | any   | Not defined by the present annex           |
| Class 9             | 1      | any   | Not defined by the present annex           |
| Class 10            | 1      | any   | Not defined by the present annex           |
| Class 11            | 1      | any   | Not defined by the present annex           |
| Class 12            | 1      | any   | Not defined by the present annex           |
| Class 12            | 1      | any   | Not defined by the present annex           |
| Class 14            | 1      | any   | Not defined by the present annex           |
| Class 15            | 1      | any   | Not defined by the present annex           |
| Class 16            | 1      | any   | Not defined by the present annex           |

---

## O.9 Requirements for air MSs

On transmitter characteristics air phase modulated MSs shall conform to requirements in clause 6.4 with additional requirements as defined in clause O.5.2 and air QAM MSs shall conform to requirements in clause 6.4 with additional requirements as defined in clause O.5.3.

On signalling protocol air MSs shall behave as defined in clauses O.4, O.6 and O.7.2.

Air MSs shall utilize amended information elements as defined in clause O.7.1.

---

## O.10 Requirements for AGA BSs

Based on specifications in clause O.5.2 the maximum allowable path delay for phase modulation is 10,5 phase modulation symbol periods. The air BS receiver shall apply at least that large synchronization search window in order to receive bursts from near-by and distant air MSs, when range extension is supported for phase modulation.

Based on specifications in clause O.5.3 the maximum allowable path delay for QAM is 1,5 QAM symbol periods. The air BS receiver shall apply at least that large synchronization search window in order to receive bursts from near-by and distant air MSs, when range extension is supported for QAM.

NOTE: The air MSs may use a shorter ramp-up period on phase modulation and a shorter ramp-down period on QAM than the ones normally used for terrestrial services and that may affect to the design of the AGC mechanism of BSs.

AGA BSs should use signalling protocol as defined in clauses O.4, O.6 and O.7.2.

AGA BS shall use the signalling protocol information elements as defined in clause O.7.1.

In order to reduce interference from air MSs the BS may use closed loop power control (where applicable) and/or use a suitable low value for the MS\_TXPWR\_MAX\_CELL in the SYSINFO, SYSINFO-Q and SYSINFO-DA PDU broadcasts, refer to clause 23.4.4.2.

## Annex P (normative): QAM modulation symbol allocations and symbol set definitions

### P.1 QAM modulation symbol sub-carrier allocation

#### P.1.0 General

Clause 9.4.8.2 describes the sub-carrier symbol sets. Clauses P.1.1 to P.1.7 define how symbol sets are allocated within bursts.

#### P.1.1 Control uplink Burst (CB)

The allocation of the sub-carrier symbols in the CB shall be in accordance with tables P.1 to P.4.

**Table P.1: Allocation of sub-carrier symbols in CB for 8 sub-carriers (25 kHz) case**

|   | 1  | 2   | 3  | 4   | 5   | 6   | 7   | 8   | 9   | 10  | 11  | 12  | 13  | 14  | ←i |
|---|----|-----|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|----|
| 0 | S1 | S9  | D1 | D7  | D15 | P1  | D25 | D33 | D41 | P5  | D51 | D59 | D67 | P9  |    |
| 1 | S2 | S10 | H1 | D8  | D16 | H3  | D26 | D34 | D42 | H5  | D52 | D60 | D68 | H7  |    |
| 2 | S3 | S11 | D2 | D9  | D17 | P2  | D27 | D35 | D43 | P6  | D53 | D61 | D69 | P10 |    |
| 3 | S4 | S12 | D3 | D10 | D18 | D23 | D28 | D36 | D44 | D49 | D54 | D62 | D70 | D75 |    |

tj

The allocation of the sub-carrier symbols and their content are presented in table P.7.

**Table P.7: Random Access Uplink Burst (CB)**

| SS Set<br>(see note) | Number of<br>SS symbols | Set content                 | BNmax          | Definition           |
|----------------------|-------------------------|-----------------------------|----------------|----------------------|
| S1 to S16            | 16                      | Uplink sync sequence set    | not applicable | See clause 9.4.8.3.2 |
| P1 to P12            | 12                      | Half-slot uplink pilots set | not applicable | See clause 9.4.8.3.4 |
| D1 to D84            | 84                      | Random access data set      | 168            | See clause 8         |

NOTE: SS is an abbreviation of sub-carrier symbol.

## P.1.3 Linearization uplink Burst (LB)

The LB may be used by the MSs to linearize their transmitters. The LB contains no useful symbols and its timing shall only be determined by the time mask (see clause 6.4.10).

## P.1.4 Normal Uplink Burst (NUB)

The allocation of the sub-carrier symbols in the NUB shall be in accordance with tables P.8 to P.11. The NUB shall be used by MS to transmit control messages to the BS.

Table P.8: Allocation of sub-carrier symbols in NUB for 8 sub-carriers (25 kHz) case

| NOTE: SS is an abbreviation of sub-carrier symbol. |                   |                      |                             |                |       |       |                      |

## P.1.5 Normal Downlink Burst (NDB)

The allocation of the sub-carrier symbols in the NDB shall be in accordance with tables P.13 to P.16. The NDB shall be used by the BS to transmit control messages to the MS.

Table P.13: Allocation of sub-carrier symbols in NDB for 8 sub-carriers (25 kHz) case

NOTE: SS is an abbreviation of sub-carrier symbol.

## P.1.6 Linearization downlink burst (LDB)

The linearization downlink burst may be used by the BS to linearize its transmitter. Part of the linearization downlink burst contains non useful symbols and its timing during the linearization portion shall be determined only by the time mask (see clause 6.4.10).

The allocation of the sub-carrier symbols in the LDB shall be in accordance with tables P.18 to P.21.

**Table P.18: Allocation of sub-carrier symbols in LDB for 8 sub-carriers (25 kHz) case**

| 150 kHz  | S1 to S72            | 72                      | Downlink sync sequence set        | See clause 9.4.8.3.3 |
|  | Z1 to Z120           | 120                     | Linearization downlink zeroed set | See clause 9.4.8.3.8 |
|  | FiA1 to FiA144       | 144                     | Filler set A                      | See clause 9.4.8.3.7 |
| NOTE: SS is an abbreviation of sub-carrier symbol. |                      |                         |                                   |                      |

## P.1.7 Frequency Correction downlink burst (FCB)

The allocation of the modulation symbols in the frequency correction downlink burst shall be in accordance with tables P.23 to P.26. The frequency correction downlink burst shall be used by BSs to aid the MSs adjust their frequency and to broadcast synchronization messages to the MSs.

**Table P.23: Allocation of sub-carrier symbols in FCB for 8 sub-carriers (25 kHz) case**

|   |    |     |    |     |     |     |     |     |     |     |    |     |     |      |      |     |      |      |      |      |     |      |      |      |      |     |      |       |       |       |     |       |       |       |    |

ij

The allocation of the sub-carrier symbols and their content are presented in Table P.27. For this type of burst, the data set uses only 4-QAM modulation sub-carrier symbols.

**Table P.27: Frequency Correction Burst (FCB) for QAM**

| Channel Bandwidth | SS Set        | Number of SS symbols | Set content                     | Bnmax          | Definition            |

## P.2 Burst sub-carrier symbol sets

### P.2.1 Uplink sync sequence set

The numbering and use of this symbol set is defined in clause 9.4.8.3.2. The amplitude of the symbols is as described in clause 5.13. The symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. The values of the phases shall be as expressed in tables P.28 to P.31.

**Table P.28: Uplink sync sequence set USS8 phase values as a multiple of  $\pi$  radians**

## P.2.3 Half-slot uplink pilots set

The numbering and use of this symbol set is defined in clause 9.4.8.3.4. The amplitude of the symbols is as described in clause 5.13. The symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. The values of the phases shall be as expressed in tables P.36 to P.39.

**Table P.36: Half-slot Uplink Pilots Set HUPS8 phase values as a multiple of  $\pi$  radians**

## P.2.4 Full-slot uplink pilots set

The numbering and use of this symbol set is defined in clause 9.4.8.3.5. The amplitude of the symbols is as described in clause 5.13. The symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. The values of the phases shall be as expressed in tables P.40 to P.43.

**Table P.40: Full-slot Uplink Pilots Set FUPS8 phase values

## P.2.5 Full-slot downlink pilots set

The numbering and use of this symbol set is defined in clause 9.4.8.3.5. The amplitude of the symbols is as described in clause 5.13. The symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. The values of the phases shall be as expressed in tables P.44 to P.47.

**Table P.44: Downlink Pilots Set FDPS8 phase values as a multiple of  $\pi$  radians**

| <i>FDPS8</i> |          |

## P.2.6 Filler sets

The numbering and use of these symbol sets are defined in clause 9.4.8.3.7. The amplitude of the symbols is as described in clause 5.13. The symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. The values of the phases shall be as expressed in tables P.48 to P.55.

**Table P.48: Filler Set A FiSA8 phase values as a multiple of  $\pi$  radians**

| <i>FiSA8</i> |          |

## P.2.7 Linearization downlink zeroed set

The numbering and use of this symbol set is defined in clauses 9.4.8.3.8 and P.1.6. The linearization downlink zeroed set is a set of sub-carrier symbols whose magnitude is equal to zero.

## P.2.8 Frequency correction set

The numbering and use of these symbol sets are defined in clauses 9.4.8.3.9 and P.1.7. The Frequency Correction Set contains 60 sub-carrier symbols independent of the number of sub-carriers used. They are denoted FrCS. The amplitude of the non-zero symbols is as described in clause 5.13 for pilots. The rest have zero amplitude.

The values of the phases shall be as expressed in table P.56. For the non-zero sub-channel symbols, the symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians. Those marked 0 in the table shall have zero amplitude.

**Table P.56: Frequency Correction Set phase values as a multiple of  $\pi$  radians (0 indicate zero amplitude)**

| FrCS |          |     |          |     |          |     |          |     |          |
|------|----------|-----|----------|-----|----------|-----|----------|-----|----------|
| F1   | -0,40175 | F13 | 0        | F25 | 0,57364  | F37 | 0,97325  | F49 | 0        |
| F2   | -0,30136 | F14 | 0,77270  | F26 | 0        | F38 | -0,17636 | F50 | -0,10230 |
| F3   | 0,88085  | F15 | 0,17344  | F27 | 0        | F39 | -0,24415 | F51 | 0,04844  |
| F4   | 0        | F16 | 0,60321  | F28 | 0,92344  | F40 | 0        | F52 | -0,77179 |
| F5   | 0        | F17 | -0,65175 | F29 | -0,90175 | F41 | 0        | F53 | 0,72325  |
| F6   | 0,14770  | F18 | 0,94864  | F30 | 0,19864  | F42 | -0,72730 | F54 | -0,92636 |
| F7   | -0,20156 | F19 | -0,36915 | F31 | 0,38085  | F43 | -0,32656 | F55 | 0,50585  |
| F8   | 0,47821  | F20 | 0        | F32 | 0        | F44 | -0,89679 | F56 | 0        |
| F9   | -0,52675 | F21 | 0        | F33 | 0        | F45 | 0,84825  | F57 | 0        |
| F10  | -0,67636 | F22 | -0,60230 | F34 | 0,64770  | F46 | -0,55136 | F58 | 0,52270  |
| F11  | 0,25585  | F23 | 0,54844  | F35 | -0,70156 | F47 | -0,86915 | F59 | 0,42344  |
| F12  | 0        | F24 | 0,72821  | F36 | 0,97821  | F48 | 0        | F60 | -0,64679 |

The FrCS is used in all frequency correction bursts.

The disposition of the phases of the non-zero symbols is such that, together with the intervening sub-carrier pilot symbols (see tables P.23 ... P.26), they generate discrete tones  $\pm 4$  800 Hz,  $\pm 7$  200 Hz and  $\pm 9$  600 Hz away from the transmitter carrier frequency.

## P.2.9 Secondary sync sequence set

The numbering and use of these symbol sets are defined in clauses 9.4.8.3.9 and P.1.7. The Secondary sync Sequence Set contains 8 sub-carrier symbols independent of the number of sub-carriers used. They are denoted SSS.

The SSS are used in all frequency correction bursts and help the MS, together with its surrounding pilots, time synchronize to the symbol, following successful frequency correction.

The values of the phases shall be as expressed in table P.57. For the non-zero sub-channel symbols, the symbol waveform filter independent phases are defined as a multiple of  $\pi$  radians.

**Table P.57: Secondary sync Sequence Set phase values  
as a multiple of  $\pi$  radians**

| SSS |          |

| S'5 | 0,97982  |
| S'6 | -0,45233 |
| S'7 | 0,67411  |
| S'8 | 0,59485  |

---

# Annex Q (normative): Graceful service degradation mode

## Q.1 General

The graceful service degradation mode is intended to provide best effort SDS and status message (short message) services, when an MS has entered into a weak signal situation, where normal speech or data circuit operation in MS traffic mode is no longer available, refer to clause Q.2.

It is outside the scope of the present annex to define which short message services and applications may use the graceful service degradation mode. One example for using the graceful service degradation mode is a callout service that uses the SDS-TL transport service without store and forward functionality.

NOTE 1: The TETRA Association has specified a Callout service.

The present document does not preclude the use of graceful service degradation mode for other services (i.e. circuit mode speech, circuit mode data, and packet data) and applications based on those services. It is outside the scope of the present document to define how to support them.

In the protocol model MLE layer controls entering and leaving the graceful service degradation mode.

NOTE 2: MLE is chosen as the controlling point as it could dynamically control which services are allowed in the graceful service degradation mode, if a network broadcast will be defined in a later version of the present document.

Network layer service entity may indicate which messages are eligible for graceful service degradation mode even in the normal mode and lower layers may apply separate buffers for the graceful service degradation mode messages so that those can by-pass other messages, when MS enters graceful service degradation mode.

---

## Q.2 Procedures

### Q.2.1 Entering graceful service degradation mode

An MS may enter graceful service degradation mode, if serving cell radio link failure occurs as defined in clause 18.3.4.5.3 and if the MS is unable to reselect any neighbour cell in the ranking list whose main carrier path loss parameter, C1 or C2, is greater than zero. The indications "maximum path delay exceeded" and "common channel deallocated" in MLE-REPORT indication shall not invoke graceful service degradation mode.

Upon entering graceful service degradation mode MLE tells to network layer entities in the MLE-BREAK(GSDM) indication which services are allowed during the graceful service degradation mode. MLE shall keep the communication for those services and command lower layer by TL-CONFIGURE request.

### Q.2.2 Operating in graceful service degradation mode

When operating in graceful service degradation mode, an MS shall provide only the specific services that are allowed to use the graceful service degradation mode to the MS user as informed in MLE-BREAK(GSDM) indication primitive.

NOTE 1: It is outside the scope of the present document to define how the MLE knows which services it is permitted to use when MS has entered into the graceful service degradation mode.

When operating in graceful service degradation mode, an MS may not be able to successfully transmit a short message on the uplink. In this case, transmission failure should be indicated to the short message service or application:

- at the TNSDS-SAP with the help of the TNSDS-REPORT primitive as defined in clause 13.3.2.2;
- at the SDS-TL-SAP with the help of the TLSDS-TNSDS-REPORT primitive as defined in clause 29.2.2; and

- at the Concatenation-SAP with the help of the Concatenation-TNSDS-REPORT primitive as defined in clause 29.5.14.3.2.

If transmission failure is detected in graceful service degradation mode, the MS should try to retransmit the uplink short message up to the maximum number of retransmissions (N400). The MS should apply a retransmission algorithm, e.g. wait:

- after initial transmission, the waiting time before first retransmission (T400);
- after first retransmission, the waiting time before second retransmission (T401);
- after second and subsequent retransmissions, the waiting time before other retransmissions (T402).

If an MS finally fails to retransmit an uplink short message in graceful service degradation mode, the MS should locally store the uplink short message as long as it is valid. It is outside the scope of the present document if the storage period of a stored uplink short message:

- is locally defined by a storage timer;
- can be extended by another uplink short message;
- can be defined by other means that are application specific.

NOTE 2: It is an implementation option of the short message service or application to define the storage period, the type and the maximum number of uplink short messages to be stored in graceful service degradation mode.

An MS should try to retransmit an uplink short message in graceful service degradation mode, even if the MS previously failed to retransmit another uplink short message, i.e. an MS should separately apply the retransmission procedure to all uplink short messages.

If an MS is waiting for expiry of timer T400, T401, or T402 in order to retransmit an uplink short message, if the pathloss parameter C1 for the serving cell becomes greater than zero for a short period of time, e.g. less than five seconds, and if the MS has not yet decided to leave graceful service degradation mode as indicated by MLE-BREAK(GSDM) indication, then the MS should stop timer T400, T401, or T402, should instantaneously retransmit the uplink short message and may send some or all valid short messages on the uplink which are either stored or awaiting transmission.

NOTE 3: Implementations may use a modified or different retransmission strategy during graceful service degradation mode than outlined in this clause. The retransmission strategy should prevent overloading of the signalling channel.

### Q.2.3 Criterion for temporary break of service in graceful service degradation mode

When an MS operates in graceful service degradation mode and if the MS is no longer able to reliably decode downlink data for a short period of time for graceful service degradation mode purposes MLE shall indicate that with a MLE-BREAK indication, the MS may remain ready for graceful service degradation mode. During this temporary break of service, the MS shall not send any uplink messages related to the graceful service degradation mode and should suspend timer T400, T401, or T402. When the MS is again able to reliably decode downlink data for graceful service degradation mode purposes as indicated by MLE-BREAK(GSDM) indication, the MS should continue timer T400, T401, or T402 and should continue transmitting or retransmitting uplink short messages. When the MS is permanently unable to reliably decode downlink data for graceful service degradation mode purposes, then the MS shall follow the procedure as defined in clause Q.2.5.

NOTE: It is outside the scope of the present document to define the duration of a temporary break of service in graceful service degradation mode.

## Q.2.4 Criterion for leaving graceful service degradation mode due to service aggradation

An MS shall leave graceful service degradation mode in order to regain full service:

- if the pathloss parameter C1 for the serving cell becomes greater than zero for normal service;
- if the MS selects a neighbour cell the pathloss parameter C1 of which is greater than zero and greater than the pathloss parameter C1 of the serving cell plus FAST\_RESELECT\_HYSTERESIS;
- if the MS selects a cell not contained in the neighbour cell list the pathloss parameter C1 of which is greater than zero and greater than the pathloss parameter C1 of the serving cell plus FAST\_RESELECT\_HYSTERESIS.

When an MS has left graceful service degradation mode and if the MS has regained service as indicated by MLE-RESUME indication, the MS should send all valid short messages on the uplink which are either stored or awaiting transmission or retransmission.

## Q.2.5 Criterion for leaving graceful service degradation mode due to catastrophic service degradation

An MS shall leave graceful service degradation mode due to permanent service unavailability, if the MS is no longer able to reliably decode downlink data for an extended period of time for graceful service degradation mode purposes or if the BS of the serving cell has entered no service mode as defined in clause 19.3.6. MLE indicates that situation to the upper layers with a MLE-CLOSE indication. Thus, the MS invokes the initial cell selection procedure as defined in clause 18.3.4.6.

## Q.2.6 Criterion for starting scanning of neighbour cells in graceful service degradation mode

When operating in graceful service degradation mode, an MS shall continue scanning of neighbour cells as defined in clause 18.3.4.5.2.

## Q.2.7 Criterion for starting scanning of non-neighbour cells in graceful service degradation mode

When operating in graceful service degradation mode for an extended period of time, an MS may start scanning cells not contained in the neighbour cell list. Actual details are out of the scope of the present document.

---

## Q.3 Constants and Timers

This clause lists the graceful service degradation mode constants and timers in the MS. The MS designer shall choose a value from within a given range which shall be used by the MS unless it received a different value when it subscribed to a network.

N400 Maximum number of retransmissions =

- Retransmission not allowed 0;
- Retransmissions allowed: 1 to 10, default = 3.

T400 Waiting time before first retransmission =

- 10 s to 180 s, default = 30 s.

T401 Waiting time before second retransmission =

- 10 s to 180 s, default = 60 s.

T402 Waiting time before other retransmissions =

- 10 s to 180 s, default = 90 s.

---

## Annex R (normative): Subscriber Class Preference levels

### R.1 Introduction

Subscriber class preference levels can be used by operators to create different network layers, e.g.:

- air cells to be used by MSs installed in helicopters and fixed wing airplanes at flying altitude, thus avoiding RF interference on "normal" cells;
- terrestrial cells intended for indoor coverage, providing dedicated coverage (and often small capacity) in a specific building or area;
- "normal" terrestrial cells intended for outdoor coverage;
- underground cells intended to provide (low capacity) services into Underground Transit networks.

---

### R.2 Subscriber Class preference levels

There are four preference levels for subscriber classes:

- 1) Highly Preferred Subscriber Class (HPSC).
- 2) Preferred Subscriber Class (PSC).
- 3) (Basic) Subscriber Class (BSC).
- 4) Unpreferred Subscriber Class (USC).

Subscriber classes 1 and 2 are reserved for HPSC and one of them is used for A2G service as described in annex O. The allocation of the remaining subscriber classes 3-16 (see clauses 16.10.49 and 18.5.22) to the preference levels is out of scope of the present document.

---

## Annex S (informative): Multiple CA cells sharing a channel - interim method

This version of the present document supports sharing of an assigned channel by MSs from multiple DA cells, or by MSs from one DA cell and one CA cell, or by MSs from multiple DA cells and one CA cell. However it does not provide a general method for sharing of an assigned channel by MSs from multiple CA cells. In general, if this facility is supported in a future version of the present document, the CA MSs on the shared channel would need to use some different procedures to support this function fully (for example, when processing SYSINFO PDUs received on a shared channel and when receiving the channel allocation at the end of the call). However, it may be possible for SwMIs to use the following restricted method in the interim without the MSs being aware of the usage.

NOTE 1: It is possible that some MS implementations may include checks that are not compatible with this restricted method.

This is the case of CA cells that have the same MCC, MNC, LA and colour code (and the same static cipher key or common cipher key), and where one of the CA cells is an umbrella cell i.e. a cell whose coverage area fully covers the coverage areas of the other CA cells; this could occur, for example, if there are CA cells that have a sectored coverage area within a CA cell that is nominally circular (and whose radial range is the same as or greater than the radial range of the sectored cells). Then the CA MSs on those cells could be assigned to a phase modulation channel that is conforming relative to the umbrella CA cell's main carrier, with a channel allocation to the umbrella CA cell's main carrier at the end of the call. Thus those CA MSs from the smaller CA cells that have accepted the call on the umbrella channel undergo a forced cell change onto the umbrella CA cell. This cell change is likely to be un-noticed by the CA MSs, since the LA is the same.

NOTE 2: It is possible that some MS implementations may include checks that are not compatible with this method.

Since the umbrella channel is conforming relative to the new CA cell, a non-augmented channel allocation could be used when allocating the umbrella channel to the CA MSs, including the MSs from the smaller CA cells. Therefore this method may be usable for all CA MSs, including those that do not support the augmented channel allocation.

SYSINFO PDUs sent on the umbrella channel would indicate the main carrier of the umbrella CA cell.

The umbrella CA cell and the smaller CA cells would need to use the same "cell identifier CA" values to identify the same CA neighbour cells (including the other CA cells that may send MSs to the umbrella channel) and would need to use the same "cell identifier DA" values to identify the same DA neighbour cells.

When a CA MS has undergone a forced and un-noticed cell change as a result of accepting a channel allocation for the umbrella channel, it will not have its old CA cell on its neighbour cell list but will probably have the new CA cell on its neighbour cell list.

- The MS is likely to receive neighbour cell information for its old CA cell in due course.
- However the MS could continue to monitor or scan its new CA cell, regarding it as a neighbour cell, and could decide to re-select to it if the umbrella CA cell's main carrier happens to have a better RSSI than the assigned umbrella channel. If the SwMI wishes to avoid this, it could send revised "neighbour cell information" on the assigned umbrella channel for the "cell identifier CA" used by the smaller CA cells for the umbrella CA cell, to overwrite the MS's record of the umbrella CA cell as a neighbour and, for example, indicating a carrier number not used locally. (If there are also DA MSs sharing the umbrella channel and using the same cell identifier CA for the umbrella CA cell, the SwMI could then send genuine information about the umbrella CA cell as the local CA cell in the "neighbour cell information for CA" element in the D-NWRK-BROADCAST-DA PDU.)

It is expected that whatever preference caused the MS to select the smaller CA cell in the first place would cause the MS to return to a smaller cell in due course at the end of the call.

## Annex T (informative): Change Requests

The present document includes Change Requests as presented in table T.1.

NOTE: The version number column indicates the version that is used as the baseline for the CR and the next version of the standard is modified as indicated in the CR.

**Table T.1: List of Change Requests**

| No  | CR vers. | Version (see note) | Clauses affected  | Title   | CR Status           |
|-----|----------|--------------------|---|---|---------------------|
| 001 | APP      | V2.1.1             | 28.4.4.1, 28.4.4.2, 28.4.4.3, 28.4.5.2  | Access point name index size  | EPT Approved 2000   |
| 002 | APPi     | V2.3.2             | 17.3.5, 17.3.6, 17.3.9, 18.2.4, 18.2.8, 20.2.4, 20.3.4, 20.3.5.1, 22.1.2, 22.2.2.3, 22.2.2.5, 22.2.2.7, 22.3.3.2.2, 22.3.3.2.7, 28.2.4.7, 28.2.6.2 and clause A.1 | READY timer enhancement   | EPT approved 011121 |
| 003 | APP      | V2.3.1             | 29.5.4.2  | Text Character Encoding and Packing for 7, 8 and 16-bit Alphabet                    | EPT approved 010305 |
| 004 | APP      | V2.3.1             | 29.4.3.9  | Error in see note reference   | EPT approved 010305 |
| 005 | APP      | V2.3.1             | 16.10.5 Table 167   | Clarification of Concurrent Channel in Class of MS                                  | EPT approved 010419 |
| 006 | APP      | V2.3.1             | 14.4.2 Figure 22  | Acceptance of D_INFO in CC WAIT state   | EPT approved 010305 |
| 007 | APP      | V2.3.1             | 21.4.4.1  | Additional bit required for Security Information ("GCK Supported") for use in 392-7 | EPT approved 010419 |
| 008 | APP      | V2.3.1             | 28.2.4.5, 28.2.4.8, Figure 184 and Table 365  | Migration of Packet Data Mobile   | EPT approved 010419 |
| 009 | REJ      | V2.3.1             | 28.2.5a   | Mismatch of subscriber class  | Rejected            |
| 010 | APPi2    | V2.3.1             | 28.3.6, 28.4.1, 28.4.4.3, 28.4.5.10, 28.4.5.38 and 28.4.5.45  | Correction of typographical errors and minor omissions                              | EPT approved 010419 |
| 011 | APPi     | V2.3.2             | 28.2.4.4, 28.2.4.7, 28.4.4.9, 28.5  | Use of Immediate service change element on downlink                                 | EPT approved 011121 |
| 012 | REJ      | V2.3.1             | 16.4, 16.9, 16.10   | SwMI Capabilities   | Withdrawn           |
| 013 | REJ      | V2.3.1             | 21.4.4.1  | Additional bit required for Security Information ("Short GCK-VN") for use in 392-7  | Rejected            |
| 014 | REJ      | V2.3.1             | 14.5.6.2  | PDU Priority for U-INFO   | Rejected            |
| 015 | Comb     | V2.3.1             | 11.3.4, 14.8.18   | New additional disconnect cause   | Combined with CR021 |
