

ETSI TS 101 376-5-3 V3.2.1 (2011-02)

Technical Specification

**GEO-Mobile Radio Interface Specifications (Release 3);
Third Generation Satellite Packet Radio Service;
Part 5: Radio interface physical layer specifications;
Sub-part 3: Channel Coding;
GMR-1 3G 45.003**

Reference

RTS/SES-00315-5-3

Keywords3G, coding, GMPRS, GMR, GPRS, GSM, GSO,
interface, MES, mobile, MSS, radio, satellite**ETSI**

Foreword.....	11
Introduction	12
1 Scope	14
2 References	14
2.1 Normative references	14
2.2 Informative references.....	15
3 Definitions and abbreviations.....	15
3.1 Definitions	15
3.2 Abbreviations	15
4 General	15
4.1 General organization	15
4.2 Naming convention	15
4.3 Parity checking.....	15
4.4 Convolutional coding	16
4.4.1 Convolutional encoding (all channels except TCH3)	16
4.4.1.1 Rate 1/2 convolutional code.....	16
4.4.1.2 Rate 1/4 convolutional code.....	16
4.4.1.3 Rate 1/3 convolutional code.....	16
4.4.1.4 Rate 1/5 convolutional code.....	16
4.4.1.5 Rate 1/2 convolutional code (constraint length 9).....	17
4.4.2 Convolutional encoding for TCH3	17
4.4.3 Viterbi decoder for TCH3.....	17
4.4.4 Convolutional encoding for Extended PUI.....	17
4.4.5 Tail Biting Rate 1/2 convolutional code, constraint length 5	18
4.4.6 Tail Biting Rate 1/2 convolutional code, constraint length 9	18
4.4.7 Tail Biting Rate 1/3 convolutional code, constraint length 5	18
4.4.8 Rate 1/4 Constraint length 9 Convolutional Encoder	19
4.4.9 Rate 1/3 Constraint length 9 Convolutional Encoder	19
4.5 Puncturing and repetition	20
4.6 Golay encoding	24
4.7 Reed-Solomon encoding	24
4.7.1 Encoder.....	24
4.7.2 Galois field arithmetics	24
4.7.3 Encoder feedback register operation.....	24
4.8 Interleaving.....	24
4.8.1 Intraburst interleaving.....	25
4.8.2 Interburst interleaving.....	25
4.9 Scrambling	25
4.10 LDPC Codes.....	25
4.10.1 General Operations	25
4.10.2 LDPC Encoding.....	26
4.10.3 Bit Interleaver	28
4.11 Turbo codes	28
4.11.1 Turbo encoder.....	28
4.11.2 Turbo Code Termination	29
4.11.3 Turbo code internal interleaver.....	30
4.11.4 Turbo Code Puncturing.....	32
5 Traffic channels.....	35
5.1 Traffic channel-3 (TCH3).....	35
5.1.1 Channel coding	35
5.1.2 Interleaving	35
5.1.3 Scrambling, multiplexing, and encryption.....	36

5.2	Traffic channel-6 (TCH6).....	36
5.2.1	Channel coding	36
5.2.1.1	Coding for 2,4 kbps fax.....	36
5.2.1.2	Coding for 2,4 kbps data	36
5.2.1.3	Coding for 4,8 kbps fax/data	36
5.2.2	Interleaving	36
5.2.3	Scrambling, multiplexing, and encryption	36
5.3	Traffic channel-9 (TCH9).....	36
5.3.1	Channel coding	36
5.3.1.1	Coding for 2,4 kbps fax.....	36
5.3.1.2	Coding for 4,8 kbps fax.....	36
5.3.1.3	Coding for 9,6 kbps fax/data	36
5.3.2	Interleaving	36
5.3.3	Scrambling, multiplexing, and encryption	36
6	Control channels.....	37
6.1	Broadcast Control CHannel (BCCH)	37
6.1.1	Channel coding	37
6.1.2	Interleaving	37
6.1.3	Scrambling and multiplexing	37
6.1a	Broadcast Control Channel over DC12 burst	37
6.1a.1	Channel coding	37
6.1a.2	Interleaving	37
6.1a.3	Scrambling and multiplexing	37
6.2	Paging CHannel (PCH)	37
6.2.1	Channel coding	37
6.2.2	Interleaving	37
6.2.3	Scrambling and multiplexing	37
6.2a	Paging Channel over DC12 burst	38
6.2a.1	Channel coding	38
6.2a.2	Interleaving	38
6.2a.3	Scrambling and multiplexing	38
6.3	Access Grant CHannel (AGCH)	38
6.3.1	Channel coding	38
6.3.2	Interleaving	38
6.3a	Access Grant Channel over DC12 burst.....	38
6.3a.1	Channel coding	38
6.3a.2	Interleaving	38
6.3a.3	Scrambling and multiplexing	38
6.4	Broadcast Alerting CHannel (BACH)	38
6.4.1	Channel coding	39
6.5	Random Access CHannel (RACH)	39
6.5.1	Channel coding	39
6.5.2	Interleaving	39
6.5.3	Scrambling and multiplexing	39
6.5a	Random Access Channel3 (RACH3)	39
6.5a.1	Channel coding	39
6.5a.2	Interleaving	39
6.5a.3	Scrambling and multiplexing	39
6.6	Cell Broadcast CHannel (CBCH).....	39
6.6.1	Channel coding	39
6.6.2	Interleaving	40
6.7	Standalone Dedicated Control CHannel (SDCCH).....	40
6.7.1	Channel coding	40
6.7.2	Interleaving	40
6.7.3	Scrambling, multiplexing, and encryption	40
6.8	Slow Associated Control CHannel (SACCH)	40
6.8.1	Channel coding	40
6.8.2	Interleaving	40
6.9	Fast Associated Control CHannel-3 (FACCH3)	40
6.9.1	Channel coding	40
6.9.2	Interleaving	40

6.9.3	Scrambling, multiplexing, and encryption	40
6.10	Fast Associated Control CHannel-6 (FACCH6)	40
6.10.1	Channel coding	41
6.10.2	Interleaving	41
6.10.3	Scrambling, multiplexing, and encryption	41
6.11	Fast Associated Control CHannel-9 (FACCH9)	41
6.11.1	Channel coding	41
6.11.2	Interleaving	41
6.11.3	Scrambling, multiplexing, and encryption	41
6.12	Terminal-to-terminal Associated Control CHannel (TACCH).....	41
6.12.1	TACCH channel coding.....	41
6.12.2	Interleaving	41
6.12.3	Scrambling and multiplexing	41
6.12.4	PHYSical (PHY) header for TACCH.....	41
6.13	GPS Broadcast CHannel (GBCH).....	41
6.13.1	Channel coding	42
6.13.2	Interleaving	42
6.13.3	Scrambling and multiplexing	42
6.13a	GPS Broadcast Channel3 (GBCH3).....	42
6.13a.1	Channel coding	42
6.13a.2	Interleaving	42
6.13a.3	Scrambling and multiplexing	42
6.14	ULMAP	42
6.14.1	ULMAP for PNB3 (5,3)/downlink	42
6.14.1.1	Channel coding	42
6.14.1.2	Interleaving	42
6.14.1.3	Scrambling and multiplexing	42
6.14.1.4	Repetition.....	43
6.14.2	ULMAP for PNB3(5,12)/downlink	43
6.14.2.1	Channel coding	43
6.14.2.2	Interleaving	43
6.14.2.3	Scrambling and multiplexing	43
6.14.2.4	Repetition.....	43
6.14.3	ULMAP for PNB3 (10,3)	43
6.14.3.1	Channel coding	43
6.14.3.2	Interleaving	43
6.14.3.3	Scrambling and multiplexing	43
6.14.3.4	Repetition.....	44
7	Logical channel multiplexing	44
7.1	SACCH multiplexing	44
7.2	Status field.....	44
7.2.1	Power control field.....	44
7.2.1.1	DCH (Dedicated Channel) Power control field.....	44
7.2.2	Comfort noise field	45
7.2.3	Link Quality Indicator field	45
7.3	Status field with NTN bursts	45
7.3.1	Status field with NT6 and NT9 bursts	45
7.3.2	Status field with NT3 bursts	45
7.3.2.1	Status field with NT3 bursts for encoded speech	45
7.3.2.2	Status field with NT3 bursts for FACCH	45
7.3.3	Status field with Keep-Alive Bursts (KAB)	45
7.4	Status field with DCH bursts	45
7.4.1	Status field with PNB3(1,3), PNB3(1,6), and PNB3(1,8).....	45
7.4.2	Status field with KAB3(1,3),	46
7.4.3	Status field with KAB3(1,6)	46
7.4.4	Status field with KAB3(1,8)	46
8	Encryption	46
9	Packet Switched Channels.....	46
9.1	Packet Data Traffic Channels	46
9.1.1	Public Information (PUI).....	47

9.1.1a	Extended PUI (A/Gb mode only)	47
9.1.1b	Public Information (PUI3)	47
9.1.1b.1	PUI3 for PNB3(5,3)/downlink and PNB3 (5,12)/downlink	47
9.1.1b.1.1	Channel coding	47
9.1.1b.1.2	Interleaving	47
9.1.1b.1.3	Scrambling and multiplexing	47
9.1.1b.1.4	Repetition	47
9.1.1b.2	PUI3 for PNB3(10,3)	47
9.1.1b.2.1	Channel coding	48
9.1.1b.2.2	Interleaving	48
9.1.1b.2.3	Scrambling and multiplexing	48
9.1.1b.2.4	Repetition	48
9.1.1b.3	PUI3 for PNB3(2,6)	48
9.1.1b.3.1	Channel coding	48
9.1.1b.3.2	Interleaving	48
9.1.1b.3.3	Scrambling and multiplexing	48
9.1.1b.3.4	Repetition	48
9.1.2	Void	49
9.1.3	Packet Normal Burst PNB(4,3)	49
9.1.3.1	Rate 1/2 convolutional coding	49
9.1.3.2	Rate 5/8 convolutional coding	49
9.1.3.3	Rate 3/4 convolutional coding	49
9.1.3.4	Interleaving	50
9.1.3.5	Scrambling, multiplexing, and encryption	50
9.1.4	Packet Normal Burst PNB(5,3)	50
9.1.4.1	Rate 1/2 convolutional coding	50
9.1.4.2	Rate 5/8 convolutional coding	50
9.1.4.3	Rate 3/4 convolutional coding	51
9.1.4.4	Interleaving	51
9.1.4.5	Scrambling, multiplexing, and encryption	51
9.1.5	Void	51
9.1.6	Packet Normal Burst PNB(1,6)	51
9.1.6.1	Rate 3/5 convolutional coding	51
9.1.6.2	Rate 7/10 convolutional coding	52
9.1.6.3	Rate 4/5 convolutional coding	52
9.1.6.4	Interleaving	52
9.1.6.5	Scrambling, multiplexing, and encryption	52
9.1.7	Packet Normal Burst PNB(2,6)	52
9.1.7.1	Rate 3/5 convolutional coding	52
9.1.7.2	Rate 7/10 convolutional coding	53
9.1.7.3	Rate 4/5 convolutional coding	53
9.1.7.4	Interleaving	53
9.1.7.5	Scrambling, multiplexing, and encryption	53
9.1.8	Packet Normal Burst PNB2(5,12)	53
9.1.8.1	$\pi/4$ QPSK Rate 0,497 LDPC Coding	54
9.1.8.2	$\pi/4$ QPSK Rate 0,508 LDPC Coding	54
9.1.8.3	$\pi/4$ QPSK Rate 0,667 LDPC Coding	54
9.1.8.4	$\pi/4$ QPSK Rate 0,681 LDPC Coding	54
9.1.8.5	$\pi/4$ QPSK Rate 0,800 LDPC Coding	55
9.1.8.6	$\pi/4$ QPSK Rate 0,818 LDPC Coding	55
9.1.8.7	$\pi/4$ QPSK Rate 0,899 LDPC Coding	55
9.1.8.8	$\pi/4$ QPSK Rate 0,919 LDPC Coding	55
9.1.8.9	16APSK Rate 0,667 LDPC Coding	56
9.1.8.10	16APSK Rate 0,681 LDPC Coding	56
9.1.8.11	16APSK Rate 0,800 LDPC Coding	56
9.1.8.12	16APSK Rate 0,818 LDPC Coding	56
9.1.8.13	16APSK Rate 0,900 LDPC Coding	57
9.1.8.14	32APSK Rate 0,765 LDPC Coding	57
9.1.8.15	32APSK Rate 0,818 LDPC Coding	57
9.1.8.16	Interleaving	57
9.1.8.17	Scrambling, multiplexing, and encryption	57

9.1.9	LDPC Coded Packet Normal Burst PNB2(5,3).....	57
9.1.9.1	$\pi/4$ QPSK Rate 0,509 LDPC Coding.....	58
9.1.9.2	$\pi/4$ QPSK Rate 0,660 LDPC Coding.....	58
9.1.9.3	$\pi/4$ QPSK Rate 0,793 LDPC Coding.....	58
9.1.9.4	$\pi/4$ QPSK Rate 0,894 LDPC Coding.....	58
9.1.9.5	16APSK Rate 0,664 LDPC Coding.....	59
9.1.9.6	16APSK Rate 0,797 LDPC Coding.....	59
9.1.9.7	16APSK Rate 0,898 LDPC Coding.....	59
9.1.9.8	32APSK Rate 0,748 LDPC Coding.....	59
9.1.9.8a	32APSK Rate 0,798 LDPC Coding.....	60
9.1.9.9	Interleaving.....	60
9.1.9.10	Scrambling, multiplexing, and encryption.....	60
9.1.10	Packet Normal Burst PNB3(1,3).....	60
9.1.10.1	PNB3(1,3) 2,45 kbps speech.....	60
9.1.10.1.1	Channel coding.....	60
9.1.10.1.2	Interleaving.....	61
9.1.10.1.3	Scrambling.....	61
9.1.10.2	PNB3(1,3) 2,6 kbps data over DCH (Dedicated Channel).....	61
9.1.10.2.1	Channel coding.....	61
9.1.10.2.2	Interleaving.....	61
9.1.10.2.3	Scrambling.....	61
9.1.10.3	PNB3(1,3) 4 kbps Speech.....	61
9.1.10.3.1	Channel coding.....	61
9.1.10.3.2	Interleaving.....	62
9.1.10.3.3	Scrambling.....	62
9.1.10.4	PNB3(1,3) 4 kbps data over DCH (Dedicated Channel).....	62
9.1.10.4.1	Channel coding.....	62
9.1.10.4.2	Interleaving.....	62
9.1.10.4.3	Scrambling.....	62
9.1.11	Packet Normal Burst PNB3(1,6).....	62
9.1.11.1	PNB3(1,6) 2,45 kbps Speech.....	62
9.1.11.1.1	Channel coding.....	63
9.1.11.1.2	Interleaving.....	63
9.1.11.1.3	Scrambling.....	63
9.1.11.2	PNB3(1,6) 2,6 kbps Data over DCH (Dedicated channel).....	63
9.1.11.2.1	Channel coding.....	63
9.1.11.2.2	Interleaving.....	63
9.1.11.2.3	Scrambling.....	63
9.1.11.3	PNB3(1,6) 4 kbps Speech.....	64
9.1.11.3.1	Channel coding.....	64
9.1.11.3.2	Interleaving.....	64
9.1.11.3.3	Scrambling.....	64
9.1.11.4	PNB3(1,6) 4 kbps Data over DCH (Dedicated Channel).....	64
9.1.11.4.1	Channel coding.....	64
9.1.11.4.2	Interleaving.....	65
9.1.11.4.3	Scrambling.....	65
9.1.12	Packet Normal Burst PNB3(1,8).....	65
9.1.12.1	PNB3(1,8) 4 kbps speech.....	65
9.1.12.1.1	Channel coding.....	65
9.1.12.1.2	Interleaving.....	65
9.1.12.1.3	Scrambling.....	65
9.1.12.2	PNB3(1,8) 4 kbps data over DCH(Dedicated Channel).....	65
9.1.12.2.1	Channel coding.....	66
9.1.12.2.2	Interleaving.....	66
9.1.12.2.3	Scrambling.....	66
9.1.13	Packet Normal Burst PNB3(2,6)/uplink.....	66
9.1.13.1	Rate 3/5 Turbo coding.....	66
9.1.13.2	Rate 7/10 Turbo coding.....	66
9.1.13.3	Rate 4/5 Turbo coding.....	67
9.1.13.4	Interleaving.....	67
9.1.13.5	Scrambling, multiplexing, and encryption.....	67

9.1.14	Packet Normal Burst PNB3(2,6)/downlink	67
9.1.14.1	Rate 3/5 Turbo coding.....	67
9.1.14.2	Rate 7/10 Turbo coding.....	67
9.1.14.3	Rate 4/5 Turbo coding.....	68
9.1.14.4	Interleaving	68
9.1.14.5	Scrambling, multiplexing, and encryption	68
9.1.15	PNB3 (5,3) burst.....	68
9.1.15.1	$\pi/4$ QPSK PNB3(5,3) Rate 1/2	68
9.1.15.1.1	Channel coding.....	68
9.1.15.1.2	Interleaving.....	68
9.1.15.1.3	Scrambling.....	69
9.1.15.2	$\pi/4$ QPSK PNB3(5,3) Rate 5/8	69
9.1.15.2.1	Channel coding.....	69
9.1.15.2.2	Interleaving.....	69
9.1.15.2.3	Scrambling.....	69
9.1.15.3	$\pi/4$ QPSK PNB3(5,3) Rate 3/4	69
9.1.15.3.1	Channel Coding.....	69
9.1.15.3.2	Interleaving.....	69
9.1.15.3.3	Scrambling.....	69
9.1.15.4	$\pi/4$ QPSK PNB3(5,3) Rate 5/6	70
9.1.15.4.1	Channel coding.....	70
9.1.15.4.2	Interleaving.....	70
9.1.15.4.3	Scrambling.....	70
9.1.15.5	16APSK PNB3(5,3) Rate 2/3.....	70
9.1.15.5.1	Channel coding.....	70
9.1.15.5.2	Interleaving.....	70
9.1.15.5.3	Scrambling.....	70
9.1.16	PNB3 (5,3) burst carrying ULMAP.....	71
9.1.16.1	$\pi/4$ QPSK PNB3(5,3) Rate 1/2 burst carrying ULMAP	71
9.1.16.1.1	Channel coding.....	71
9.1.16.1.2	Interleaving.....	71
9.1.16.1.3	Scrambling.....	71
9.1.16.2	$\pi/4$ QPSK PNB3(5,3) Rate 5/8 carrying ULMAP	71
9.1.16.2.1	Channel coding.....	71
9.1.16.2.2	Interleaving.....	71
9.1.16.2.3	Scrambling.....	71
9.1.16.3	$\pi/4$ QPSK PNB3(5,3) Rate 3/4 carrying ULMAP	72
9.1.16.3.1	Channel Coding.....	72
9.1.16.3.2	Interleaving.....	72
9.1.16.3.3	Scrambling.....	72
9.1.16.4	$\pi/4$ QPSK PNB3(5,3) Rate 5/6 carrying ULMAP	72
9.1.16.4.1	Channel coding.....	72
9.1.16.4.2	Interleaving.....	72
9.1.16.4.3	Scrambling.....	72
9.1.16.5	16APSK PNB3(5,3) carrying ULMAP Rate 2/3.....	73
9.1.16.5.1	Channel coding.....	73
9.1.16.5.2	Interleaving.....	73
9.1.16.5.3	Scrambling.....	73
9.1.17	PNB3 (5,12) burst.....	73
9.1.17.1	$\pi/4$ QPSK PNB3(5,12) burst Rate 1/2.....	73
9.1.17.1.1	Channel coding.....	73
9.1.17.1.2	Interleaving.....	73
9.1.17.1.3	Scrambling.....	74
9.1.17.2	$\pi/4$ QPSK PNB3(5,12) burst Rate 5/8.....	74
9.1.17.2.1	Channel coding.....	74
9.1.17.2.2	Interleaving.....	74
9.1.17.2.3	Scrambling.....	74
9.1.17.3	$\pi/4$ QPSK PNB35,12) burst Rate 3/4.....	74
9.1.17.3.1	Channel coding.....	74
9.1.17.3.2	Interleaving.....	74
9.1.17.3.3	Scrambling.....	74

9.1.17.4	$\pi/4$ QPSK PNB3(5,12) burst Rate 5/6.....	75
9.1.17.4.1	Channel coding.....	75
9.1.17.4.2	Interleaving.....	75
9.1.17.4.3	Scrambling.....	75
9.1.17.5	16APSK PNB3(5,12) burst Rate 2/3.....	75
9.1.17.5.1	Channel coding.....	75
9.1.17.5.2	Interleaving.....	75

Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "*Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards*", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://webapp.etsi.org/IPR/home.asp>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Satellite Earth Stations and Systems (SES).

The contents of the present document are subject to continuing work within TC-SES and may change following formal TC-SES approval. Should TC-SES modify the contents of the present document it will then be republished by ETSI with an identifying change of release date and an increase in version number as follows:

Version 3.m.n

where:

- the third digit (n) is incremented when editorial only changes have been incorporated in the specification;
- the second digit (m) is incremented for all other types of changes, i.e. technical enhancements, corrections, updates, etc.

The present document is part 5, sub-part 3 of a multi-part deliverable covering the GEO-Mobile Radio Interface Specifications (Release 3); Third Generation Satellite Packet Radio Service, as identified below:

Part 1: "General specifications";

Part 2: "Service specifications";

Part 3: "Network specifications";

Part 4: "Radio interface protocol specifications";

Part 5: "Radio interface physical layer specifications":

Sub-part 1: "Physical Layer on the Radio Path: General Description";

Sub-part 2: "Multiplexing and Multiple Access; Stage 2 Service Description";

Sub-part 3: "Channel Coding";

Sub-part 4: "Modulation";

Sub-part 5: "Radio Transmission and Reception";

Sub-part 6: "Radio Subsystem Link Control";

Sub-part 7: "Radio Subsystem Synchronization";

Part 6: "Speech coding specifications";

Part 7: "Terminal adaptor specifications".

Introduction

GMR stands for GEO (Geostationary Earth Orbit) Mobile Radio interface, which is used for Mobile Satellite Services (MSS) utilizing geostationary satellite(s). GMR is derived from the terrestrial digital cellular standard GSM and supports access to GSM core networks.

The present document is part of the GMR Release 3 specifications. Release 3 specifications are identified in the title and can also be identified by the version number:

- Release 1 specifications have a GMR 1 prefix in the title and a version number starting with "1" (V1.x.x).
- Release 2 specifications have a GMPRS 1 prefix in the title and a version number starting with "2" (V2.x.x).
- Release 3 specifications have a GMR-1 3G prefix in the title and a version number starting with "3" (V3.x.x).

The GMR release 1 specifications introduce the GEO-Mobile Radio interface specifications for circuit mode Mobile Satellite Services (MSS) utilizing geostationary satellite(s). GMR release 1 is derived from the terrestrial digital cellular standard GSM (phase 2) and it supports access to GSM core networks.

The GMR release 2 specifications add packet mode services to GMR release 1. The GMR release 2 specifications introduce the GEO-Mobile Packet Radio Service (GMPRS). GMPRS is derived from the terrestrial digital cellular standard GPRS (included in GSM Phase 2+) and it supports access to GSM/GPRS core networks.

The GMR release 3 specifications evolve packet mode services of GMR release 2 to 3rd generation UMTS compatible services. The GMR release 3 specifications introduce the GEO-Mobile Radio Third Generation (GMR-1 3G) service. Where applicable, GMR-1 3G is derived from the terrestrial digital cellular standard 3GPP and it supports access to 3GPP core networks.

Due to the differences between terrestrial and satellite channels, some modifications to the GSM or 3GPP standard are necessary. Some GSM and 3GPP specifications are directly applicable, whereas others are applicable with modifications. Similarly, some GSM and 3GPP specifications do not apply, while some GMR specifications have no corresponding GSM or 3GPP specification.

Since GMR is derived from GSM and 3GPP, the organization of the GMR specifications closely follows that of GSM or 3GPP as appropriate. The GMR numbers have been designed to correspond to the GSM and 3GPP numbering system. All GMR specifications are allocated a unique GMR number. This GMR number has a different prefix for Release 2 and Release 3 specifications as follows:

- Release 1: GMR n xx.zyy.
- Release 2: GMPRS n xx.zyy.
- Release 3: GMR-1 3G xx.zyy.

where:

- xx.0yy ($z = 0$) is used for GMR specifications that have a corresponding GSM or 3GPP specification. In this case, the numbers xx and yy correspond to the GSM or 3GPP numbering scheme.
- xx.2yy ($z = 2$) is used for GMR specifications that do not correspond to a GSM or 3GPP specification. In this case, only the number xx corresponds to the GSM or 3GPP numbering scheme and the number yy is allocated by GMR.
- n denotes the first ($n = 1$) or second ($n = 2$) family of GMR specifications.

A GMR system is defined by the combination of a family of GMR specifications and GSM and 3GPP specifications as follows:

- If a GMR specification exists it takes precedence over the corresponding GSM or 3GPP specification (if any). This precedence rule applies to any references in the corresponding GSM or 3GPP specifications.

NOTE: Any references to GSM or 3GPP specifications within the GMR specifications are not subject to this precedence rule. For example, a GMR specification may contain specific references to the corresponding GSM or 3GPP specification.

- If a GMR specification does not exist, the corresponding GSM or 3GPP specification may or may not apply. The applicability of the GSM and 3GPP specifications is defined in GMR-1 3G 41.201 [2].

1 Scope

The present document specifies the data blocks given to the encryption unit and the mapping onto the free bits of a burst. It includes the specifications for encoding, reordering, interleaving, and detailed mapping onto the burst. It does not specify the channel decoding method. The definition is given for each kind of logical channel, starting with the data provided to the channel encoder by the speech coder, the data terminal equipment, or the controller of the Mobile Earth Station (MES).

2 References

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the reference document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at <http://docbox.etsi.org/Reference>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication ETSI cannot guarantee their long term validity.

2.1 Normative references

The following referenced documents are necessary for the application of the present document.

In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document *in the same Release as the present document*.

- [1] GMPRS-1 01.004 (ETSI TS 101 376-1-1): "GEO-Mobile Radio Interface Specifications (Release 2); General Packet Radio Service (GMPRS); Part 1: General specifications; Sub-part 1: Abbreviations and acronyms".

NOTE: This is a reference to a GMR-1 Release 2 specification. See the introduction for more details.

- [2] GMR-1 3G 41.201 (ETSI TS 101 376-1-2): "GEO-Mobile Radio Interface Specifications (Release 3); Third Generation Satellite Packet Radio Service; Part 1: General specifications; Sub-part 2: Introduction to the GMR-1 family".

- [3] GMR-1 05.003: (ETSI TS 101 376-5-3): "GEO-Mobile Radio Interface Specifications; Part 5: Radio interface physical layer specifications; Sub-part 3: Channel Coding".

NOTE: This is a reference to a GMR-1 Release 1 specification. See the introduction for more details.

- [4] GMR-1 3G 44.008 (ETSI TS 101 376-4-8): "GEO-Mobile Radio Interface Specifications (Release 3); Third Generation Satellite Packet Radio Service; Part 4: Radio interface protocol specifications; Sub-part 8: Mobile Radio Interface Layer 3 Specifications".

- [5] GMR-1 3G 44.060 (ETSI TS 101 376-4-12): "GEO-Mobile Radio Interface Specifications (Release 3); Third Generation Satellite Packet Radio Service; Part 4: Radio interface protocol specifications; Sub-part 12: Mobile Earth Station (MES) - Base Station System (BSS) interface; Radio Link Control/Medium Access Control (RLC/MAC) protocol".

- [6] GMR-1 3G 45.010 (ETSI TS 101 376-5-7): "GEO-Mobile Radio Interface Specifications (Release 3); Third Generation Satellite Packet Radio Service; Part 5: Radio interface physical layer specifications; Sub-part 7: Radio Subsystem Synchronization".

2.2 Informative references

The following referenced documents are not necessary for the application of the present document but they assist the user with regard to a particular subject area.

Not applicable.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in GMR-1 3G 41.201 [2] apply.

3.2 Abbreviations

For the purposes of the present document, the abbreviations given in GMPRS-1 01.004 [1] apply.

4 General

4.1 General organization

Same as clause 4.1 in GMR-1 05.003 [3].

4.2 Naming convention

Same as clause 4.2 in GMR-1 05.003 [3].

Table 4.1: Void

4.3 Parity checking

Same as clause 4.3 in GMR-1 05.003 [3], except table 4.2. The additional 3-bit CRC polynomial and 5-bit CRC polynomials are given by:

$$g_3(D) = 1 + D + D^3$$

$$g_5(D) = 1 + D + D^2 + D^3 + D^5$$

Table 4.2 indicates the CRC polynomials used in GMR-1 channels.

Table 4.2: CRC polynomials used in GMR-1

Channel	$g_3(D)$	$g_5(D)$	$g_8(D)$	$g_{12}(D)$	$g_{16}(D)$
BCCH					X
PCH					X
AGCH					X
RACH			X	X	
RACH3			X		
CBCH					X
SDCCH					X
SACCH					X
FACCH3					X
FACCH6					X
FACCH9					X
TACCH					X

PDCH			X		X
PDCH3			X		X
PRACH			X		
PRACH3			X		
Downlink PDCH (5,12) Extended PUI			X		
ULMAP	X				
PUI3	x				
DCH3		X			

When the CRC parity is generated against the turbo coded PDCH3, all initial CRC shift register element shall be set to logical one. Otherwise, all initial CRC shift register elements shall be set to logical zero.

4.4 Convolutional coding

4.4.1 Convolutional encoding (all channels except TCH3)

Same as clause 4.4.1 in GMR-1 05.003 [3] with the following additions.

4.4.1.1 Rate 1/2 convolutional code

Same as clause 4.4.1.1 in GMR-1 05.003 [3].

4.4.1.2 Rate 1/4 convolutional code

Same as clause 4.4.1.2 in GMR-1 05.003 [3].

4.4.1.3 Rate 1/3 convolutional code

Same as clause 4.4.1.3 in GMR-1 05.003 [3].

4.4.1.4 Rate 1/5 convolutional code

Same as clause 4.4.1.4 in GMR-1 05.003 [3].

4.4.1.5 Rate 1/2 convolutional code (constraint length 9)

The Rate 1/2 convolutional code of constraint length 9 is defined by the following generator polynomials:

$$g_0(D) = 1 + D^2 + D^3 + D^4 + D^8;$$

$$g_1(D) = 1 + D + D^2 + D^3 + D^5 + D^7 + D^8.$$

The input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded is first extended with tail bits so that $u(k) = 0$ for $k = K, K + 1, \dots, K + 7$. The coded bits are then defined by the following set of linear equations:

$$\text{For } k = 0, 1, \dots, K + 7;$$

$$c(2k) = u(k) \oplus u(k-2) \oplus u(k-3) \oplus u(k-4) \oplus u(k-8);$$

$$c(2k + 1) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-3) \oplus u(k-5) \oplus u(k-7) \oplus u(k-8).$$

This results in a block of coded bits $\{c(0), c(1), c(2), \dots, c(2K + 15)\}$.

4.4.2 Convolutional encoding for TCH3

Same as clause 4.4.2 in GMR-1 05.003 [3].

4.4.3 Viterbi decoder for TCH3

Same as clause 4.4.3 in GMR-1 05.003 [3].

4.4.4 Convolutional encoding for Extended PUI

Same as clause 4.4.2 in GMR-1 05.003 [3], except that a rate 1/4 convolutional code of constraint length 6 is used. The code is defined by the following generator polynomials:

$$g_0(D) = 1 + D^2 + D^5$$

$$g_1(D) = 1 + D^2 + D^3 + D^5$$

$$g_2(D) = 1 + D + D^3 + D^4 + D^5$$

$$g_3(D) = 1 + D + D^2 + D^3 + D^4 + D^5$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-5)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; bit $u(K-1)$ is placed in the register D1 and bit $u(K-6)$ is placed in the register D5. The coded bits are then defined by the following set of linear equation:

$$\text{For } k = 0, 1, \dots, K-1$$

$$c(4k) = u(k) \oplus u(k-2) \oplus u(k-5)$$

$$c(4k + 1) = u(k) \oplus u(k-2) \oplus u(k-3) \oplus u(k-5)$$

$$c(4k + 2) = u(k) \oplus u(k-1) \oplus u(k-3) \oplus u(k-4) \oplus u(k-5)$$

$$c(4k + 3) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-3) \oplus u(k-4) \oplus u(k-5)$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(4K-1)\}$.

4.4.5 Tail Biting Rate 1/2 convolutional code, constraint length 5

The Rate 1/2 convolutional code of constraint length 5 is defined by the following generator polynomials:

$$g_0(D) = 1 + D^3 + D^4;$$

$$g_1(D) = 1 + D + D^2 + D^4.$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-4)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; bit $u(K-1)$ is placed in the register D1 and bit $u(K-4)$ is placed in the register D4. The coded bits are then defined by the following set of linear equation:

For $k = 0, 1, \dots, K-1$

$$c(2k) = u(k) \oplus u(k-3) \oplus u(k-4)$$

$$c(2k + 1) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-4)$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(2K-1)\}$.

4.4.6 Tail Biting Rate 1/2 convolutional code, constraint length 9

The Rate 1/2 convolutional code of constraint length 9 is defined by the following generator polynomials:

$$g_0(D) = 1 + D^2 + D^3 + D^4 + D^8;$$

$$g_1(D) = 1 + D + D^2 + D^3 + D^5 + D^7 + D^8.$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-8)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; bit $u(K-1)$ is placed in the register D1 and bit $u(K-8)$ is placed in the register D8. The coded bits are then defined by the following set of linear equation:

For $k = 0, 1, \dots, K-1$

$$c(2k) = u(k) \oplus u(k-2) \oplus u(k-3) \oplus u(k-4) \oplus u(k-8)$$

$$c(2k + 1) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-3) \oplus u(k-5) \oplus u(k-7) \oplus u(k-8)$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(2K-1)\}$.

4.4.7 Tail Biting Rate 1/3 convolutional code, constraint length 5

This code is defined by the following generator polynomials:

$$g_0(D) = 1 + D^2 + D^4;$$

$$g_1(D) = 1 + D + D^3 + D^4;$$

$$g_2(D) = 1 + D + D^2 + D^3 + D^4.$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-4)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; (bit $u(K-1)$ is placed in the register D1, and bit $u(K-4)$ is placed in the register D4). The coded bits are then defined by the following set of linear equations:

For $k = 0, \dots, K-1$;

$$c(3k) = u(k) \oplus u(k-2) \oplus u(k-4), \text{ where } \oplus \text{ denotes modulo-2 addition;}$$

$$c(3k + 1) = u(k) \oplus u(k-1) \oplus u(k-3) \oplus u(k-4);$$

$$c(3k + 2) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-3) \oplus u(k-4).$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(3K-1)\}$.

4.4.8 Rate 1/4 Constraint length 9 Convolutional Encoder

This code is defined by the following generator polynomials:

$$g_0(D) = 1 + D^3 + D^4 + D^5 + D^7 + D^8;$$

$$g_1(D) = 1 + D^2 + D^5 + D^7 + D^8;$$

$$g_2(D) = 1 + D + D^3 + D^4 + D^5 + D^8;$$

$$g_3(D) = 1 + D + D^2 + D^3 + D^4 + D^6 + D^8.$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-8)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; (bit $u(K-1)$ is placed in the register D1, and bit $u(K-8)$ is placed in the register D8). The coded bits are then defined by the following set of linear equations:

For $k = 0, \dots, K-1$;

$$c(4k) = u(k) \oplus u(k-3) \oplus u(k-4) \oplus u(k-5) \oplus u(k-7) \oplus u(k-8), \text{ where } \oplus \text{ denotes modulo-2 addition;}$$

$$c(4k+1) = u(k) \oplus u(k-2) \oplus u(k-5) \oplus u(k-7) \oplus u(k-8);$$

$$c(4k+2) = u(k) \oplus u(k-1) \oplus u(k-3) \oplus u(k-4) \oplus u(k-5) \oplus u(k-8);$$

$$c(4k+3) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-3) \oplus u(k-4) \oplus u(k-6) \oplus u(k-8).$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(4K-1)\}$.

4.4.9 Rate 1/3 Constraint length 9 Convolutional Encoder

This code is defined by the following generator polynomials:

$$g_0(D) = 1 + D^2 + D^3 + D^5 + D^6 + D^7 + D^8;$$

$$g_1(D) = 1 + D + D^3 + D^4 + D^7 + D^8;$$

$$g_2(D) = 1 + D + D^2 + D^5 + D^8.$$

The encoder is initialized with bits $\{u(K-1), u(K-2), \dots, u(K-8)\}$ from the input data block $\{u(0), u(1), \dots, u(K-1)\}$ to be encoded; (bit $u(K-1)$ is placed in the register D1, and bit $u(K-8)$ is placed in the register D8). The coded bits are then defined by the following set of linear equations:

For $k = 0, \dots, K-1$;

$$c(3k) = u(k) \oplus u(k-2) \oplus u(k-3) \oplus u(k-5) \oplus u(k-6) \oplus u(k-7) \oplus u(k-8), \text{ where } \oplus \text{ denotes modulo-2 addition;}$$

$$c(3k+1) = u(k) \oplus u(k-1) \oplus u(k-3) \oplus u(k-4) \oplus u(k-7) \oplus u(k-8);$$

$$c(3k+2) = u(k) \oplus u(k-1) \oplus u(k-2) \oplus u(k-5) \oplus u(k-8).$$

This results in a block of coded bits $\{c(0), c(1), \dots, c(3K-1)\}$.

4.5 Puncturing and repetition

The number of available free bits on a burst may not equal the number of coded bits output by the convolutional encoder. In this case, selected coded bits are either punctured (not processed for transmission) or repeated (transmitted twice) as needed to match the coded output to the available payload. The coded bits to be punctured and/or repeated are specified by channel-dependent puncturing and repetition masks. These masks take the form of an $n \times L$ integer array, in which the i^{th} row applies to the coded bits produced by the $g_i(D)$ generator polynomial, $i = 0, \dots, n-1$, and each entry specifies the number of times that the corresponding coded bit is to be transmitted. The parameter L denotes the period of the pattern. If the period is less than the total number of encoder input (information plus tail bits), the mask is reapplied on a periodic basis. If the number of encoder input is not divisible by L , the mask applies on all the encoder input and stops at the end of the encoder input. In some instances, prefix and suffix masks are applied at the beginning and end of the burst, respectively, to facilitate the rate matching.

The puncturing and repetition masks used in GMR-1 for the Rate 1/2, Rate 1/3, and Rate 1/5 convolutional code ($K = 5$) are listed in tables 4.3, 4.4 and 4.5 respectively. The puncturing masks used for Rate 1/2 convolutional code with constraint length $K = 7$ are listed in table 4.6. The puncturing masks used for Rate 1/2 convolutional code with constraint length $K = 9$ are listed in table 4.7. The puncturing masks used for Rate 1/4 convolutional code with constraint length $K = 6$ are listed in table 4.7a. The identifier $P(r;L)$ denotes the preferred puncturing mask used for circuit-switched services in which r coded bits are punctured every L input bits to the convolutional encoder. The time-reversed version of this mask is denoted by $P^*(r;L)$.

The puncturing/repetition masks used for convolutionally-encoded packet-switched services are formed as concatenations of the five basic masks denoted A, B, C, D, and E in table 4.3. This allows complex puncturing and repetition patterns to be specified by short mathematical descriptions. For example, the composite mask $P = A(BC)^{10}D$ denotes the puncture pattern in which mask A is applied at the beginning of the burst; the combination of mask B followed by mask C is applied 10 times during the middle of the burst; and, finally, mask D is applied at the end of the burst.

Same as clause 4.7.3 in GMR-1 05.003 [3].

4.8 Interleaving

Intraburst and interburst interleaving schemes are based on block interleaving methods with pseudorandom permutations and are channel dependent.

4.8.1 Intraburst interleaving

Intraburst interleaving is performed by mapping the block of the coded bits $\{c(0), c(1), \dots, c(M-1)\}$ into a $N \times 8$ matrix by rows, interchanging the columns using the pseudorandom permutation factor of 5, and reading out blocks of data by columns. Matrix dimension N is channel dependent and $N = \lceil M/8 \rceil$.

When columns are interchanged the index of the matrix element (i, j) changes to (i, j_p) , where $j_p = (j \times 5) \bmod 8$.

When the data is read out by columns, note there may be only $N-1$ elements in certain columns.

4.8.2 Interburst interleaving

Same as clause 4.8.2 in GMR-1 05.003 [3].

4.9 Scrambling

Same as clause 4.9 in GMR-1 05.003 [3].

4.10 LDPC Codes

4.10.1 General Operations

LDPC encoder systematically encodes an input block of size k_{ldpc} , $\mathbf{i} = (i_0, i_1, \dots, i_{k_{ldpc}-1})$ onto a codeword of size n_{ldpc} , $\mathbf{c} = (i_0, i_1, \dots, i_{k_{ldpc}-1}, p_0, p_1, \dots, p_{n_{ldpc}-k_{ldpc}-1})$. In order to match the exact burst structure shortening, repeating and/or puncturing can be applied. The number of shortened, repeated or punctured bits will be denoted by XS , XR and XP , respectively. Each procedure is described as follows.

Shortening

Set the first XS bits in the input block to 0 before encoding. Omit these bits from the resulting codeword before transmission. The transmission of the codeword starts in the given order from i_{XS} and ends with $p_{n_{ldpc}-k_{ldpc}-1}$.

Repeating

Repeat the transmission of the first XR transmitted bits, i.e. transmit:

$$i_{XS}, i_{XS}, i_{XS+1}, i_{XS+1}, \dots, i_{XS+XR-1}, i_{XS+XR-1}, i_{XS+XR}, i_{XS+XR+1}, \dots, p_{n_{ldpc}-k_{ldpc}-1}$$

Puncturing

For PNB2(5,3) rate 9/10, do not transmit the following XP systematic bits:

$$i_{k_{ldpc}-4XP+3}, i_{k_{ldpc}-4(XP-1)+3}, i_{k_{ldpc}-4(XP-2)+3}, \dots, i_{k_{ldpc}-1}$$

For PNB2(5,12) rate 9/10, do not transmit the following XP systematic bits:

$$i_{k_{ldpc}-4XP}, i_{k_{ldpc}-4(XP-1)}, i_{k_{ldpc}-4(XP-2)}, \dots, i_{k_{ldpc}-4}$$

For all other code rates, do not transmit the following XP parity bits: $p_0, p_4, p_8, \dots, p_{4(XP-1)}$

As a result, the effective rate of the LDPC code is $R_{eff} = \frac{k_{ldpc} - XS}{n_{ldpc} - XS + XR - XP}$. The block sizes and modulation

types of the LDPC codes for PNB2(5,12) and PNB2(5,3) described in the present document are shown in tables 4.8 and 4.10, respectively.

Table 4.8: PNB2(5,12) LDPC Code Block Sizes

Code	Modulation	k_{ldpc}	n_{ldpc}	XS	XR	XP (notes 1 and 2)	R_{eff} (with $XP=0$)
2/3 C1	QPSK	2960	4440	0	0	0 or 96	2/3
2/3 C2	16APSK	5920	8880	0	0	0 or 192	2/3
3/4	32APSK	8352	11136	40	4	0 or 240	0,7488
4/5 C1	QPSK	3552	4440	0	0	0 or 96	4/5
4/5 C2	16APSK	7104	8880	0	0	0 or 192	4/5
4/5 C3	32APSK	8880	11100	0	0	0 or 240	4/5
9/10 C1	QPSK	4032	4480	40	0	0 or 96	0,899
9/10 C2	16APSK	7992	8880	0	0	0 or 192	9/10
1/2	QPSK	2232	4464	24	0	0 or 96	0,497

NOTE 1: $XP = 0$ means no puncturing.
NOTE 2: $XP = 0$ is for all code rates and modulation types of uplink PNB2(5,12).

4.10.2 LDPC Encoding

The task of the encoder is to determine $n_{ldpc} - k_{ldpc}$ parity bits $(p_0, p_1, \dots, p_{n_{ldpc}-k_{ldpc}-1})$ for every block of k_{ldpc} input bits, $(i_0, i_1, \dots, i_{k_{ldpc}-1})$. The procedure is follows:

- Initialize $p_0 = p_1 = p_2 = \dots = p_{n_{ldpc}-k_{ldpc}-1} = 0$.
- Accumulate the first input bit, i_0 , at parity bit addresses specified in the first row of tables A.1 to A.9, and tables A.10 to A.18. For example, for code 2/3 C1 (table A.1):

$$p_{1025} = p_{1025} \oplus i_0$$

$$p_{1277} = p_{1277} \oplus i_0$$

$$p_{1247} = p_{1247} \oplus i_0$$

$$p_{1429} = p_{1429} \oplus i_0$$

$$p_{838} = p_{838} \oplus i_0$$

$$p_{836} = p_{836} \oplus i_0$$

$$p_{93} = p_{93} \oplus i_0$$

$$p_{104} = p_{104} \oplus i_0$$

(All additions are modulo 2).

- For the next $M-1$ input bits, $i_m, m = 1, 2, \dots, M-1$ accumulate i_m at parity bit addresses $\{x + m \bmod M \times q\} \bmod (n_{ldpc} - k_{ldpc})$ where x denotes the address of the parity bit accumulator corresponding to the first bit i_0 , and M and q are code dependent constants specified in tables 4.9 and 4.11. Continuing with the example, $M = 74, q = 20$ for code 2/3 C1. So for example for input bit i_1 , the following operations are performed:

$$p_{1045} = p_{1045} \oplus i_1$$

$$p_{1297} = p_{1297} \oplus i_1$$

$$p_{1267} = p_{1267} \oplus i_1$$

$$p_{1449} = p_{1449} \oplus i_1$$

$$p_{858} = p_{858} \oplus i_1$$

$$p_{856} = p_{856} \oplus i_1$$

$$p_{113} = p_{113} \oplus i_1$$

$$p_{124} = p_{124} \oplus i_1$$

For the $(M + 1)^{\text{st}}$ input bit i_M , the addresses of the parity bit accumulators are given in the second row of the tables A.1 to A.9, and tables A.10 to A.18. In a similar manner the addresses of the parity bit accumulators for the following $M-1$ input bits $i_m, m = M + 1, M + 2, \dots, 2M - 1$ are obtained using the formula $\{x + m \bmod M \times q\} \bmod (n_{ldpc} - k_{ldpc})$ where x denotes the address of the parity bit accumulator corresponding to the input bit i_M , i.e. the entries in the second row of the tables A.1 to A.9, and tables A.10 to A.18.

- In a similar manner, for every group of M new input bits, a new row from tables A.1 to A.9, and tables A.10 to A.18 are used to find the addresses of the parity bit accumulators.

After all of the input bits are exhausted, the final parity bits are obtained as follows:

- sequentially perform the following operations starting with $i = 1$;
- $p_i = p_i \oplus p_{i-1}, \quad i = 1, 2, \dots, n_{ldpc} - k_{ldpc} - 1$;
- final content of $p_i, \quad i = 0, 1, \dots, n_{ldpc} - k_{ldpc} - 1$ is equal to the parity bit p_i .

4.10.3 Bit Interleaver

For 16-APSK, and 32-APSK modulation formats, the output of the LDPC encoder is bit interleaved using a block interleaver. Data is serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB2(5,12) codes, the block interleaver has 2220 rows when $XP = 0$ and 2172 rows when $XP \neq 0$. For PNB2(5,3) codes, the block interleaver has 479 rows. For all the codes, the block interleaver has 4 columns for 16-APSK modulation and 5 columns for 32-APSK modulation.

- For code 2/3 C2, bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the interleaver output determine the i^{th} 16APSK symbol.
- For code 4/5 C2, bits $4i + 2$, $4i + 3$, $4i$ and $4i + 1$ of the interleaver output determine the i^{th} 16APSK symbol.
- For code 9/10 C2, bits $4i$, $4i + 2$, $4i + 1$ and $4i + 3$ of the interleaver output determine the i^{th} 16APSK symbol.
- For codes 3/4 and 4/5 C3, bits $5i + 4$, $5i + 2$, $5i + 3$, $5i + 1$ and $5i$ of the interleaver output determine the i^{th} 32APSK symbol.
- For $\pi/4$ QPSK modulation, there is no interleaving. Bits $2i$ and $2i + 1$ of the LDPC encoder determines the i^{th} $\pi/4$ QPSK symbol.

4.11 Turbo codes

4.11.1 Turbo encoder

The Turbo encoder consists of a Parallel Concatenated Convolutional Code (PCCC) with two constituent encoders. Each of the encoders consists of 8 states and has the same transfer function. The transfer function of the 8-state constituent code for PCCC is:

$$G(D) = \begin{bmatrix} 1 & \frac{n_0(D)}{d(D)} & \frac{n_1(D)}{d(D)} \end{bmatrix}$$

where $d(D) = 1 + D^2 + D^3$, $n_0(D) = 1 + D + D^3$, and $n_1(D) = 1 + D + D^2 + D^3$.

The structure of Turbo encoder with an overall code rate of 1/5 is illustrated in figure 4.1.

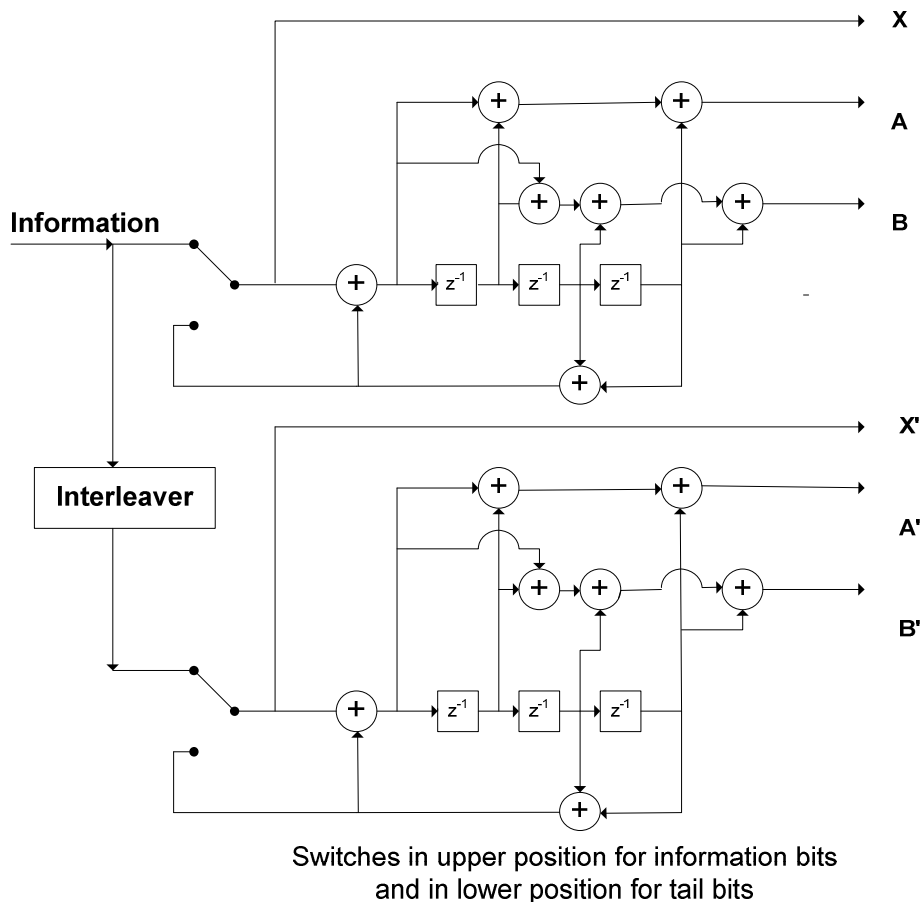

Figure 4.1 Structure of Turbo encoder

Input information that is fed to the first encoder is interleaved by the Turbo code internal interleaver before being fed into the second encoder. Each of the shift registers of the 8-state constituent encoders are initialized to zero before the encoding of the input bits. The constituent encoders are clocked with the switches in the UP position.

If input to the Turbo encoder is x_1, x_2, \dots, x_K then the encoded output is given by:

$$x_1, A_1, B_1, A_1', B_1' \ x_2, A_2, B_2, A_2', B_2' \dots \dots \dots \ x_K, A_K, B_K, A_K', B_K'$$

The bits output from Turbo code internal interleaver are denoted by x'_1, x'_2, \dots, x'_K , and these bits are to be input to the second 8-state constituent encoder.

The encoded outputs are punctured according to the defined puncturing matrices. Each puncturing matrix would have 5 rows corresponding to outputs X, A, B, A' and B'. This is defined in clause 4.11.4.

4.11.2 Turbo Code Termination

The turbo encoder shall generate 6/R tail output symbols following the encoded data output symbols. This tail output symbol sequence shall be identical to the one generated by the encoder shown in figure 4.1. The tail output symbols are generated after the constituent encoders have been clocked K times with the switches in the UP position. The first 3/R tail output symbols are generated by clocking Constituent Encoder 1 three times with its switch in the down position while Constituent Encoder 2 is not clocked and puncturing and repeating the resulting constituent encoder output symbols. The last 3/R tail output symbols are generated by clocking Constituent Encoder 2 three times with its switch in the down position while Constituent Encoder 1 is not clocked and puncturing and repeating the resulting constituent encoder output symbols.

The constituent encoder output symbol puncturing and symbol repetition shall be as specified in table 4.29a. Within a puncturing pattern, a "0" means that the symbol shall be deleted and a "1" means that a symbol shall be passed. For rate 1/2 turbo codes, the tail output symbols for each of the first three tail bit periods shall be XA, and the tail output symbols for each of the last three tail bit periods shall be X'A'. For rate 1/3 turbo codes, the tail output symbols for each of the first three tail bit periods shall be XXA, and the tail output symbols for each of the last three tail bit periods shall be X'X'A'. For rate 1/4 turbo codes, the tail output symbols for each of the first three tail bit periods shall be XXAB, and the tail output symbols for each of the last three tail bit periods shall be X'X'A'B'. For rate 1/5 turbo codes, the tail output symbols for each of the first three tail bit periods shall be XXXAB, and the tail output symbols for each of the last three tail bit periods shall be X' X' X' A' B'.

Table 4.29a: Puncturing and symbol repetition patterns for Tail bit periods

Output	Rate=1/2	Rate=1/3	Rate=1/4	Rate=1/5
X	111 000	222 000	222 000	333 000
A	111 000	111 000	111 000	111 000
B	000 000	000 000	111 000	111 000
X'	000 111	000 222	000 222	000 333
A'	000 111	000 111	000 111	000 111
B'	000 000	000 000	000 111	000 111

4.11.3 Turbo code internal interleaver

The turbo interleaver, which is part of the turbo encoder, shall block interleave the data, frame quality indicator (CRC), and reserved bits input to the turbo encoder.

The turbo interleaver shall be functionally equivalent to an approach where the entire sequence of turbo interleaver input bits are written sequentially into an array at a sequence of addresses, and then the entire sequence is read out from a sequence of addresses that are defined by the procedure described below.

Let the sequence of input addresses be from 0 to $K - 1$, where K is the number of symbols in the turbo interleaver. Then, the sequence of interleaver output addresses shall be equivalent to those generated by the procedure described below.

- 1) Determine the turbo interleaver parameter, n , where n is the smallest integer such that $K \leq 2^n + 5$. Table 4.29b gives this parameter.
- 2) Initialize an $(n + 5)$ -bit counter to 0.
- 3) Extract the n most significant bits (msbs) from the counter and add one to form a new value. Then, discard all except the n least significant bits (lsbs) of this value.
- 4) Obtain the n -bit output of the table lookup defined in table 4.29c with a read address equal to the five lsbs of the counter. Note that this table depends on the value of n .
- 5) Multiply the values obtained in Steps 3 and 4, and discard all except the n lsbs.
- 6) Bit-reverse the five lsbs of the counter.
- 7) Form a tentative output address that has its msbs equal to the value obtained in Step 6 and its lsbs equal to the value obtained in Step 5.
- 8) Accept the tentative output address as an output address if it is less than K otherwise, discard it.
- 9) Increment the counter and repeat Steps 3 through 8 until all K interleaver output addresses are obtained.

- For Rate 3/4 PNB3(5,12) QPSK, the n = 7 column in table 4.7 c is replaced by:
 - 113, 127, 89, 101, 31, 3, 61, 47, 37, 83, 119, 7, 57, 123, 97, 73, 85, 43, 55, 23, 9, 41, 93, 87, 63, 11, 79, 19, 81, 53, 29, 69.

- For Rate 2/3 PNB3(5,12) 16APSK carrying ULMAP the $n = 7$ column in table 4.7c is replaced by:
 - 15, 127, 89, 1, 31, 3, 61, 47, 37, 17, 119, 7, 57, 123, 95, 5, 85, 43, 55, 23, 9, 41, 93, 87, 63, 11, 13, 19, 81, 53, 29, 69.
- For Rate 2/3 PNB3(10,3) 16APSK carrying ULMAP the $n = 7$ column in table 4.7c is replaced by:
 - 101, 17, 11, 31, 19, 53, 113, 127, 17, 23, 67, 57, 73, 95, 5, 67, 107, 55, 89, 15, 41, 73, 37, 63, 15, 13, 15, 81, 97, 41, 53, 37.
- For Rate 3/4 PNB3(10,3) QPSK carrying ULMAP, the $n = 6$ column in table 4.7c is replaced by:
 - 41, 27, 3, 13, 29, 5, 1, 31, 23, 9, 51, 31, 17, 5, 39, 1, 19, 29, 61, 13, 45, 5, 33, 15, 43, 9, 15, 37, 17, 5, 15, 33.

4.11.4 Turbo Code Puncturing

After turbo code encoding, the systematic bits are transmitted without any puncturing. Parity bits of the first and second encoders undergo a stage of puncturing at first. Table 4.29d specifies the first puncturing stage.

Here each row of the puncturing matrix corresponds to outputs X, A, B, A', B'.

Table 4.29d: Puncturing Tables for the First Puncturing Stage

Identifier	Puncturing Table	Code rate
P(6;2)	1 1 1 0 0 0 0 1 0 0	Puncturing mask that if repeatedly applied results in a code rate of 1/2.
P(34;10)	1 1 1 1 1 1 1 1 1 1 1 0 0 0 1 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 1 0 0 1 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 5/8.
P(22;6)	1 1 1 1 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 3/4.
P(38;10)	1 1 1 1 1 1 1 1 1 1 1 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 5/6.
P(14;4)	1 1 1 1 1 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 2/3.
P(10;3)	1 1 1 1 0 0 0 0 0 0 1 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 3/5.
P(50;14)	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 0 0 0 1 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 1 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 7/10.

Identifier	Puncturing Table	Code rate
P(30;8)	1 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 4/5.
P(54;16)	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 0 1 0 0 1 0 0 0 1 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 1 0 0 1 0 0 0 1 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 8/13.
P(58;16)	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0 1 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0 0 1 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	Puncturing mask that if repeatedly applied results in a code rate of 8/11.

After the first stage puncturing, the turbo encoded data might go through a second stage of puncturing OR a second stage of depuncturing so that the coded block sizes are equal to the payload size for the particular burst.

The second stage puncturing table is given in tables 4.29e, 4.29f and 4.29g. Here the y^{th} survived parity bit of the first encoder and the y^{th} survived parity bit of the second encoder are punctured. The values for y are as given in the table.

Table 4.29e: Punctured Positions for the Second Stage Puncturing

Identifier	PNB3(5,3)	PNB3(5,12)	PNB3(10,3)	PNB3(10,3) carrying ULMAP
P1	34x, x = 1, 2, ..., 7	111x, x = 1, 2, ..., 10		
P2	24x, x = 1, 2, ..., 7	63x, x = 1, 2, ..., 13		
P3	17x, x = 1, 2, 7	138x, x = 1, 2, 3, 4		
P4	11x, x = 1, 2, ..., 7	20x, x = 1, 2, ..., 18		
P5	40x, x = 1, 2, 8	123x, x = 1, 2, ..., 6	6x, x = 1..112	4,7, (1 + 9x), x = 0, ..71

Table 4.29f: Punctured Positions for the Second Stage Puncturing

Identifier	PNB3(5,3), carrying ULMAP	PNB3(10,3)- carrying ULMAP
P6	9x, x = 1, 2, ..., 18	8 and (15x + 1), x = 0, ..25
P7		7x, x = 1, ..25

Table 4.29g: Punctured positions for Second stage puncturing

Identifier	PNB3(2,6)- Uplink	PNB3(2,6)- Downlink
P8	20x, x = 1, 2, ..., 6	
P9	13x, x = 1, 2, ..., 6	
P10		72x, x = 1
P11		52x, x = 1, 2
P12		32x, x = 1

For example for PNB3(5,3) Rate 1/2 burst, there are 480 information bits and encoding with the Rate 1/5 Turbo code results in 2 412 bits (including the 12 tail bits). In the first stage of puncturing, puncturing matrix P(6;2) is applied, after which 972 coded bits remain. None of the systematic bits are punctured. 240 bits corresponding to the first parity of the first encoder and 240 bits corresponding to the first parity of the second encoder are punctured. All the 480 bits corresponding to the second parity of the first encoder and all the 480 bits corresponding to the first parity of the second encoder are punctured. No tail bits are punctured. Thus, there are a total of 1 440 coded bits that are punctured from the first stage of puncturing.

In the second stage of puncturing (which corresponds to case P1 in table 4.29e) every 34th bit of the surviving 240 bits corresponding to the first parity of the first encoder is additionally punctured to result in an additional puncturing of 7 bits. Also, every 34th bit of the surviving 240 bits corresponding to the second parity of the second encoder is additionally punctured to result in an additional puncturing of 7 more bits. Thus there are a total of additional 14 coded bits that are punctured to result in a block of 958 coded bits.

The second stage of depuncturing is given in table 4.29h. Here the yth punctured parity bit of the first parity output of the first encoder (from first stage of puncturing) and the yth punctured parity bit of the first parity output of the second encoder (from first stage of puncturing) are de-punctured. The values for y are as given in table 4.29h.

Table 4.29h: Positions for Second stage Depuncturing

Code Rate	PNB 3(5, 3) carrying ULMAP	PNB3 (5,12) carrying ULMAP-	PNB3 (10, 3)	PNB3 (10,3) carrying ULMAP
D1	102x, x = 1	72x, x = 1, 2, ..., 14	65x, x = 1, ...8	25x, x = 1, ..16
D2		298x, x = 1, 2, ..., 6	182x, x = 1, ..5	
D3	32x, x = 1, 2, .. 15	212x, x = 1, 2, .. 12	435x, x = 1...3	100x, x = 1, ...8
D4	120x, x = 1, 2, .. 5	767x, x = 1, 2, ..., 4	259x, x = 1, ..6	
D5	40x, x = 1, 2, ... 20	1026x, x = 1, 2		

For example for PNB3(5,3) Rate 1/2 burst carrying ULMAP, there are 408 information bits and encoding with the Rate 1/5 Turbo code result in 2 052 bits (including the 12 tail bits). After puncturing matrix P(6;2) is applied 828 coded bits remain. None of the systematic bits are punctured. 204 bits corresponding to the first parity of the first encoder and 204 bits corresponding to the first parity of the second encoder are punctured. All the 408 bits corresponding to the second parity output of the first encoder and all the 408 coded bits corresponding to the second parity output of the second encoder are punctured. None of the tail bits are punctured. Thus, a total of 1 224 coded bits are punctured after the first stage of puncturing. In the second stage of depuncturing (which corresponds to case D1 in table 4.29h), the focus is on the first parity of the first encoder and the first parity of the second encoder. Of the 204 punctured bits corresponding to the first parity of the first encoder, the 102nd bit is depunctured. Similarly, of the 204 punctured bits corresponding to the first parity of the second encoder, the 102nd bit is depunctured. Thus, by the second-stage depuncturing process two bits that were punctured in the first stage of puncturing are depunctured. Thus, we have a total of 830 coded bits.

Same as clause 6.5.3 in GMR-1 05.003 [3].

6.5a Random Access Channel3 (RACH3)

The message delivered to the encoder consists of 68 information bits $\{d_1(0), \dots, d_1(67)\}$.

6.5a.1 Channel coding

A 8-bit CRC is applied to the 68 message bits as specified in clause 4.3. An 8-bit masking function is applied to the block of 76 CRC-protected bits $\{u(0), \dots, u(75)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(75)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 67$ and $u'(i + 68) = u(i + 68) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 76 bits $\{u'(0), \dots, u'(75)\}$ is delivered to the encoder.

The resultant block of 76 CRC-protected bits $\{u'(0), \dots, u'(75)\}$ is then encoded via the Rate 1/4 convolutional code as specified in clause 4.4.8. Convolutional encoding produces a block of 304 coded bits $\{b(0), \dots, b(303)\}$. Puncturing is performed using puncturing mask P(6;5) as defined in table 4.7b. This process results in the puncturing of 90 bits with indices $20k, 20k + 5, 20k + 12, 20k + 13, 20k + 15$ and $20k + 17$ for $(k = 0, \dots, 14)$. Additionally the bits 100 and 200 are depunctured (the zeros in those positions are replaced by a one). Thus we obtain a code block of size 216 bits $\{c(0), \dots, c(215)\}$.

6.5a.2 Interleaving

Same as clause 4.8.1.

6.5a.3 Scrambling and multiplexing

Same as clause 4.9 in GMR-1 05.003 [3].

6.6 Cell Broadcast CHannel (CBCH)

Same as clause 6.13.2 in GMR-1 05.003 [3].

6.13.3 Scrambling and multiplexing

Same as clause 6.13.3 in GMR-1 05.003 [3].

6.13a GPS Broadcast Channel3 (GBCH3)

Same as clause 6.13 in GMR-1 05.003 [3].

6.13a.1 Channel coding

Same as clause 6.13.1 in GMR-1 05.003 [3] except that the resultant block of 208 CRC-protected bits $\{u(0), \dots, u(207)\}$ is then encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 624 coded bits $\{b(0), \dots, b(623)\}$. Puncturing is performed using mask P(12,13) as listed in table 4.7c. This action results in the puncturing of 192 bits to result in 432 coded bits $\{c(0), \dots, c(431)\}$.

6.13a.2 Interleaving

Same as clause 6.13.2 in GMR-1 05.003 [3].

6.13a.3 Scrambling and multiplexing

Same as clause 6.13.3 in GMR-1 05.003 [3].

6.14 ULMAP

PNB3(5,3), PNB3(5,12), and PNB3(10,3) downlink burst can carry ULMAP.

6.14.1 ULMAP for PNB3 (5,3)/downlink

ULMAP with 32 message bits is defined for PNB3(5,3).

6.14.1.1 Channel coding

The message bits $\{u(0), \dots, u(31)\}$ is encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 96 coded bits $\{b(0), \dots, b(95)\}$. A puncturing matrix P(4;4) as shown in table 4.7c is applied on this encoded block and this results in puncturing of 32 bits to result in a coded block of 64 bits $\{c(0), \dots, c(63)\}$.

6.14.1.2 Interleaving

The coded block $\{c(0), \dots, c(63)\}$ is interleaved as in clause 4.8.1.

6.14.1.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in block $\{c'(0), \dots, c'(63)\}$.

6.14.1.4 Repetition

This block then goes through codeword-wise repetition, which results in a coded block of 128 bits $\{c'(0), \dots, c'(127)\}$.

Therefore:

$$c''(i + k * 64) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 63\}$$

6.14.2 ULMAP for PNB3(5,12)/downlink

ULMAP with 80 message bits is defined for PNB3(5,12)/downlink.

6.14.2.1 Channel coding

The message bits $\{u(0), \dots, u(79)\}$ is encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 240 coded bits $\{b(0), \dots, b(239)\}$. A puncturing matrix P(4;4) as shown in table 4.7c is applied on this encoded block and this results in puncturing of 80 bits to result in a coded block of 160 bits $\{c(0), \dots, c(159)\}$.

6.14.2.2 Interleaving

The coded block $\{c(0), \dots, c(159)\}$ is interleaved as in clause 4.8.1.

6.14.2.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in block $\{c'(0), \dots, c'(159)\}$.

6.14.2.4 Repetition

The block $\{c'(0), \dots, c'(159)\}$ then goes through codeword-wise repetition, which results in a coded block of 320 bits $\{c'(0), \dots, c'(319)\}$.

Therefore:

$$c''(i + k * 160) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 159\}$$

6.14.3 ULMAP for PNB3 (10,3)

ULMAP with 64 message bits is defined for PNB3(10,3).

6.14.3.1 Channel coding

The message bits $\{u(0), \dots, u(63)\}$ is encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 192 coded bits $\{b(0), \dots, b(191)\}$. A puncturing matrix P(4;4) as shown in table 4.7c is applied on this encoded block and this results in puncturing of 64 bits to result in a coded block of 128 bits $\{c(0), \dots, c(127)\}$.

6.14.3.2 Interleaving

The coded block $\{c(0), \dots, c(127)\}$ is interleaved as in clause 4.8.1.

6.14.3.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in a block $\{c'(0), \dots, c'(127)\}$.

6.14.3.4 Repetition

This block then goes through codeword-wise repetition, which results in a coded block of 256 bits $\{c''(0), \dots, c''(255)\}$.

Therefore:

$$c''(i + k * 128) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 127\}$$

7 Logical channel multiplexing

7.1 SACCH multiplexing

Same as clause 7.1 in GMR-1 05.003 [3].

7.2 Status field

Same as clause 7.2 in GMR-1 05.003 [3].

7.2.1 Power control field

Same as clause 7.2.1 in GMR-1 05.003 [3].

7.2.1.1 DCH (Dedicated Channel) Power control field

A status field block has a fixed size of 12 bits.

Power control field coding

A block of 12 status field bits $\{u(0), u(1), \dots, u(11)\}$ is encoded via (24, 12) Golay code as specified in clause 4.6. Golay encoding produces a block of 24 coded bits $\{c(0), c(1), \dots, c(23)\}$.

Interleaving:

The block of 24 coded bits $\{c(0), c(1), \dots, c(23)\}$ is interleaved to produce a 24-bit block $\{c'(0), c'(1), \dots, c'(23)\}$, where $c'(j) = c(k)$, $j = 0, \dots, 23$ and index k corresponding to each j shown in table 7.1.

Table 7.1: Index pairs for interleaving of coded power control field bits

j	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23
k	6	0	18	12	13	19	1	7	20	14	8	2	15	21	3	9	4	22	10	16	5	11	17	23

The 12-bit mask $m = \{1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0\}$ is then applied to the block of the interleaved bits as follows:

$$c''(j) = c'(k) \quad \text{for } k = 0, \dots, 11;$$

$$c''(j) = c'(k + 12) + m(k) \quad \text{for } k = 0, \dots, 11, \quad \text{where } + \text{ denotes modulo-2 addition.}$$

Finally, the 24-bit block $\{c''(0), c''(1), \dots, c''(23)\}$ is divided into six 4-bit blocks as follows:

$$S_p(B', k) = c''(j), \quad \text{where } j = 0, \dots, 23, B' = \text{INT}(j/4) \text{ and } k = j \bmod 4.$$

These 4-bit blocks are transmitted over the six consecutive DCH burst (PNB3 and/or KAB3 bursts). The synchronization of these blocks are addressed in GMR-1 3G 45.010 [6].

7.2.2 Comfort noise field

A comfort noise block delivered by the user unit has a fixed size of 80 bits.

Comfort noise field coding

The coding of the 80 comfort noise field bits $\{d(0), \dots, d(79)\}$ is done as specified for the TCH3 in clause 5.1.1.

Interleaving

The block of 104 interleaved bits $\{e'(0), \dots, e'(103)\}$ is obtained as specified in clause 5.1.2.

The block of 104 interleaved comfort noise bits $e'(k)$ is then divided into the 26 groups of 4-bits each as follows:

$$s_n(B'', j) = e'(k) \quad \text{where } B'' = \text{INT}(k/4), j = k \bmod 4 \text{ and } k = 0, \dots, 103.$$

These 4-bit groups are transmitted over the 26 consecutive dual keep-alive burst (DKAB) and FACCH3 bursts.

When the comfort noise field is transmitted over the DCH, the identical coding applied to the voice channel shall be used to comfort noise field coding.

7.2.3 Link Quality Indicator field

Link Quality Indicator (LQI) is a 1 bit field, S_Q , that represents the CRC pass/fail status of the bursts received over the DCH. Forward Link Quality Indicator (FQI) represents the CRC status of the burst received by UT while Return Link Quality Indicator (RQI) represents the CRC status of the burst received at the GS.

7.3 Status field with NTN bursts

7.3.1 Status field with NT6 and NT9 bursts

Same as clause 7.3.1 in GMR-1 05.003 [3].

7.3.2 Status field with NT3 bursts

7.3.2.1 Status field with NT3 bursts for encoded speech

Same as clause 7.3.2.1 in GMR-1 05.003 [3].

7.3.2.2 Status field with NT3 bursts for FACCH

Same as clause 7.3.2.2 in GMR-1 05.003 [3].

7.3.3 Status field with Keep-Alive Bursts (KAB)

Same as clause 7.3.3 in GMR-1 05.003 [3].

7.4 Status field with DCH bursts

7.4.1 Status field with PNB3(1,3), PNB3(1,6), and PNB3(1,8)

The status fields for PNB3(1,3), PNB3(1,6) and PNB3(1,8) speech bursts (DTCH) consist of 7 bits. The LQI bit, S_q , along with two spare bits are appended to the 4 power control field bits to form the status field block, $\{S_p(B',0), \dots, S_p(B',3), S_q, S_d, S_d\}$, where S_d is a spare bit. The status fields for PNB3(1,3), PNB3(1,6) and PNB3(1,8) data bursts (DACCH) consist of 4 power control field bits, 1 LQI bit. These 5 bits form the status field block $\{S_p(B',0), \dots, S_p(B',3), S_q\}$.

7.4.2 Status field with KAB3(1,3),

The status field for KAB3(1,3) consists of 5 bits: the LQI bit, S_q and the 4 power control field bits. The LQI bit, S_q , is repeated 4 times and added to 4 power control bits to form the status field block (total 8 bit coded status field). The bits in the block are arranged according to the following: $\{e0,e1, \dots,e7\} = \{S_p(B',0), S_q, S_p(B',1), S_q, S_p(B',2), S_q, S_p(B',3), S_q\}$. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on $\{e0,e1, \dots,e7\}$.

7.4.3 Status field with KAB3(1,6)

The status field for KAB3(1,6) consists of 5 bits: the LQI bit, S_q and the 4 power control field bits. The LQI bit, S_q , is repeated 8 times and the 4 power control bits are repeated twice to form the status field block (total 16 bit coded status field). The bits in the block are arranged according to the following: $\{e0,e1, \dots,e15\} = \{S_p(B',0), S_q, S_p(B',1), S_q, S_p(B',2), S_q, S_p(B',3), S_q, S_p(B',0), S_q, S_p(B',1), S_q, S_p(B',2), S_q, S_p(B',3), S_q\}$. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on $\{e0,e1, \dots,e15\}$.

7.4.4 Status field with KAB3(1,8)

The status field for KAB3(1,8) consists of 5 bits: the LQI bit, S_q and the 4 power control field bits. The LQI bit, S_q , is repeated 8 times and the 4 power control bits are repeated twice to form the status field block (total 16 bit coded status field). The bits in the block are arranged according to the following: $\{e0,e1, \dots,e15\} = \{S_p(B',0), S_q, S_p(B',1), S_q, S_p(B',2), S_q, S_p(B',3), S_q, S_p(B',0), S_q, S_p(B',1), S_q, S_p(B',2), S_q, S_p(B',3), S_q\}$. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on $\{e0,e1, \dots,e15\}$.

8 Encryption

Same as clause 8 in GMR-1 05.003 [3].

9 Packet Switched Channels

9.1 Packet Data Traffic Channels

Several types of bursts are used by the various logical channels in the downlink and uplink Packet Data Channels (PDCHs). The Packet Normal Bursts, PNB(m,n), are characterized by their transmission rate in multiples, m, of the basic transmission rate of 23,4 ksps, and their duration in multiples, n, of the timeslot of 40/24 ms. For example, PNB(4,3) is a burst transmitted at m = 4 times the basic rate (93,6 ksps transmission rate occupying a nominal bandwidth of 125 kHz) with a nominal duration n = 3 timeslots, or 5 ms.

Bursts transmitted over the downlink and uplink PDCHs consist of two parts:

- Public Information (PUI);
- PRivate Information (PRI).

PRI is also termed payload. The PRI comprises N message bits d_0 to d_{N-1} , as defined in clause 10.1 in GMR-1 3G 44.060 [5]. PUI is also called burst header, or physical layer header (hereafter referred to as PUI). The coding for the PUI and the various burst formats are described in the following clauses.

9.1.1 Public Information (PUI)

For all packet data bursts, the PUI comprises 12 information bits b_0 to b_{11} , as defined in GMR-1 3G 44.060 [5]. These 12 bits are encoded via the extended Golay (24,12) code as described in clause 4.6, where $u(i) = b_i$, $i = 0, \dots, 11$. The output from the Golay encoder is a block of 24 bits, $\{c(0), c(1), \dots, c(23)\}$. After Golay encoding, each encoded bit is repeated once to form the 48-bit coded PUI as $\{c(0), c(1), \dots, c(23), c(0), c(1), \dots, c(23)\}$. Note there are no interleaving, scrambling and encryption on PUI data.

9.1.1a Extended PUI (A/Gb mode only)

This clause only applies in A/Gb mode.

Forward link PNB2(5,12) -20 ms bursts contain an extended PUI. The 22 information bits of the extended PUI and the 12 bits of the PUI are encoded together using an 8-bit CRC, which is described in GMR-1 05.003 [3]. These 8 CRC bits and the 22 extended PUI bits form a block of length 30 bits, b_0 to b_{29} . These 30 bits are encoded using a rate 1/4 tail biting convolutional code, described in clause 4.4.4, that is then punctured to rate 5/16 (the puncturing pattern is given in table 4.8). The output is a block of 96 bits $\{c(0), c(1), \dots, c(95)\}$.

9.1.1b Public Information (PUI3)

PNB3(5,3), PNB3(5,12), and PNB3(10,3) downlink burst carry PUI3.

9.1.1b.1 PUI3 for PNB3(5,3)/downlink and PNB3 (5,12)/downlink

PUI3 for PNB3(5,3) and PNB3 (5,12) in the downlink contain 20 message bits. The USF field in the PUI3 is indicative of the presence of ULMAP in the burst.

9.1.1b.1.1 Channel coding

If the ULMAP is present in the burst then the information bits in PUI3 and ULMAP are encoded with the CRC polynomial. For bursts which do not contain ULMAP, the CRC polynomial is applied to only the 20 information bits in the PUI. A 3-bit CRC as specified in clause 4.3 is used. The resultant block of 23 CRC-protected bits $\{u(0), \dots, u(22)\}$ is then encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 69 coded bits $\{b(0), \dots, b(68)\}$. A puncturing matrix P(3;3) as shown in table 4.7c is applied. This process results in the puncturing of 21 bits with indices $9k$, $9k + 4$ and $9k + 8$ for $k = 0, 1, 2, 3..6$. Additionally bits 19, 42, 63 and 67 are also punctured to result in a coded block of size 44 bits given by $\{c(0), \dots, c(43)\}$.

9.1.1b.1.2 Interleaving

The coded block $\{c(0), \dots, c(43)\}$ is interleaved as in clause 4.8.1.

9.1.1b.1.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in a coded block $\{c'(0), \dots, c'(43)\}$.

9.1.1b.1.4 Repetition

After codeword-wise repetition the coded block of 44 bits result in a coded block of size 88 bits $\{c''(0), \dots, c''(87)\}$.

Therefore:

$$c''(i + k * 44) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 43\}$$

9.1.1b.2 PUI3 for PNB3(10,3)

PUI3 for PNB3(10,3) contains 27 message bits. The USF field in the PUI3 is indicative of the presence of ULMAP in the burst.

9.1.1b.2.1 Channel coding

If the ULMAP is present in the burst then the information bits in PUI3 and ULMAP are encoded with the CRC polynomial. For bursts which do not contain ULMAP, the CRC polynomial is applied to only the 27 information bits in the PUI.A 3-bit CRC polynomial as specified in clause 4.3 is used. The resultant block of 30 CRC-protected bits $\{u(0), \dots, u(29)\}$ is then encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 90 coded bits $\{b(0), \dots, b(89)\}$. Puncturing is performed by applying puncturing mask P(6,5) as specified in table 4.7c. This process results in the puncturing of 36 bits with indices $15k + 1$, $15k + 3$, $15k + 7$, $15k + 8$, $15k + 9$ and $15k + 14$ for $k = 0, 1, 2, 3..6$ to result in a coded block of size 54 bits given by $\{c(0), \dots, c(53)\}$.

9.1.1b.2.2 Interleaving

The coded block $\{c(0), \dots, c(53)\}$ is interleaved as in clause 4.8.1.

9.1.1b.2.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in coded block $\{c'(0), \dots, c'(53)\}$.

9.1.1b.2.4 Repetition

After codeword-wise repetition the coded block of 54 bits result in a coded block of size 108 bits $\{c''(0), \dots, c''(107)\}$.

Therefore:

$$c''(i + k * 54) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 53\}$$

9.1.1b.3 PUI3 for PNB3(2,6)

PUI3 for PNB3(2,6) in the downlink contains 18 message bits.

9.1.1b.3.1 Channel coding

The CRC polynomial is applied to the 18 information bits in the PUI.A 3-bit CRC polynomial as specified in clause 4.3 is used. The resultant block of 21 CRC-protected bits $\{u(0), \dots, u(20)\}$ is then encoded via the Rate 1/3 convolutional code as specified in clause 4.4.9. Convolutional encoding produces a block of 63 coded bits $\{b(0), \dots, b(62)\}$. Puncturing is performed by applying puncturing mask P(3;3) as specified in table 4.7c. This process results in the puncturing of 21 bits with indices $9k$, $9k + 4$ and $9k + 8$ for $k = 0, 1, 2, 3..6$. Additionally bits 29 and 60 are also punctured to result in a coded block of size 40 bits given by $\{c(0), \dots, c(39)\}$.

9.1.1b.3.2 Interleaving

The coded block $\{c(0), \dots, c(39)\}$ is interleaved as in clause 4.8.1.

9.1.1b.3.3 Scrambling and multiplexing

The interleaved coded block is scrambled and multiplexed as in clause 4.9 in GMR-1 05.003 [3] to result in a coded block $\{c'(0), \dots, c'(39)\}$.

9.1.1b.3.4 Repetition

After codeword wise repetition the coded block of 40 bits result in a coded block of size 80 bits $\{c''(0), \dots, c''(79)\}$.

Therefore:

$$c''(i + k * 40) = c'(i) \dots \text{for } k=0 \text{ and } k=1 \quad \{i = 0, 1, \dots, 39\}$$

9.1.2 Void

9.1.3 Packet Normal Burst PNB(4,3)

The information rate supported by the PNB(4,3) depends on the channel coding used. Channel coding rates of approximately 1/2, 5/8, and 3/4 are defined for the PNB(4,3). Independent of channel coding rate, the PNB(4,3) provides a common payload for 792 coded bits.

9.1.3.1 Rate 1/2 convolutional coding

A 16-bit CRC is applied to the 376 message bits d_0 to d_{375} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 375$. An 8-bit masking function is applied to the block of 392 CRC-protected bits $\{u(0), \dots, u(391)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(391)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 383$ and $u'(i + 384) = u(i + 384) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 392 bits $\{u'(0), \dots, u'(391)\}$ is delivered to the encoder.

The 392 bits $\{u'(0), \dots, u'(391)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 800 coded bits $\{b(0), \dots, b(799)\}$.

Puncturing is performed using the puncture mask P(1;48), as listed in table 4.6. After that, one bit in $\{b\}$ (with index 769) needs to be depunctured. This action turns out that 8 bits in $\{b\}$ with index $96k + 1$ ($k = 0, \dots, 7$) are punctured out. The result is a block of 792 coded bits $\{c(0), \dots, c(791)\}$.

9.1.3.2 Rate 5/8 convolutional coding

A 16-bit CRC is applied to the 472 message bits d_0 to d_{471} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 471$. An 8-bit masking function is applied to the block of 488 CRC-protected bits $\{u(0), \dots, u(487)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(487)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 479$ and $u'(i + 480) = u(i + 480) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 488 bits $\{u'(0), \dots, u'(487)\}$ is delivered to the encoder.

The 488 bits $\{u'(0), \dots, u'(487)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 992 coded bits $\{b(0), \dots, b(991)\}$.

Puncturing is performed using the puncture mask P(4;10) as listed in table 4.6. Besides, one more bit in $\{b\}$ (with index 991) needs to be punctured. This action turns out that 200 bits in $\{b\}$ with index $20k + 1$, $20k + 5$, $20k + 9$ ($k = 0, \dots, 49$), $20k + 17$ ($k = 0, \dots, 48$) and 991 are punctured out. The result is a block of 792 coded bits $\{c(0), \dots, c(791)\}$.

9.1.3.3 Rate 3/4 convolutional coding

A 16-bit CRC is applied to the 568 message bits d_0 to d_{567} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 567$. An 8-bit masking function is applied to the block of 584 CRC-protected bits $\{u(0), \dots, u(583)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(583)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 575$ and $u'(i + 576) = u(i + 576) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 584 bits $\{u'(0), \dots, u'(583)\}$ is delivered to the encoder.

The 584 bits $\{u'(0), \dots, u'(583)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 1 184 coded bits $\{b(0), \dots, b(1 183)\}$.

Puncturing is performed using the puncture mask P(2;3) as listed in table 4.6. After that, two bits in $\{b\}$ with index 1 179 and 1 180 are depunctured. This action turns out that 392 bits in $\{b\}$ with index $6k + 3$ and $6k + 4$ ($k = 0, \dots, 195$) are punctured out. The result is a block of 792 coded bits $\{c(0), \dots, c(791)\}$.

9.1.3.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.3.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.4 Packet Normal Burst PNB(5,3)

The information rate supported by the PNB(5,3) depends on the channel coding used. Channel coding rates of approximately 1/2, 5/8, and 3/4 are defined for the PNB(5,3). Independent of channel coding rate, the PNB(5,3) provides a common payload for 1 002 coded bits.

9.1.4.1 Rate 1/2 convolutional coding

A 16-bit CRC is applied to the 480 message bits d_0 to d_{479} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 479$. An 8-bit masking function is applied to the block of 496 CRC-protected bits $\{u(0), \dots, u(495)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(495)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 487$ and $u'(i + 488) = u(i + 488) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 496 bits $\{u'(0), \dots, u'(495)\}$ is delivered to the encoder.

The 496 bits $\{u'(0), \dots, u'(495)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 1 008 coded bits $\{b(0), \dots, b(1 007)\}$.

Puncturing is performed using the puncture mask P(1;84) as listed in table 4.6. This action turns out that 6 bits in $\{b\}$ with index $168k + 1$ ($k = 0, \dots, 5$) are punctured out. The result is a block of 1 002 coded bits $\{c(0), \dots, c(1 001)\}$.

9.1.4.2 Rate 5/8 convolutional coding

A 16-bit CRC is applied to the 608 message bits d_0 to d_{607} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 607$. An 8-bit masking function is applied to the block of 624 CRC-protected bits $\{u(0), \dots, u(623)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(623)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 615$ and $u'(i + 616) = u(i + 616) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 624 bits $\{u'(0), \dots, u'(623)\}$ is delivered to the encoder.

The 624 bits $\{u'(0), \dots, u'(623)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 1 264 coded bits $\{b(0), \dots, b(1 263)\}$.

Puncturing is performed using the puncture mask P(5;12) as listed in table 4.6. After that, one bit in $\{b\}$ with index 1 263 needs to be depunctured. This action turns out that 262 bits in $\{b\}$ with index $24k + 3$, $24k + 7$ ($k = 0, \dots, 52$) and $24k + 15$, $24k + 19$, $24k + 23$ ($k = 0, \dots, 51$) are punctured out. The result is a block of 1 002 coded bits $\{c(0), \dots, c(1 001)\}$.

9.1.4.3 Rate 3/4 convolutional coding

A 16-bit CRC is applied to the 728 message bits d_0 to d_{727} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 727$. An 8-bit masking function is applied to the block of 744 CRC-protected bits $\{u(0), \dots, u(743)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(743)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 735$ and $u'(i + 736) = u(i + 736) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 744 bits $\{u'(0), \dots, u'(743)\}$ is delivered to the encoder.

The 744 bits $\{u'(0), \dots, u'(743)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 1 504 coded bits $\{b(0), \dots, b(1\ 503)\}$.

Puncturing is performed using the puncture mask P(2;3) as listed in table 4.6. Besides, one more bit in $\{b\}$ with index 1 495 is punctured. This action turns out that 502 bits in $\{b\}$ with index $6k + 3$ ($k = 0, \dots, 250$), $6k + 4$ ($k = 0, \dots, 249$) and 1 495 are punctured out. The result is a block of 1 002 coded bits $\{c(0), \dots, c(1\ 001)\}$.

9.1.4.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.4.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.5 Void

9.1.6 Packet Normal Burst PNB(1,6)

The information rate supported by the PNB(1,6) depends on the channel coding used. Channel coding rates of approximately 6/10, 7/10, and 4/5 are defined for the PNB(1,6). Independent of channel coding rate, the PNB(1,6) provides a common payload for 366 coded bits.

9.1.6.1 Rate 3/5 convolutional coding

A 16-bit CRC is applied to the 192 message bits d_0 to d_{191} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 191$. An 8-bit masking function is applied to the block of 208 CRC-protected bits $\{u(0), \dots, u(207)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(207)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 199$ and $u'(i + 200) = u(i + 200) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 208 bits $\{u'(0), \dots, u'(207)\}$ is delivered to the encoder.

The 208 bits $\{u'(0), \dots, u'(207)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 432 coded bits $\{b(0), \dots, b(431)\}$.

Puncturing is performed using the puncture mask P(1;3), as listed in table 4.7. This action turns out that 72 bits in $\{b\}$ with index $6k + 1$ ($k = 0, \dots, 71$) are punctured out. After applying P(1;3), these bits will be depunctured: 37, 109, 181, 253, 325, 397. The result is a block of 366 coded bits $\{c(0), \dots, c(365)\}$.

9.1.6.2 Rate 7/10 convolutional coding

A 16-bit CRC is applied to the 232 message bits d_0 to d_{231} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 231$. An 8-bit masking function is applied to the block of 248 CRC-protected bits $\{u(0), \dots, u(247)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(247)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 239$ and $u'(i + 239) = u(i + 239) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 248 bits $\{u'(0), \dots, u'(247)\}$ is delivered to the encoder.

The 248 bits $\{u'(0), \dots, u'(247)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 512 coded bits $\{b(0), \dots, b(511)\}$.

Puncturing is performed using the puncture mask P(4;7) as listed in table 4.7. This action turns out that 146 bits in $\{b\}$ with index $14k$, $14k + 5$, ($k = 0, \dots, 36$) and $14k + 9$, $14k + 13$ ($k = 0, \dots, 35$) are punctured out. The result is a block of 366 coded bits $\{c(0), \dots, c(365)\}$.

9.1.6.3 Rate 4/5 convolutional coding

A 16-bit CRC is applied to the 272 message bits d_0 to d_{271} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 271$. An 8-bit masking function is applied to the block of 288 CRC-protected bits $\{u(0), \dots, u(287)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(287)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 279$ and $u'(i + 280) = u(i + 270) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 288 bits $\{u'(0), \dots, u'(287)\}$ is delivered to the encoder.

The 288 bits $\{u'(0), \dots, u'(287)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 592 coded bits $\{b(0), \dots, b(591)\}$.

Puncturing is performed using the puncture mask P(3;4) as listed in table 4.7. This action turns out that 222 bits in $\{b\}$ with index $8k + 3$, $8k + 4$, $8k + 7$ ($k = 0, \dots, 73$) are punctured out. After applying P(3;4), these bits also will be punctured: 0, 8, 576, 584. The result is a block of 366 coded bits $\{c(0), \dots, c(365)\}$.

9.1.6.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.6.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.7 Packet Normal Burst PNB(2,6)

The information rate supported by the PNB(2,6) depends on the channel coding used. Channel coding rates of approximately 3/5, 7/10, and 4/5 are defined for the PNB(2,6). Independent of channel coding rate, the PNB(2,6) provides a common payload for 810 coded bits.

9.1.7.1 Rate 3/5 convolutional coding

A 16-bit CRC is applied to the 456 message bits d_0 to d_{455} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 455$. An 8-bit masking function is applied to the block of 472 CRC-protected bits $\{u(0), \dots, u(471)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(471)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 463$ and $u'(i + 464) = u(i + 464) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 472 bits $\{u'(0), \dots, u'(471)\}$ is delivered to the encoder.

The 472 bits $\{u'(0), \dots, u'(471)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 960 coded bits $\{b(0), \dots, b(959)\}$.

Puncturing is performed using the puncture mask $P(1;3)$, as listed in table 4.7. This action turns out that 160 bits in $\{b\}$ with index $6k + 1$ ($k = 0, \dots, 159$) are punctured out. After applying $P(1;3)$ these bits will be depunctured: 73, 163, 253, 343, 433, 523, 613, 703, 793, 883. The result is a block of 810 coded bits $\{c(0), \dots, c(809)\}$.

9.1.7.2 Rate 7/10 convolutional coding

A 16-bit CRC is applied to the 544 message bits d_0 to d_{543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 543$. An 8-bit masking function is applied to the block of 560 CRC-protected bits $\{u(0), \dots, u(559)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(559)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 551$ and $u'(i + 552) = u(i + 552) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 560 bits $\{u'(0), \dots, u'(559)\}$ is delivered to the encoder.

The 560 bits $\{u'(0), \dots, u'(559)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 1 136 coded bits $\{b(0), \dots, b(1 135)\}$.

Puncturing is performed using the puncture mask $P(4;7)$ as listed in table 4.7. This action turns out that 325 bits in $\{b\}$ with index $14k$, ($k = 0, \dots, 81$) and $14k + 5$, $14k + 9$, $14k + 13$ ($k = 0, \dots, 80$). After applying $P(4;7)$, bit with index 2 will be punctured out. The result is a block of 810 coded bits $\{c(0), \dots, c(809)\}$.

9.1.7.3 Rate 4/5 convolutional coding

A 16-bit CRC is applied to the 624 message bits d_0 to d_{623} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 623$. An 8-bit masking function is applied to the block of 640 CRC-protected bits $\{u(0), \dots, u(639)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(639)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 631$ and $u'(i + 632) = u(i + 632) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 640 bits $\{u'(0), \dots, u'(639)\}$ is delivered to the encoder.

The 640 bits $\{u'(0), \dots, u'(639)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.1, where the constraint length $K = 9$ is used. Eight tail bits are added. The encoding results in a block of 1 296 coded bits $\{b(0), \dots, b(1 295)\}$.

Puncturing is performed using the puncture mask $P(3;4)$ as listed in table 4.7. This action turns out that 486 bits in $\{b\}$ with index $8k + 3$, $8k + 4$, $8k + 7$ ($k = 0, \dots, 161$) are punctured out. The result is a block of 810 coded bits $\{c(0), \dots, c(809)\}$.

9.1.7.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.7.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.8 Packet Normal Burst PNB2(5,12)

The information rate supported by the PNB2(5,12) depends on the modulation and the channel coding used. Modulations include 32APSK, 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates include 1/2, 2/3, 4/5, and 9/10. Punctured LDPC is used in the forward direction only.

9.1.8.1 $\pi/4$ QPSK Rate 0,497 LDPC Coding

A 8-bit CRC is applied to the 2200 message bits d_0 to d_{2199} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2199$. An 8-bit masking function is applied to the block of 2208 CRC-protected bits $\{u(0), \dots, u(2207)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2207)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2199$ and $u'(i + 2200) = u(i + 2200) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2208 bits $\{u'(0), \dots, u'(2207)\}$ is delivered to the encoder.

The 2208 bits $\{u'(0), \dots, u'(2207)\}$ are encoded via the rate 0,497 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$.

9.1.8.2 $\pi/4$ QPSK Rate 0,508 LDPC Coding

A 8-bit CRC is applied to the 2200 message bits d_0 to d_{2199} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2199$. An 8-bit masking function is applied to the block of 2208 CRC-protected bits $\{u(0), \dots, u(2207)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2207)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2199$ and $u'(i + 2200) = u(i + 2200) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2208 bits $\{u'(0), \dots, u'(2207)\}$ is delivered to the encoder.

The 2208 bits $\{u'(0), \dots, u'(2207)\}$ are encoded via the rate 0,508 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4344 coded bits $\{b(0), \dots, b(4343)\}$.

9.1.8.3 $\pi/4$ QPSK Rate 0,667 LDPC Coding

A 8-bit CRC is applied to the 2952 message bits d_0 to d_{2951} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2951$. An 8-bit masking function is applied to the block of 2960 CRC-protected bits $\{u(0), \dots, u(2959)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2959)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2951$ and $u'(i + 2952) = u(i + 2952) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2960 bits $\{u'(0), \dots, u'(2959)\}$ is delivered to the encoder.

The 2960 bits $\{u'(0), \dots, u'(2959)\}$ are encoded via the rate 0,667 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$.

9.1.8.4 $\pi/4$ QPSK Rate 0,681 LDPC Coding

A 8-bit CRC is applied to the 2952 message bits d_0 to d_{2951} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2951$. An 8-bit masking function is applied to the block of 2960 CRC-protected bits $\{u(0), \dots, u(2959)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2959)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2951$ and $u'(i + 2952) = u(i + 2952) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2960 bits $\{u'(0), \dots, u'(2959)\}$ is delivered to the encoder.

The 2960 bits $\{u'(0), \dots, u'(2959)\}$ are encoded via the rate 0,681 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4344 coded bits $\{b(0), \dots, b(4343)\}$.

9.1.8.5 $\pi/4$ QPSK Rate 0,800 LDPC Coding

A 8-bit CRC is applied to the 3544 message bits d_0 to d_{3543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3543$. An 8-bit masking function is applied to the block of 3552 CRC-protected bits $\{u(0), \dots, u(3551)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3552)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3543$ and $u'(i + 3544) = u(i + 3544) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3552 bits $\{u'(0), \dots, u'(3551)\}$ is delivered to the encoder.

The 3552 bits $\{u'(0), \dots, u'(3551)\}$ are encoded via the rate 0,800 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$.

9.1.8.6 $\pi/4$ QPSK Rate 0,818 LDPC Coding

A 8-bit CRC is applied to the 3544 message bits d_0 to d_{3543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3543$. An 8-bit masking function is applied to the block of 3552 CRC-protected bits $\{u(0), \dots, u(3551)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3552)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3543$ and $u'(i + 3544) = u(i + 3544) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3552 bits $\{u'(0), \dots, u'(3551)\}$ is delivered to the encoder.

The 3552 bits $\{u'(0), \dots, u'(3551)\}$ are encoded via the rate 0,818 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4344 coded bits $\{b(0), \dots, b(4343)\}$.

9.1.8.7 $\pi/4$ QPSK Rate 0,899 LDPC Coding

A 8-bit CRC is applied to the 3984 message bits d_0 to d_{3983} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3983$. An 8-bit masking function is applied to the block of 3992 CRC-protected bits $\{u(0), \dots, u(3991)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3991)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3983$ and $u'(i + 3984) = u(i + 3984) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3992 bits $\{u'(0), \dots, u'(3991)\}$ is delivered to the encoder.

The 3992 bits $\{u'(0), \dots, u'(3991)\}$ are encoded via the rate 0,899 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$.

9.1.8.8 $\pi/4$ QPSK Rate 0,919 LDPC Coding

A 8-bit CRC is applied to the 3984 message bits d_0 to d_{3983} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3983$. An 8-bit masking function is applied to the block of 3992 CRC-protected bits $\{u(0), \dots, u(3991)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3991)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3983$ and $u'(i + 3984) = u(i + 3984) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3992 bits $\{u'(0), \dots, u'(3991)\}$ is delivered to the encoder.

The 3992 bits $\{u'(0), \dots, u'(3991)\}$ are encoded via the rate 0,919 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 4344 coded bits $\{b(0), \dots, b(4343)\}$.

9.1.8.9 16APSK Rate 0,667 LDPC Coding

A 8-bit CRC is applied to the 5912 message bits d_0 to d_{5911} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 5911$. An 8-bit masking function is applied to the block of 5920 CRC-protected bits $\{u(0), \dots, u(5919)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(5919)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 5911$ and $u'(i + 5912) = u(i + 5912) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 5920 bits $\{u'(0), \dots, u'(5919)\}$ is delivered to the encoder.

The 5920 bits $\{u'(0), \dots, u'(5919)\}$ are encoded via the rate 0,667 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 8880 coded bits $\{b(0), \dots, b(8879)\}$.

9.1.8.10 16APSK Rate 0,681 LDPC Coding

A 8-bit CRC is applied to the 5912 message bits d_0 to d_{5911} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 5911$. An 8-bit masking function is applied to the block of 5920 CRC-protected bits $\{u(0), \dots, u(5919)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(5919)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 5911$ and $u'(i + 5912) = u(i + 5912) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 5920 bits $\{u'(0), \dots, u'(5919)\}$ is delivered to the encoder.

The 5920 bits $\{u'(0), \dots, u'(5919)\}$ are encoded via the rate 0,681 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 8688 coded bits $\{b(0), \dots, b(8687)\}$.

9.1.8.11 16APSK Rate 0,800 LDPC Coding

A 8-bit CRC is applied to the 7096 message bits d_0 to d_{7095} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 7095$. An 8-bit masking function is applied to the block of 7104 CRC-protected bits $\{u(0), \dots, u(7103)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(7103)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 7095$ and $u'(i + 7096) = u(i + 7096) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 7104 bits $\{u'(0), \dots, u'(7103)\}$ is delivered to the encoder.

The 7104 bits $\{u'(0), \dots, u'(7103)\}$ are encoded via the rate 0,800 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 8880 coded bits $\{b(0), \dots, b(8879)\}$.

9.1.8.12 16APSK Rate 0,818 LDPC Coding

A 8-bit CRC is applied to the 7096 message bits d_0 to d_{7095} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 7095$. An 8-bit masking function is applied to the block of 7104 CRC-protected bits $\{u(0), \dots, u(7103)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(7103)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 7095$ and $u'(i + 7096) = u(i + 7096) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 7104 bits $\{u'(0), \dots, u'(7103)\}$ is delivered to the encoder.

The 7104 bits $\{u'(0), \dots, u'(7103)\}$ are encoded via the rate 0,818 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 8688 coded bits $\{b(0), \dots, b(8687)\}$.

9.1.8.13 16APSK Rate 0,900 LDPC Coding

A 8-bit CRC is applied to the 7984 message bits d_0 to d_{7983} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 7983$. An 8-bit masking function is applied to the block of 7992 CRC-protected bits $\{u(0), \dots, u(7991)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(7991)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 7983$ and $u'(i + 7984) = u(i + 7984) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 7992 bits $\{u'(0), \dots, u'(7991)\}$ is delivered to the encoder.

The 7992 bits $\{u'(0), \dots, u'(7991)\}$ are encoded via the rate 0,900 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 8880 coded bits $\{b(0), \dots, b(8879)\}$.

9.1.8.14 32APSK Rate 0,765 LDPC Coding

A 8-bit CRC is applied to the 8304 message bits d_0 to d_{8303} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 8303$. An 8-bit masking function is applied to the block of 8312 CRC-protected bits $\{u(0), \dots, u(8311)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(8311)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 8303$ and $u'(i + 8304) = u(i + 8304) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 8312 bits $\{u'(0), \dots, u'(8311)\}$ is delivered to the encoder.

The 8312 bits $\{u'(0), \dots, u'(8311)\}$ are encoded via the rate 0,765 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 10860 coded bits $\{b(0), \dots, b(10859)\}$.

9.1.8.15 32APSK Rate 0,818 LDPC Coding

A 8-bit CRC is applied to the 8872 message bits d_0 to d_{8871} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 8871$. An 8-bit masking function is applied to the block of 8880 CRC-protected bits $\{u(0), \dots, u(8879)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(8879)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 8871$ and $u'(i + 8872) = u(i + 8872) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 8880 bits $\{u'(0), \dots, u'(8879)\}$ is delivered to the encoder.

The 8880 bits $\{u'(0), \dots, u'(8879)\}$ are encoded via the rate 0,818 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 10860 coded bits $\{b(0), \dots, b(10859)\}$.

9.1.8.16 Interleaving

Interleaving is performed for 16APSK and 32APSK as described in clause 4.10.3. For $\pi/4$ QPSK modulation, there is no interleaving.

9.1.8.17 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.9 LDPC Coded Packet Normal Burst PNB2(5,3)

The information rate supported by the LDPC coded PNB2(5,3) depends on the modulation and the channel coding used. Modulations include 32APSK, 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates include 1/2, 2/3, 3/4, 4/5, and 9/10.

9.1.9.1 $\pi/4$ QPSK Rate 0,509 LDPC Coding

A 8-bit CRC is applied to the 480 message bits d_0 to d_{479} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 479$. An 8-bit masking function is applied to the block of 488 CRC-protected bits $\{u(0), \dots, u(487)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(487)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 479$ and $u'(i + 480) = u(i + 480) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 488 bits $\{u'(0), \dots, u'(487)\}$ is delivered to the encoder.

The 856 bits $\{u'(0), \dots, u'(487)\}$ are encoded via the rate 0,509 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$.

9.1.9.2 $\pi/4$ QPSK Rate 0,660 LDPC Coding

A 8-bit CRC is applied to the 624 message bits d_0 to d_{623} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 623$. An 8-bit masking function is applied to the block of 632 CRC-protected bits $\{u(0), \dots, u(631)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(631)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 623$ and $u'(i + 624) = u(i + 624) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 632 bits $\{u'(0), \dots, u'(631)\}$ is delivered to the encoder.

The 632 bits $\{u'(0), \dots, u'(631)\}$ are encoded via the rate 0,660 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$.

9.1.9.3 $\pi/4$ QPSK Rate 0,793 LDPC Coding

A 8-bit CRC is applied to the 752 message bits d_0 to d_{751} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 751$. An 8-bit masking function is applied to the block of 760 CRC-protected bits $\{u(0), \dots, u(759)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(759)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 751$ and $u'(i + 752) = u(i + 752) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 760 bits $\{u'(0), \dots, u'(759)\}$ is delivered to the encoder.

The 760 bits $\{u'(0), \dots, u'(759)\}$ are encoded via the rate 0,793 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$.

9.1.9.4 $\pi/4$ QPSK Rate 0,894 LDPC Coding

A 8-bit CRC is applied to the 848 message bits d_0 to d_{847} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 847$. An 8-bit masking function is applied to the block of 856 CRC-protected bits $\{u(0), \dots, u(855)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(855)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 847$ and $u'(i + 848) = u(i + 848) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 856 bits $\{u'(0), \dots, u'(855)\}$ is delivered to the encoder.

The 856 bits $\{u'(0), \dots, u'(855)\}$ are encoded via the rate 0,894 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$.

9.1.9.5 16APSK Rate 0,664 LDPC Coding

A 8-bit CRC is applied to the 1264 message bits d_0 to d_{1263} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1263$. An 8-bit masking function is applied to the block of 1272 CRC-protected bits $\{u(0), \dots, u(1271)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1271)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1263$ and $u'(i + 1264) = u(i + 1264) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1272 bits $\{u'(0), \dots, u'(1271)\}$ is delivered to the encoder.

The 1272 bits $\{u'(0), \dots, u'(1271)\}$ are encoded via the rate 0,664 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 1916 coded bits $\{b(0), \dots, b(1915)\}$.

9.1.9.6 16APSK Rate 0,797 LDPC Coding

A 8-bit CRC is applied to the 1520 message bits d_0 to d_{1519} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1519$. An 8-bit masking function is applied to the block of 1528 CRC-protected bits $\{u(0), \dots, u(1527)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1527)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1519$ and $u'(i + 1520) = u(i + 1520) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1528 bits $\{u'(0), \dots, u'(1527)\}$ is delivered to the encoder.

The 1528 bits $\{u'(0), \dots, u'(1527)\}$ are encoded via the rate 0,797 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 1916 coded bits $\{b(0), \dots, b(1915)\}$.

9.1.9.7 16APSK Rate 0,898 LDPC Coding

A 8-bit CRC is applied to the 1712 message bits d_0 to d_{1711} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1711$. An 8-bit masking function is applied to the block of 1720 CRC-protected bits $\{u(0), \dots, u(1719)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1720)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1711$ and $u'(i + 1712) = u(i + 1712) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1720 bits $\{u'(0), \dots, u'(1719)\}$ is delivered to the encoder.

The 1720 bits $\{u'(0), \dots, u'(1719)\}$ are encoded via the rate 0,898 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 1916 coded bits $\{b(0), \dots, b(1915)\}$.

9.1.9.8 32APSK Rate 0,748 LDPC Coding

A 8-bit CRC is applied to the 1784 message bits d_0 to d_{1783} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1783$. An 8-bit masking function is applied to the block of 1792 CRC-protected bits $\{u(0), \dots, u(1791)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1792)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1783$ and $u'(i + 1784) = u(i + 1784) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1792 bits $\{u'(0), \dots, u'(1791)\}$ is delivered to the encoder.

The 1792 bits $\{u'(0), \dots, u'(1791)\}$ are encoded via the rate 0,748 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 2395 coded bits $\{b(0), \dots, b(2394)\}$.

9.1.9.8a 32APSK Rate 0,798 LDPC Coding

A 8-bit CRC is applied to the 1904 message bits d_0 to d_{1903} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1903$. An 8-bit masking function is applied to the block of 1912 CRC-protected bits $\{u(0), \dots, u(1911)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1912)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1903$ and $u'(i + 1904) = u(i + 1904) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1912 bits $\{u'(0), \dots, u'(1911)\}$ is delivered to the encoder.

The 1912 bits $\{u'(0), \dots, u'(1911)\}$ are encoded via the rate 0,798 LDPC code. The code is defined by the generator polynomial specified in clause 4.10. The encoding results in a block of 2395 coded bits $\{b(0), \dots, b(2394)\}$.

9.1.9.9 Interleaving

Interleaving is performed for 16APSK and 32APSK as described in clause 4.10.3. For $\pi/4$ QPSK modulation, there is no interleaving.

9.1.9.10 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.10 Packet Normal Burst PNB3(1,3)

PNB3(1,3) is intended to carry either encoded speech or user packet data over DCH (Dedicated channel). PNB3(1,3) supports two pair of speech and data rates.

- 2,45 kbps voice speech or 2,6 kbps data;
- 4,0 kbps voice speech or 4,0 kbps data.

9.1.10.1 PNB3(1,3) 2,45 kbps speech

Channel coding rates of approximately 7/13, and 8/13 are defined for the PNB3(1,3) 2,45 kbps voice channel. PNB3(1,3) 2,45 kbps consists of 48 perceptually important bits, 50 perceptually unimportant bits, 5 CRC bits and 7 control bits that provides, in total, a payload for 194 coded bits.

9.1.10.1.1 Channel coding

A total of 7 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 48 perceptually important message bits d_0 to d_{47} . A 5-bit CRC, as specified in clause 4.3, is generated for the 55 ($= 48 + 7$) information and control bits. The 5 CRC bits are appended at the end of the information and control bits to obtain a total of 60 bits $\{u'(0), \dots, u'(59)\}$ which are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 120 coded bits $\{b(0), \dots, b(119)\}$.

Puncturing is performed using the puncture mask $P(1;7)$, as listed in table 4.7. This action turns out that 8 bits in $\{b\}$ with index $14k + 1$ ($k = 0, \dots, 7$) are punctured out. The result is a block of 112 coded bits $\{c(0), \dots, c(111)\}$.

There are 50 perceptually unimportant bits in PNB3(1,3) 2,45 kbps that are encoded via the rate 1/2 tail-biting convolutional encoder with constraint length $K = 5$ as specified in clause 4.4.5. Encoding results in a block of 100 coded bits, $\{b'(0), \dots, b'(99)\}$, that are punctured using $P(3,8)$ as listed in table 4.3. This action turns out that 18 bits in $\{b'\}$ with index $16k, 16k + 4, 16k + 13$ ($k = 0, \dots, 5$) are punctured out. The result is a block of 82 coded bits $\{c'(0), \dots, c'(81)\}$.

9.1.10.1.2 Interleaving

Intraburst interleaving is performed on the coded block corresponding to the perceptually important bits. The interleaving pattern is as defined in clause 4.8.1.

Intraburst interleaving is also performed separately on the coded block corresponding to the perceptually unimportant bits. The interleaving pattern is as defined in clause 4.8.1.

9.1.10.1.3 Scrambling

The interleaved version of the perceptually unimportant bits are appended at the end of the interleaved version of perceptually important bits to form a single block. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on this single block.

9.1.10.2 PNB3(1,3) 2,6 kbps data over DCH (Dedicated Channel)

The channel coding rate supported by the PNB3(1,3) for data over DCH is approximately 7/13. PNB3(1,3) for the data channel consists of 88 data bits and 16 CRC bits that provides, in total, a payload for 194 coded bits.

9.1.10.2.1 Channel coding

A total of 5 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 83 data bits d_0 to d_{82} . A 16-bit CRC is applied to the 88 (83 + 5) data and control bits d_0 to d_{87} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 87$. The resultant 104 bits $\{u'(0), \dots, u'(103)\}$ are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 208 coded bits $\{b(0), \dots, b(207)\}$.

Puncturing is performed using the puncture mask P(1;7), as listed in table 4.7. This action turns out that 14 bits in $\{b\}$ with index $14k + 1$ ($k = 0, \dots, 13$) are punctured out. The result is a block of 194 coded bits $\{c(0), \dots, c(193)\}$.

9.1.10.2.2 Interleaving

Intraburst interleaving is performed on the coded block. The interleaving pattern is as defined in clause 4.8.1.

9.1.10.2.3 Scrambling

Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on the interleaved version of the coded block.

9.1.10.3 PNB3(1,3) 4 kbps Speech

The information rate supported by the PNB3(1,3), 4 kbps, VoIP depends on the channel coding used. Channel coding rates of approximately 5/6 is defined for the PNB(1,3) 4 kbps. PNB3(1,3) (4 kbps) consists of 96 perceptually important bits, 64 perceptually unimportant bits, 5 CRC bits and 7 control bits that provides, in total, a payload for 194 coded bits.

9.1.10.3.1 Channel coding

A total of 7 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 96 perceptually important message bits d_0 to d_{95} . A 5-bit CRC, as specified in clause 4.3, is generated for the 103 (= 96 + 7) information and control bits. The 5 CRC bits are appended at the end of the information and control bits to obtain a total of 108 bits $\{u'(0), \dots, u'(107)\}$ which are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 216 coded bits $\{b(0), \dots, b(215)\}$.

Puncturing is performed using the puncture mask P(4;5), as listed in table 4.7. This action turns out that 84 bits in $\{b\}$ with index $10k$, $10k + 4$, $10k + 7$, $10k + 9$ ($k = 0, \dots, 20$) are punctured out. After applying P(4;5), two more bits with index 210 and 214 are also punctured. The result is a block of 130 coded bits $\{c(0), \dots, c(129)\}$.

The 64 perceptually unimportant bits in PNB3(1,3) for 4 kbps are not coded or punctured.

9.1.10.3.2 Interleaving

Intraburst interleaving is performed on the coded block corresponding to the perceptually important bits. The interleaving pattern is as defined in clause 4.8.1.

Intraburst interleaving is also performed separately on the block corresponding to the perceptually unimportant bits. The interleaving pattern is as defined in clause 4.8.1.

9.1.10.3.3 Scrambling

The interleaved version of the perceptually unimportant bits are appended at the end of the interleaved version of perceptually important bits to form a single block. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on this single block.

9.1.10.4 PNB3(1,3) 4 kbps data over DCH (Dedicated Channel)

The channel coding rate supported by the PNB3(1,3) 4kbps for data over DCH is approximately 4/5. PNB3(1,3) 4kbps for data channel consists of 144 data bits and 16 CRC bits that provides, in total, a payload for 194 coded bits.

9.1.10.4.1 Channel coding

A total of 5 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 139 data bits d_0 to d_{138} . A 16-bit CRC is applied to the 144 (139 + 5) data and control bits as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 143$. The resultant 160 bits $\{u'(0), \dots, u'(159)\}$ are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.5, where the constraint length $K = 9$ is used. The encoding results in a block of 320 coded bits $\{b(0), \dots, b(319)\}$.

Puncturing is performed using the puncture mask P2(3;4), as listed in table 4.7. This action turns out that 120 bits in $\{b\}$ with index $8k + 1$, $8k + 2$, $8k + 5$ ($k = 0, \dots, 39$) are punctured out. After applying P(3;4), six more bits with index 7, 15, 23, 303, 311, 319 are also punctured. The result is a block of 194 coded bits $\{c(0), \dots, c(193)\}$.

9.1.10.4.2 Interleaving

Intraburst interleaving is performed on the coded block. The interleaving pattern is as defined in clause 4.8.1.

9.1.10.4.3 Scrambling

Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on the interleaved version of the coded block.

9.1.11 Packet Normal Burst PNB3(1,6)

PNB3(1,6) is intended to carry either encoded speech or user packet data over DCH (Dedicated Channel). PNB3(1,6) supports two pair of speech and data rates.

- 2,45 kbps voice speech or 2,6 kbps data;
- 4,0 kbps voice speech or 4,0 kbps data.

9.1.11.1 PNB3(1,6) 2,45 kbps Speech

The information rate supported by the PNB3(1,6), 2,45 kbps VoIP depends on the channel coding used. Channel coding rates of approximately 9/17, and 6/10 are defined for the PNB3(1,6), 2,45 kbps. PNB3(1,6), 2,45 kbps consists of 48 perceptually important bits, 50 perceptually unimportant bits, 5 CRC bits and 7 control bits that provides, in total, a payload for 198 coded bits.

9.1.11.1.1 Channel coding

A total of 7 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 48 perceptually important message bits d_0 to d_{47} . A 5-bit CRC, as specified in clause 4.3, is generated for the 55 (= 48 + 7) information and control bits. The 5 CRC bits are appended at the end of the information and control bits to obtain a total of 60 bits $\{u'(0), \dots, u'(59)\}$ which are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6. where the constraint length $K = 9$ is used. The encoding results in a block of 120 coded bits $\{b(0), \dots, b(119)\}$.

Puncturing is performed using the puncture mask $P(1;9)$, as listed in table 4.7. This action turns out that 6 bits in $\{b\}$ with index $18k$ ($k = 0, \dots, 5$) are punctured out. The result is a block of 114 coded bits $\{c(0), \dots, c(113)\}$.

There are 50 perceptually unimportant bits in PNB3(1,6) that are encoded via the rate 1/2 tail-biting convolutional encoder with constraint length $K = 5$ as specified in clause 4.4.5. Encoding results in a block of 100 coded bits, $\{b'(0), \dots, b'(99)\}$ that are punctured using $P(2;6)$ as listed in table 4.3. This action turns out that 16 bits in $\{b'\}$ with index $12k + 1, 12k + 7$ ($k = 0, \dots, 7$) are punctured out. The result is a block of 84 coded bits $\{c'(0), \dots, c'(83)\}$.

9.1.11.1.2 Interleaving

Intraburst interleaving is performed on the coded block corresponding to the perceptually important bits. The interleaving pattern is as defined in clause 4.8.1.

Intraburst interleaving is also performed separately on the coded block corresponding to the perceptually unimportant bits. The interleaving pattern is as defined in clause 4.8.1.

9.1.11.1.3 Scrambling

The interleaved version of the perceptually unimportant bits are appended at the end of the interleaved version of perceptually important bits to form a single block. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on this single block.

9.1.11.2 PNB3(1,6) 2,6 kbps Data over DCH (Dedicated channel)

The channel coding rate supported by the PNB3(1,6) for data over DCH is approximately 10/19. PNB3(1,6) for data channel consists of 88 data bits and 16 CRC bits that provides, in total, a payload for 198 coded bits.

9.1.11.2.1 Channel coding

A total of 5 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 83 data bits d_0 to d_{82} . A 16-bit CRC is applied to the 88 ($83 + 5$) data and control bits d_0 to d_{87} as specified in clause 4.3, where $d(i) = d_i, i = 0, \dots, 87$. The resultant 104 bits $\{u'(0), \dots, u'(103)\}$ are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 208 coded bits $\{b(0), \dots, b(207)\}$.

Puncturing is performed using the puncture mask $P(1;10)$, as listed in table 4.7. This action turns out that 10 bits in $\{b\}$ with index $20k$ ($k = 0, \dots, 9$) are punctured out. The result is a block of 198 coded bits $\{c(0), \dots, c(197)\}$.

9.1.11.2.2 Interleaving

Intraburst interleaving is performed on the coded block. The interleaving pattern is as defined in clause 4.8.1.

9.1.11.2.3 Scrambling

Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on the interleaved version of the coded block.

9.1.11.3 PNB3(1,6) 4 kbps Speech

The information rate supported by the PNB3(1,6) 4 kbps VoIP depends on the channel coding used. Channel coding rates of approximately 8/17, and 2/5 are defined for the PNB3(1,6), 4 kbps. PNB3(1,6), 4kbps consists of 96 perceptually important bits, 64 perceptually unimportant bits, 5 CRC bits and 7 control bits that provides, in total, a payload for 396 coded bits.

9.1.11.3.1 Channel coding

A total of 7 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 96 perceptually important message bits d_0 to d_{95} . A 5-bit CRC, as specified in clause 4.3, is generated for the 103 (= 96 + 7) information and control bits. The 5 CRC bits are appended at the end of the information and control bits to obtain a total of 108 bits $\{u'(0), \dots, u'(107)\}$ which are encoded via the rate 1/3 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.9. The encoding results in a block of 324 coded bits $\{b(0), \dots, b(323)\}$.

Puncturing is performed using the puncture mask P(1;2), as listed in table 4.7c. This action turns out that 54 bits in $\{b\}$ with index $6k + 3$, ($k = 0, \dots, 53$) are punctured out. The result is a block of 270 coded bits. Additionally, bits with index 1, 5, 317 and 319 are punctured to obtain a block of 266 coded bits $\{c(0), \dots, c(265)\}$.

There are 64 perceptually unimportant bits in PNB3(1,6) 4 kbps that are encoded via the rate 1/3 tail-biting convolutional encoder. The code is defined by the generator polynomial specified in clause 4.4.7. Encoding results in 192 coded bits $\{b'(0), \dots, b'(191)\}$ that are punctured using P(7;8) as listed in table 4.4. This action turns out that 56 bits in $\{b'\}$ with index $24k, 24k + 1, 24k + 5, 24k + 9, 24k + 17, 24k + 19, 24k + 22$, ($k = 0, \dots, 7$) are punctured out. The result is a block of 136 coded bits. Additionally, bits with index 3, 7, 11, 179, 181, and 183 are punctured to obtain a block of 130 coded bits $\{c'(0), \dots, c'(129)\}$.

9.1.11.3.2 Interleaving

Intraburst interleaving is performed on the coded block corresponding to the perceptually important bits. The interleaving pattern is as defined in clause 4.8.1.

Intraburst interleaving is also performed separately on the coded block corresponding to the perceptually unimportant bits. The interleaving pattern is as defined in clause 4.8.1.

9.1.11.3.3 Scrambling

The interleaved version of the perceptually unimportant bits are appended at the end of the interleaved version of perceptually important bits to form a single block. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on this single block.

9.1.11.4 PNB3(1,6) 4 kbps Data over DCH (Dedicated Channel)

The channel coding rate supported by the PNB3(1,6), 4 kbps for data over DCH is approximately 2/5. PNB3(1,6) 4 kbps for data channel consists of 144 data bits and 16 CRC bits that provides, in total, a payload for 396 coded bits.

9.1.11.4.1 Channel coding

A total of 5 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 139 data bits d_0 to d_{138} . A 16-bit CRC is applied to the 144 (139 + 5) data and control bits d_0 to d_{143} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 143$. The resultant 160 bits $\{u'(0), \dots, u'(159)\}$ are encoded via the rate 1/3 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.9, where the constraint length $K = 9$ is used. The encoding results in a block of 480 coded bits $\{b(0), \dots, b(479)\}$.

Puncturing is performed using the puncture mask P(1;2), as listed in table 4.7c. This action turns out that 54 bits in $\{b\}$ with index $6k + 3$, ($k = 0, \dots, 79$) are punctured out. The result is a block of 400 coded bits. Additionally, bits with index 1, 5, 473, and 475 are punctured to obtain a coded block of 396 bits $\{c(0), \dots, c(395)\}$.

9.1.11.4.2 Interleaving

Intraburst interleaving is performed on the coded block. The interleaving pattern is as defined in clause 4.8.1.

9.1.11.4.3 Scrambling

Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on the interleaved version of the coded block.

9.1.12 Packet Normal Burst PNB3(1,8)

PNB3(1,8) is intended to carry either encoded speech or user packet data over DCH (Dedicated channel). PNB3(1,8) supports a pair of speech and data rate.

- 4,0 kbps voice speech or 4 kbps data.

9.1.12.1 PNB3(1,8) 4 kbps speech

The information rate supported by the PNB3(1,8) 4 kbps VoIP depends on the channel coding used. Channel coding rates of approximately 4/7, and 2/3 are defined for the PNB(1,8). PNB3(1,8) consists of 96 perceptually important bits, 64 perceptually unimportant bits, 5 CRC bits and 7 control bits that provides, in total, a payload for 280 coded bits.

9.1.12.1.1 Channel coding

A total of 7 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 96 perceptually important message bits d_0 to d_{95} . A 5-bit CRC, as specified in clause 4.3, is generated for the 103 (= 96 + 7) information and control bits. The 5 CRC bits are appended at the end of the information and control bits to obtain a total of 108 bits $\{u'(0), \dots, u'(107)\}$ which are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 216 coded bits $\{b(0), \dots, b(215)\}$.

Puncturing is performed using the puncture mask $P(1;4)$, as listed in table 4.7. This action turns out that 27 bits in $\{b\}$ with index $8k + 1$ ($k = 0, \dots, 26$) are punctured out. After applying $P(1;4)$, three more bits with index 3, 5 and 214 are also punctured. The result is a block of 186 coded bits $\{c(0), \dots, c(185)\}$.

There are 64 perceptually unimportant bits in PNB3(1,8) that are encoded via the rate 1/2 tail-biting convolutional encoder with constraint length $K = 5$ as specified in clause 4.4.5. Encoding results in a block of 128 coded bits, $\{b'(0), \dots, b'(127)\}$ that are punctured using $P^*(1;2)$ as listed in table 4.3. This action turns out that 32 bits in $\{b'\}$ with index $4k + 1$, ($k = 0, \dots, 31$) are punctured out. After applying $P^*(1;2)$, two more bit with index 3 and 123 are also punctured. The result is a block of 94 coded bits $\{c'(0), \dots, c'(93)\}$.

9.1.12.1.2 Interleaving

Intraburst interleaving is performed on the coded block corresponding to the perceptually important bits. The interleaving pattern is as defined in clause 4.8.1.

Intraburst interleaving is also performed separately on the coded block corresponding to the perceptually unimportant bits. The interleaving pattern is as defined in clause 4.8.1.

9.1.12.1.3 Scrambling

The interleaved version of the perceptually unimportant bits are appended at the end of the interleaved version of perceptually important bits to form a single block. Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on this single block.

9.1.12.2 PNB3(1,8) 4 kbps data over DCH(Dedicated Channel)

The channel coding rate supported by the PNB3(1,8) for data over DCH is approximately 4/7. PNB3(1,8) for data channel consists of 144 data bits and 16 CRC bits that provides, in total, a payload for 280 coded bits.

9.1.12.2.1 Channel coding

A total of 5 control bits consisting of status field bits defined in clause 7.2 are appended at the end of the 139 data bits d_0 to d_{138} . A 16-bit CRC is applied to the 144 (139 + 5) data and control bits d_0 to d_{143} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 143$. The resultant 160 bits $\{u'(0), \dots, u'(159)\}$ are encoded via the rate 1/2 tail-biting convolutional code. The code is defined by the generator polynomial specified in clause 4.4.6, where the constraint length $K = 9$ is used. The encoding results in a block of 320 coded bits $\{b(0), \dots, b(319)\}$.

Puncturing is performed using the puncture mask $P(1;4)$, as listed in table 4.7. This action turns out that 40 bits in $\{b\}$ with index $8k + 1$ ($k = 0, \dots, 39$) are punctured out. The result is a block of 280 coded bits $\{c(0), \dots, c(279)\}$.

9.1.12.2.2 Interleaving

Intraburst interleaving is performed on the coded block. The interleaving pattern is as defined in clause 4.8.1.

9.1.12.2.3 Scrambling

Scrambling, as defined in clause 4.9 of GMR-1 05.003 [3], is performed on the interleaved version of the coded block.

9.1.13 Packet Normal Burst PNB3(2,6)/uplink

The information rate supported by the PNB3(2,6) in the uplink depends on the channel coding used. Channel coding rates of approximately 3/5, 7/10, and 4/5 are defined for the PNB3(2,6) in the uplink. Independent of channel coding rate, the PNB3(2,6) provides a common payload for 800 coded bits.

9.1.13.1 Rate 3/5 Turbo coding

A 16-bit CRC is applied to the 456 message bits d_0 to d_{455} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 455$. An 8-bit masking function is applied to the block of 472 CRC-protected bits $\{u(0), \dots, u(471)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(471)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 463$ and $u'(i + 464) = u(i + 464) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 472 bits $\{u'(0), \dots, u'(471)\}$ is delivered to the encoder.

The 472 bits $\{u'(0), \dots, u'(471)\}$ are encoded via the rate 1/5 turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2372 coded bits. The puncturing matrix $P(10;3)$ as shown in table 4.29 d is applied on the 2372 coded bits. This results in 799 coded bits. Additionally bit 2358 is depunctured. The result is a block of 800 coded bits $\{c(0), \dots, c(799)\}$.

9.1.13.2 Rate 7/10 Turbo coding

A 16-bit CRC is applied to the 544 message bits d_0 to d_{543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 543$. An 8-bit masking function is applied to the block of 560 CRC-protected bits $\{u(0), \dots, u(559)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(559)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 551$ and $u'(i + 552) = u(i + 552) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 560 bits $\{u'(0), \dots, u'(559)\}$ is delivered to the encoder.

The 560 bits $\{u'(0), \dots, u'(559)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2812 coded bits. The puncturing matrix $P(50;14)$ as shown in table 4.29d is applied on the 2812 coded bits. This results in 812 coded bits. A second stage of puncturing as defined by P8 in table 4.29f is then applied. The result is a block of 800 coded bits $\{c(0), \dots, c(799)\}$.

9.1.13.3 Rate 4/5 Turbo coding

A 16-bit CRC is applied to the 624 message bits d_0 to d_{623} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 623$. An 8-bit masking function is applied to the block of 640 CRC-protected bits $\{u(0), \dots, u(639)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(639)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 631$ and $u'(i + 632) = u(i + 632) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 640 bits $\{u'(0), \dots, u'(639)\}$ is delivered to the encoder.

The 640 bits $\{u'(0), \dots, u'(639)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 3212 coded bits. The puncturing matrix P(30;8) as shown in table 4.29d is applied on the 3212 coded bits. This results in 812 coded bits. A second stage of puncturing as defined by P9 in table 4.29f is then applied. The result is a block of 800 coded bits $\{c(0), \dots, c(799)\}$.

9.1.13.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.13.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.14 Packet Normal Burst PNB3(2,6)/downlink

The information rate supported by the PNB3(2,6) in the downlink depends on the channel coding used. Channel coding rates of approximately 3/5, 7/10, and 4/5 are defined for the PNB3(2,6) in the downlink. Independent of channel coding rate, the PNB3(2,6) provides a common payload for 778 coded bits.

9.1.14.1 Rate 3/5 Turbo coding

A 16-bit CRC is applied to the 456 message bits d_0 to d_{455} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 455$. An 8-bit masking function is applied to the block of 472 CRC-protected bits $\{u(0), \dots, u(471)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(471)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 463$ and $u'(i + 464) = u(i + 464) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 472 bits $\{u'(0), \dots, u'(471)\}$ is delivered to the encoder.

The 472 bits $\{u'(0), \dots, u'(471)\}$ are encoded via the rate 1/5 turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2372 coded bits. The puncturing matrix P(54;16) as shown in table 4.29d is applied on the 2372 coded bits. This results in 780 coded bits. A second stage of puncturing as defined by P10 in table 4.29f is then applied. The result is a block of 778 coded bits $\{c(0), \dots, c(777)\}$.

9.1.14.2 Rate 7/10 Turbo coding

A 16-bit CRC is applied to the 544 message bits d_0 to d_{543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 543$. An 8-bit masking function is applied to the block of 560 CRC-protected bits $\{u(0), \dots, u(559)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(559)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 551$ and $u'(i + 552) = u(i + 552) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 560 bits $\{u'(0), \dots, u'(559)\}$ is delivered to the encoder.

The 560 bits $\{u'(0), \dots, u'(559)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2812 coded bits. The puncturing matrix P(58;16) as shown in table 4.29d is applied on the 2812 coded bits. This results in 782 coded bits. A second stage of puncturing as defined by P11 in table 4.29f is then applied. The result is a block of 778 coded bits $\{c(0), \dots, c(777)\}$.

9.1.14.3 Rate 4/5 Turbo coding

A 16-bit CRC is applied to the 624 message bits d_0 to d_{623} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 623$. An 8-bit masking function is applied to the block of 640 CRC-protected bits $\{u(0), \dots, u(639)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 16 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(639)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 631$ and $u'(i + 632) = u(i + 632) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 640 bits $\{u'(0), \dots, u'(639)\}$ is delivered to the encoder.

The 640 bits $\{u'(0), \dots, u'(639)\}$ are encoded via the rate 1/5 turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 3212 coded bits. The puncturing matrix P(38;10) as shown in table 4.29d is applied on the 3212 coded bits. This results in 780 coded bits. A second stage of puncturing as defined by P12 in table 4.29f is then applied. The result is a block of 778 coded bits $\{c(0), \dots, c(777)\}$.

9.1.14.4 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.1.14.5 Scrambling, multiplexing, and encryption

Scrambling is performed as described in clause 4.9. No encryption is performed.

9.1.15 PNB3 (5,3) burst

The information rate supported by the Turbo coded PNB3(5,3) depends on the modulation and the channel coding used. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.15.1 $\pi/4$ QPSK PNB3(5,3) Rate 1/2

9.1.15.1.1 Channel coding

A 16-bit CRC is applied to the 464 message bits d_0 to d_{463} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 463$. An 8-bit masking function is applied to the block of 480 CRC-protected bits $\{u(0), \dots, u(479)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(479)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 471$ and $u'(i + 472) = u(i + 472) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 480 bits $\{u'(0), \dots, u'(479)\}$ is delivered to the encoder.

The 480 bits $\{u'(0), \dots, u'(479)\}$ are encoded via the rate 1/5 Turbo code as specified in 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2412 coded bits. The puncturing matrix P(6;2) as shown in table 4.29d is applied on the 2412 coded bits. This results in 972 coded bits. A second stage of puncturing as defined by P1 for PNB3(5,3) in table 4.29e is then applied. This operation results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$ with an approximate coding rate of 0,501.

9.1.15.1.2 Interleaving

Same as clause 4.8.1.

9.1.15.1.3 Scrambling

Same as clause 4.9.

9.1.15.2 $\pi/4$ QPSK PNB3(5,3) Rate 5/8

9.1.15.2.1 Channel coding

A 16-bit CRC is applied to the 584 message bits d_0 to d_{583} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 583$. An 8-bit masking function is applied to the block of 600 CRC-protected bits $\{u(0), \dots, u(599)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(599)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 591$ and $u'(i + 592) = u(i + 592) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 600 bits $\{u'(0), \dots, u'(599)\}$ is delivered to the encoder.

The 600 bits $\{u'(0), \dots, u'(599)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 3 012 coded bits. The puncturing matrix P(34;10) as shown in table 4.29d is applied on the 3 012 coded bits. This results in 972 coded bits. A second stage of puncturing as defined by P2 for PNB3(5,3) in table 4.29e is then applied. This operation results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$ with an approximate coding rate of 0,626.

9.1.15.3 $\pi/4$ QPSK PNB3(5,3) Rate 3/4

9.1.15.3.1 Channel Coding

A 16-bit CRC is applied to the 704 message bits d_0 to d_{703} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 703$. An 8-bit masking function is applied to the block of 720 CRC-protected bits $\{u(0), \dots, u(719)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(719)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 711$ and $u'(i + 712) = u(i + 712) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 720 bits $\{u'(0), \dots, u'(719)\}$ is delivered to the encoder.

The 720 bits $\{u'(0), \dots, u'(719)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 3612 coded bits. The puncturing matrix P(22;6) as shown in table 4.29d is applied on the 3612 coded bits. This results in 972 coded bits. A second stage of puncturing as defined by P3 for PNB3(5,3) in table 4.29e is then applied. This operation results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$ with an approximate coding rate of 0,752.

9.1.15.4.1 Channel coding

A 16-bit CRC is applied to the 784 message bits d_0 to d_{783} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 783$. An 8-bit masking function is applied to the block of 800 CRC-protected bits $\{u(0), \dots, u(719)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(799)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 791$ and $u'(i + 792) = u(i + 792) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 800 bits $\{u'(0), \dots, u'(799)\}$ is delivered to the encoder.

The 800 bits $\{u'(0), \dots, u'(799)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 4012 coded bits. The puncturing matrix P(38;10) as shown in table 4.29d is applied on the 4 012 coded bits. This results in 972 coded bits. A second stage of puncturing as defined by P4 for PNB3(5,3) in table 4.29e is then applied. This operation results in a block of 958 coded bits $\{b(0), \dots, b(957)\}$ with an approximate coding rate of 0,835.

9.1.15.4.2 Interleaving

Same as clause 4.8.1.

9.1.15.4.3 Scrambling

Same as clause 4.9.

9.1.15.5 16APSK PNB3(5,3) Rate 2/3

9.1.15.5.1 Channel coding

A 16-bit CRC is applied to the 1264 message bits d_0 to d_{1263} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1263$. An 8-bit masking function is applied to the block of 1280 CRC-protected bits $\{u(0), \dots, u(1279)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1279)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1271$ and $u'(i + 1272) = u(i + 1272) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1280 bits $\{u'(0), \dots, u'(1279)\}$ is delivered to the encoder.

The 1280 bits $\{u'(0), \dots, u'(1279)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 6 412 coded bits. The puncturing matrix P(14;4) as shown in table 4.29d is applied on the 6 412 coded bits. This results in 1932 coded bits. A second stage of puncturing as defined by P5 for PNB3(5,3) in table 4.29e is then applied. This operation results in a block of 1 916 coded bits $\{b(0), \dots, b(1915)\}$ with an approximate coding rate of 0,668.

9.1.15.5.2 Interleaving

The 1916 coded bits are serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(5,3) 16APSK, the block interleaver has 479 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.15.5.3 Scrambling

Same as clause 4.9.

9.1.16 PNB3 (5,3) burst carrying ULMAP

The information rate supported by the Turbo coded PNB3(5,3) burst in the downlink carrying a ULMAP depends on the modulation and the channel coding used. The ULMAP for PNB3(5,3) contains 128 coded bits. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.16.1 $\pi/4$ QPSK PNB3(5,3) Rate 1/2 burst carrying ULMAP

9.1.16.1.1 Channel coding

A 16-bit CRC is applied to the 392 message bits d_0 to d_{391} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 391$. An 8-bit masking function is applied to the block of 408 CRC-protected bits $\{u(0), \dots, u(407)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(407)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 399$ and $u'(i + 400) = u(i + 400) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 408 bits $\{u'(0), \dots, u'(407)\}$ is delivered to the encoder.

The 408 bits $\{u'(0), \dots, u'(407)\}$ are encoded via the rate 1/5 Turbo code as specified in 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2052 coded bits. The puncturing matrix $P(6;2)$ as shown in table 4.29d is applied on the 2052 coded bits. This results in 828 coded bits. A second stage of depuncturing as defined by D1 for PNB3(5,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 830 coded bits $\{b(0), \dots, b(829)\}$ with an approximate coding rate of 0,492.

9.1.16.1.2 Interleaving

Same as clause 4.8.1.

9.1.16.1.3 Scrambling

Same as clause 4.9.

9.1.16.2 $\pi/4$ QPSK PNB3(5,3) Rate 5/8 carrying ULMAP

9.1.16.2.1 Channel coding

A 16-bit CRC is applied to the 496 message bits d_0 to d_{495} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 495$. An 8-bit masking function is applied to the block of 512 CRC-protected bits $\{u(0), \dots, u(511)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(511)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 503$ and $u'(i + 504) = u(i + 504) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 512 bits $\{u'(0), \dots, u'(511)\}$ is delivered to the encoder.

The 512 bits $\{u'(0), \dots, u'(511)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2572 coded bits. The puncturing matrix $P(10;3)$ as shown in table 4.29d is applied on the 2572 coded bits. This results in 866 coded bits. A second stage of puncturing as defined by P6 for PNB3(5,3) with ULMAP in table 4.29e is then applied. This operation results in a block of 830 coded bits $\{b(0), \dots, b(829)\}$ with an approximate coding rate of 0,616.

9.1.16.2.2 Interleaving

Same as clause 4.8.1.

9.1.16.3 $\pi/4$ QPSK PNB3(5,3) Rate 3/4 carrying ULMAP

9.1.16.3.1 Channel Coding

A 16-bit CRC is applied to the 576 message bits d_0 to d_{575} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 575$. An 8-bit masking function is applied to the block of 592 CRC-protected bits $\{u(0), \dots, u(591)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(591)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 583$ and $u'(i + 584) = u(i + 584) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 592 bits $\{u'(0), \dots, u'(591)\}$ is delivered to the encoder.

The 592 bits $\{u'(0), \dots, u'(591)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 2972 coded bits. The puncturing matrix P(22;6) as shown in table 4.29d is applied on the 2972 coded bits. This results in 800 coded bits. A second stage of depuncturing as defined by D3 for PNB3(5,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 830 coded bits $\{b(0), \dots, b(829)\}$ with an approximate coding rate of 0,713.

9.1.16.4.1 Channel coding

A 16-bit CRC is applied to the 656 message bits d_0 to d_{655} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 655$. An 8-bit masking function is applied to the block of 672 CRC-protected bits $\{u(0), \dots, u(671)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(671)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 663$ and $u'(i + 664) = u(i + 664) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 672 bits $\{u'(0), \dots, u'(671)\}$ is delivered to the encoder.

The 672 bits $\{u'(0), \dots, u'(671)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 3372 coded bits. The puncturing matrix P(38;10) as shown in table 4.29d is applied on the 3372 coded bits. This results in 820 coded bits. A second stage of depuncturing as defined by D4 for PNB3(5,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 830 coded bits $\{b(0), \dots, b(671)\}$ with an approximate coding rate of 0,8096.

9.1.16.4.2 Interleaving

Same as clause 4.8.1.

9.1.16.4.3 Scrambling

Same as clause 4.9.

9.1.16.5 16APSK PNB3(5,3) carrying ULMAP Rate 2/3

9.1.16.5.1 Channel coding

A 16-bit CRC is applied to the 1056 message bits d_0 to d_{1055} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1055$. An 8-bit masking function is applied to the block of 1072 CRC-protected bits $\{u(0), \dots, u(1071)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1071)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1063$ and $u'(i + 1064) = u(i + 1064) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1072 bits $\{u'(0), \dots, u'(1071)\}$ is delivered to the encoder.

The 1072 bits $\{u'(0), \dots, u'(1071)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 5372 coded bits. The puncturing matrix P(14;4) as shown in table 4.29d is applied on the 5372 coded bits. This results in 1620 coded bits. A second stage of depuncturing as defined by D5 for PNB3(5,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 1660 coded bits $\{b(0), \dots, b(1659)\}$ with an approximate coding rate of 0,645.

9.1.16.5.2 Interleaving

The 1660 coded bits are serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(5,3) 16APSK, carrying ULMAP, the block interleaver has 415 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.16.5.3 Scrambling

Same as clause 4.9.

9.1.17 PNB3 (5,12) burst

The information rate supported by the Turbo coded PNB3(5,12) depends on the modulation and the channel coding used. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.17.1 $\pi/4$ QPSK PNB3(5,12) burst Rate 1/2

9.1.17.1.1 Channel coding

A 16-bit CRC is applied to the 2208 message bits d_0 to d_{2207} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2207$. An 8-bit masking function is applied to the block of 2224 CRC-protected bits $\{u(0), \dots, u(2223)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2224)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2215$ and $u'(i + 2216) = u(i + 2216) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2224 bits $\{u'(0), \dots, u'(2223)\}$ is delivered to the encoder.

The 2224 bits $\{u'(0), \dots, u'(2223)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 11132 coded bits. The puncturing matrix P(6;2) as shown in table 4.29d is applied on the 11132 coded bits. This results in 4460 coded bits. A second stage of puncturing as defined by P1 for PNB3(5,12) in table 4.29e is then applied. This operation results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$ with an approximate coding rate of 0,501.

Same as clause 4.9.

9.1.17.4 $\pi/4$ QPSK PNB3(5,12) burst Rate 5/6

9.1.17.4.1 Channel coding

A 16-bit CRC is applied to the 3704 message bits d_0 to d_{3703} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3703$. An 8-bit masking function is applied to the block of 3720 CRC-protected bits $\{u(0), \dots, u(3719)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3719)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3711$ and $u'(i + 3712) = u(i + 3712) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3720 bits $\{u'(0), \dots, u'(3719)\}$ is delivered to the encoder.

The 3720 bits $\{u'(0), \dots, u'(3719)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 18612 coded bits. The puncturing matrix P(38;10) as shown in table 4.29d is applied on the 18612 coded bits. This results in 4476 coded bits. A second stage of puncturing as defined by P4 for PNB3(5,12) in table 4.29e is then applied. This operation results in a block of 4440 coded bits $\{b(0), \dots, b(4439)\}$ with an approximate coding rate of 0,835.

9.1.17.4.2 Interleaving

9.1.17.4.3 Scrambling

Same as clause 4.9.

9.1.17.5 16APSK PNB3(5,12) burst Rate 2/3

9.1.17.5.1 Channel coding

Two blocks of 2944 message bits, $\{d(0), \dots, d(2943)\}$ and $\{d'(0), \dots, d'(2943)\}$ are considered. A 16-bit CRC is applied to each 2944 message block as specified in clause 4.3. An 8-bit masking function is applied to each block of 2960 CRC-protected bits $\{u1(0), \dots, u1(2959)\}$ and $\{u2(0), \dots, u2(2959)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2959)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2951$ and $u'(i + 2952) = u(i + 2952) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant blocks of 2960 bits $\{u'(0), \dots, u'(2959)\}$ and $\{u''(0), \dots, u''(2959)\}$ is delivered to the encoder.

Each of the 2960 bit message block $\{u'(0), \dots, u'(2959)\}$ and $\{u''(0), \dots, u''(2959)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in two blocks of 14812 coded bits. The puncturing matrix P(14;4) as shown in table 4.29d is applied on the 14812 coded bits. This results in two blocks of 4452 coded bits. A second stage of puncturing as defined by P5 for PNB3(5,12) in table 4.29e is then applied. This operation results in a two blocks of 4440 coded bits $\{b(0), \dots, b(4439)\}$ and $\{b'(0), \dots, b'(4439)\}$ with an approximate coding rate of 0,668. The 8880 bits from the two encoders are delivered to the 16APSK modulator.

9.1.17.5.2 Interleaving

The block of 8880 bits is serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(5,12) 16APSK, the block interleaver has 2200 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.17.5.3 Scrambling

Same as clause 4.9.

9.1.18 PNB3(5,12) burst carrying ULMAP

The information rate supported by the Turbo coded PNB3(5,12) burst in the downlink carrying ULMAP depends on the modulation and the channel coding used. The ULMAP for PNB3(5,12) burst has 320 coded bits. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.18.1 $\pi/4$ QPSK PNB3(5,12) Rate 1/2 burst carrying ULMAP

9.1.18.1.1 Channel coding

A 16-bit CRC is applied to the 2024 message bits d_0 to d_{2023} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2023$. An 8-bit masking function is applied to the block of 2040 CRC-protected bits $\{u(0), \dots, u(2039)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2039)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2031$ and $u'(i + 2032) = u(i + 2032) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2040 bits $\{u'(0), \dots, u'(2039)\}$ is delivered to the encoder.

The 2040 bits $\{u'(0), \dots, u'(2039)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 10212 coded bits. The puncturing matrix P(6;2) as shown in table 4.29d is applied on the 10212 coded bits. This results in 4092 coded bits. A second stage of depuncturing as defined by D1 for PNB3(5,12) with ULMAP in table 4.29g is then applied. This operation results in a block of 4120 coded bits $\{b(0), \dots, b(4119)\}$ with an approximate coding rate of 0,495.

9.1.18.1.2 Interleaving

Same as clause 4.8.1.

Same as clause 4.9.

9.1.18.2 $\pi/4$ QPSK PNB3(5,12) Rate 5/8 burst carrying ULMAP

9.1.18.2.1 Channel coding

A 16-bit CRC is applied to the 2544 message bits d_0 to d_{2543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2543$. An 8-bit masking function is applied to the block of 2560 CRC-protected bits $\{u(0), \dots, u(2559)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2559)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2551$ and $u'(i + 2552) = u(i + 2552) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2560 bits $\{u'(0), \dots, u'(2559)\}$ is delivered to the encoder.

The 2560 bits $\{u'(0), \dots, u'(2559)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 12812 coded bits. The puncturing matrix P(34;10) as shown in table 4.29d is applied on the 12812 coded bits. This results in 4108 coded bits. A second stage of depuncturing as defined by D2 for PNB3(5,12) with ULMAP in table 4.29g is then applied. This operation results in a block of 4120 coded bits $\{b(0), \dots, b(4119)\}$ with an approximate coding rate of 0,621.

9.1.18.3.1 Channel coding

A 16-bit CRC is applied to the 3048 message bits d_0 to d_{3047} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3047$. An 8-bit masking function is applied to the block of 3064 CRC-protected bits $\{u(0), \dots, u(3063)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3063)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3055$ and $u'(i + 3056) = u(i + 3056) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3064 bits $\{u'(0), \dots, u'(3063)\}$ is delivered to the encoder.

The 3064 bits $\{u'(0), \dots, u'(3063)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 15332 coded bits. The puncturing matrix P(22;6) as shown in table 4.29d is applied on the 15332 coded bits. This results in 4096 coded bits. A second stage of depuncturing as defined by D3 for PNB3(5,12) with ULMAP in table 4.29g is then applied. This operation results in a block of 4120 coded bits $\{b(0), \dots, b(4119)\}$ with an approximate coding rate of 0,744.

9.1.18.4.1 Channel coding

A 16-bit CRC is applied to the 3400 message bits d_0 to d_{3399} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 3399$. An 8-bit masking function is applied to the block of 3416 CRC-protected bits $\{u(0), \dots, u(3415)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(3415)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 3407$ and $u'(i + 3408) = u(i + 3408) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 3416 bits $\{u'(0), \dots, u'(3415)\}$ is delivered to the encoder.

The 3416 bits $\{u'(0), \dots, u'(3415)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 17092 coded bits. The puncturing matrix P(38;10) as shown in table 4.29d is applied on the 17092 coded bits. This results in 4112 coded bits. A second stage of depuncturing as defined by D4 for PNB3(5,12) with ULMAP in table 4.29g is then applied. This operation results in a block of 4120 coded bits $\{b(0), \dots, b(4119)\}$ with an approximate coding rate of 0,829.

9.1.18.4.2 Interleaving

Same as clause 4.8.1.

9.1.18.4.3 Scrambling

Same as clause 4.9.

9.1.18.5 16APSK PNB3(5,12) Rate 2/3 burst carrying ULMAP

9.1.18.5.1 Channel coding

Two blocks of 2720 message bits, $\{d(0), \dots, d(2719)\}$ and $\{d'(0), \dots, d'(2719)\}$ are considered. A 16-bit CRC is applied to each 2720 message block as specified in clause 4.3. An 8-bit masking function is applied to each block of 2736 CRC-protected bits $\{u1(0), \dots, u1(2735)\}$ and $\{u2(0), \dots, u2(2735)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2735)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2727$ and $u'(i + 2728) = u(i + 2728) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant blocks of 2736 bits $\{u'(0), \dots, u'(2735)\}$ and $\{u''(0), \dots, u''(2735)\}$ is delivered to the encoder.

Each of the 2736 bit message block $\{u'(0), \dots, u'(2735)\}$ and $\{u''(0), \dots, u''(2735)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. During the encoding process, for the internal interleaving within the Turbo encoder the lookup table values as specified in table 4.29c is modified. For this particular case, the $n = 7$ column is replaced by 101,17,11,31,19,53,113,127,17,23,67,57,73,95,5,67,107,55,89,15,41,73,37,63,15,13,15,81,97,41,53,37. Encoding results in two blocks of 13692 coded bits. The puncturing matrix P(14;4) as shown in table 4.29d is applied on the 13692 coded bits. This results in 4116 coded bits. A second stage of depuncturing as defined by D5 for PNB3(5,12) with ULMAP in table 4.29g is then applied. This operation results in a two blocks of 4120 coded bits $\{b(0), \dots, b(4119)\}$ and $\{b'(0), \dots, b'(4119)\}$ with an approximate coding rate of 0,666. The 8240 bits from the two encoders are delivered to the 16APSK modulator.

9.1.18.5.2 Interleaving

The 8240 coded bits are serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(5,12) 16APSK carrying ULMAP, the block interleaver has 2060 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.18.5.3 Scrambling

Same as clause 4.9.

9.1.19 PNB3(10,3) burst

The information rate supported by the Turbo coded PNB3(10,3) depends on the modulation and the channel coding used. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.19.1 $\pi/4$ QPSK PNB3(10,3) burst Rate 1/2

9.1.19.1.1 Channel coding

A 16-bit CRC is applied to the 1024 message bits d_0 to d_{1023} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1023$. An 8-bit masking function is applied to the block of 1040 CRC-protected bits $\{u(0), \dots, u(1039)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1039)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1031$ and $u'(i + 1032) = u(i + 1032) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1040 bits $\{u'(0), \dots, u'(1039)\}$ is delivered to the encoder.

The 1040 bits $\{u'(0), \dots, u'(1039)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 5212 coded bits. The puncturing matrix P(6;2) as shown in table 4.29d is applied on the 5212 coded bits. This results in 2092 coded bits. A second stage of depuncturing as defined by D1 for PNB3(10,3) in table 4.29g is then applied. This operation results in a block of 2108 coded bits $\{b(0), \dots, b(2107)\}$ with an approximate coding rate of 0,4933.

A 16-bit CRC is applied to the 1552 message bits d_0 to d_{1551} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1551$. An 8-bit masking function is applied to the block of 1568 CRC-protected bits $\{u(0), \dots, u(1567)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1567)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1559$ and $u'(i + 1560) = u(i + 1560) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1568 bits $\{u'(0), \dots, u'(1567)\}$ is delivered to the encoder.

The 1568 bits $\{u'(0), \dots, u'(1567)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 7852 coded bits. The puncturing matrix P(22;6) as shown in table 4.29d is applied on the 7852 coded bits. This results in 2102 coded bits. A second stage of depuncturing as defined by D3 for PNB3(10,3) in table 4.29g is then applied. This operation results in a block of 2108 coded bits $\{b(0), \dots, b(2107)\}$ with an approximate coding rate of 0,743.

A 16-bit CRC is applied to the 1720 message bits d_0 to d_{1719} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1719$. An 8-bit masking function is applied to the block of 1736 CRC-protected bits $\{u(0), \dots, u(1735)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1735)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1727$ and $u'(i + 1728) = u(i + 1728) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1736 bits $\{u'(0), \dots, u'(1735)\}$ is delivered to the encoder.

The 1736 bits $\{u'(0), \dots, u'(1735)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.11. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 8692 coded bits. The puncturing matrix $P(38;10)$ as shown in table 4.29d is applied on the 8692 coded bits. This results in 2096 coded bits. A second stage of depuncturing as defined by D4 for PNB3(10,3) in table 4.29g is then applied. This operation results in a block of 2108 coded bits $\{b(0), \dots, b(2107)\}$ with an approximate coding rate of 0,823.

9.1.19.4.2 Interleaving

Same as clause 4.8.1.

9.1.19.4.3 Scrambling

Same as clause 4.9.

9.1.19.5 16APSK PNB3(10,3) Rate 2/3

9.1.19.5.1 Channel coding

A 16-bit CRC is applied to the 2936 message bits d_0 to d_{2935} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2935$. An 8-bit masking function is applied to the block of 2952 CRC-protected bits $\{u(0), \dots, u(2951)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2951)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2943$ and $u'(i + 2944) = u(i + 2944) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2952 bits $\{u'(0), \dots, u'(2951)\}$ is delivered to the encoder.

The 2952 bits $\{u'(0), \dots, u'(2951)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 14772 coded bits. The puncturing matrix $P(14;4)$ as shown in table 4.29d is applied on the 14772 coded bits. This results in 4440 coded bits. A second stage of puncturing as defined by P5 for PNB3(10,3) in table 4.29e is then applied. This operation results in a block of 4216 coded bits $\{b(0), \dots, b(4215)\}$ with an approximate coding rate of 0,7.

9.1.19.5.2 Interleaving

The 4216 coded bits are serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(10,3) 16APSK, the block interleaver has 1054 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.19.5.3 Scrambling

Same as clause 4.9.

9.1.20 PNB3(10,3) burst carrying ULMAP

The information rate supported by the Turbo coded PNB3(10,3) carrying ULMAP depends on the modulation and the channel coding used. Modulations include 16APSK, and $\pi/4$ QPSK. Approximate channel coding rates of 1/2, 5/8, 3/4, and 5/6 are supported for $\pi/4$ QPSK modulation and a channel coding rate of 2/3 is supported for 16APSK modulation.

9.1.20.1 $\pi/4$ QPSK PNB3(10,3) Rate 1/2 burst carrying ULMAP

9.1.20.1.1 Channel coding

A 16-bit CRC is applied to the 888 message bits d_0 to d_{887} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 887$. An 8-bit masking function is applied to the block of 904 CRC-protected bits $\{u(0), \dots, u(903)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(903)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 895$ and $u'(i + 896) = u(i + 896) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 904 bits $\{u'(0), \dots, u'(903)\}$ is delivered to the encoder.

The 904 bits $\{u'(0), \dots, u'(903)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 4532 coded bits. The puncturing matrix P(6;2) as shown in table 4.29d is applied on the 4532 coded bits. This results in 1820 coded bits. A second stage of depuncturing as defined by D1 for PNB3(10,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 1852 coded bits $\{b(0), \dots, b(1851)\}$ with an approximate coding rate of 0,488.

9.1.20.1.2 Interleaving

Same as clause 4.8.1.

9.1.20.1.3 Scrambling

Same as clause 4.9.

9.1.20.2 $\pi/4$ QPSK PNB3(10,3) Rate 5/8 burst carrying ULMAP

9.1.20.2.1 Channel coding

A 16-bit CRC is applied to the 1120 message bits d_0 to d_{1119} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1119$. An 8-bit masking function is applied to the block of 1136 CRC-protected bits $\{u(0), \dots, u(1135)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1135)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1127$ and $u'(i + 1128) = u(i + 1128) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1136 bits $\{u'(0), \dots, u'(1135)\}$ is delivered to the encoder.

The 1136 bits $\{u'(0), \dots, u'(1135)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 5692 coded bits. The puncturing matrix P(10;3) as shown in table 4.29d is applied on the 5692 coded bits. 4.29e is then applied. This operation results in a block of 1852 coded bits $\{b(0), \dots, b(1851)\}$ with an approximate coding rate of 0,613.

9.1.20.2.2 Interleaving

Same as clause 4.8.1.

9.1.20.2.3 Scrambling

Same as clause 4.9.

9.1.20.3 $\pi/4$ QPSK PNB3(10,3) Rate 3/4 burst carrying ULMAP

9.1.20.3.1 Channel coding

A 16-bit CRC is applied to the 1352 message bits d_0 to d_{1351} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1351$. An 8-bit masking function is applied to the block of 1368 CRC-protected bits $\{u(0), \dots, u(1367)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1367)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1359$ and $u'(i + 1360) = u(i + 1360) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1368 bits $\{u'(0), \dots, u'(1367)\}$ is delivered to the encoder.

The 1368 bits $\{u'(0), \dots, u'(1367)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 6852 coded bits. The puncturing matrix P(22;6) as shown in table 4.29d is applied on the 6852 coded bits. This results in 1836 coded bits. A second stage of depuncturing as defined by D3 for PNB3(10,3) with ULMAP in table 4.29g is then applied. This operation results in a block of 1852 coded bits $\{b(0), \dots, b(1851)\}$ with an approximate coding rate of 0,739.

9.1.20.3.2 Interleaving

Same as clause 4.8.1.

9.1.20.3.3 Scrambling

Same as clause 4.9.

9.1.20.4 $\pi/4$ QPSK PNB3(10,3) Rate 5/6 burst carrying ULMAP

9.1.20.4.1 Channel coding

A 16-bit CRC is applied to the 1496 message bits d_0 to d_{1495} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 1495$. An 8-bit masking function is applied to the block of 1512 CRC-protected bits $\{u(0), \dots, u(1511)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(1511)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 1503$ and $u'(i + 1504) = u(i + 1504) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 1512 bits $\{u'(0), \dots, u'(1511)\}$ is delivered to the encoder.

The 1512 bits $\{u'(0), \dots, u'(1511)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 7572 coded bits. The puncturing matrix P(30;8) as shown in table 4.29d is applied on the 7572 coded bits. This results in 1902 coded bits. A second stage of puncturing as defined by P7 for PNB3(10,3) with ULMAP in table 4.29e is then applied. This operation results in a block of 1852 coded bits $\{b(0), \dots, b(1851)\}$ with an approximate coding rate of 0,816.

9.1.20.4.2 Interleaving

Same as clause 4.8.1.

9.1.20.4.3 Scrambling

Same as clause 4.9.

9.1.20.5 16APSK PNB3(10,3) Rate 2/3 burst carrying ULMAP

9.1.20.5.1 Channel coding

A 16-bit CRC is applied to the 2544 message bits d_0 to d_{2543} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 2543$. An 8-bit masking function is applied to the block of 2560 CRC-protected bits $\{u(0), \dots, u(2559)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the last 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(2559)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 2551$ and $u'(i + 2552) = u(i + 2552) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 2560 bits $\{u'(0), \dots, u'(2559)\}$ is delivered to the encoder.

The 2560 bits $\{u'(0), \dots, u'(2559)\}$ are encoded via the rate 1/5 Turbo code. The code is defined by the generator polynomial specified in clause 4.11.1. The tail bits are punctured as shown in table 4.29a for Rate 1/2. Encoding results in 12812 coded bits. The puncturing matrix $P(14;4)$ as shown in table 4.29d is applied on the 12812 coded bits. This results in 3852 coded bits. A second stage of puncturing as defined by P_5 for PNB3(10,3) with ULMAP in table 4.29e is then applied. This operation results in a block of 3704 coded bits $\{b(0), \dots, b(3703)\}$ with an approximate coding rate of 0,691.

9.1.20.5.2 Interleaving

Same as clause 4.8.1. The 3704 coded bits are serially written into the interleaver column-wise (from the top to the bottom), and serially read out row-wise. For PNB3(10,3) 16APSK carrying ULMAP, the block interleaver has 926 rows and 4 columns. The bits $4i + 1$, $4i + 3$, $4i$ and $4i + 2$ of the output after interleaving determine the i^{th} 16APSK symbol.

9.1.20.5.3 Scrambling

Same as clause 4.9.

9.2 Packet Access Burst (PAB)

9.2.1 Channel coding

An 8-bit CRC is applied to 64 message bits d_0 to d_{63} as specified in clause 4.3, where $d(i) = d_i$, $i = 0, \dots, 63$. An 8-bit masking function is applied to the block of 72 CRC-protected bits $\{u(0), \dots, u(71)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-1 3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(71)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 63$ and $u'(i + 64) = u(i + 64) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 72 bits $\{u'(0), \dots, u'(71)\}$ is delivered to the encoder.

The 72 bits $\{u'(0), \dots, u'(71)\}$ are encoded via the rate 1/2 convolutional code. The code is defined by the generator polynomial specified in clause 4.4.2, where the constraint length $K = 7$ is used. Eight tail bits are used in order to accommodate $K = 9$ in the future for the possible enhancement. The encoding results in a block of 160 coded bits $\{b(0), \dots, b(159)\}$.

Puncturing is performed using mask $P(2;3)$ shown in table 4.6. Besides, one more bit in $\{b\}$ (with index 0) needs to be punctured. This turns out that 54 bits in $\{b\}$ with index $6k + 3$ ($k = 0, \dots, 26$), $6k + 4$ ($k = 0, \dots, 25$) and 0 are punctured. The result is a block of 106 coded bits $\{c(0), \dots, c(105)\}$. The coding rate after puncturing is approximately 3/4.

9.2.2 Interleaving

Intraburst interleaving is performed as described in clause 4.8.1.

9.2.3 Scrambling and multiplexing

No scrambling is performed.

9.2a Packet Access Burst3 (PAB3)

The message delivered to the encoder consists of 40 information bits $\{d_1(0), \dots, d_1(39)\}$.

9.2a.1 Channel coding

A 8-bit CRC is applied to the 40 message bits as specified in clause 4.3. An 8-bit masking function is applied to the block of 48 CRC-protected bits $\{u(0), \dots, u(47)\}$ in the following manner. The mask, $\{m(0), m(1), \dots, m(7)\}$, is the string RACH_SB_Mask broadcast in system information as specified in GMR-3G 44.008 [4]. Here $m(0)$ is the msb bit and $m(7)$ is the lsb bit of the mask. The 8-bit mask is applied to the 8 CRC bits of the message with an XOR operation to give us $\{u'(0), \dots, u'(47)\}$, where $u'(i) = u(i)$, $i = 0, \dots, 39$ and $u'(i + 40) = u(i + 40) \oplus m(i)$, $i = 0, \dots, 7$, where \oplus denotes modulo 2 addition (XOR). The resultant block of 48 bits $\{u'(0), \dots, u'(47)\}$ is delivered to the encoder.

The resultant block of 48 CRC-protected bits $\{u'(0), \dots, u'(47)\}$ is then encoded via the Rate 1/4 convolutional code as specified in clause 4.4.8. Convolutional encoding produces a block of 192 coded bits $\{b(0), \dots, b(191)\}$. Puncturing is performed using puncturing mask P(14;8) as defined in table 4.7b. This results in an output containing 112 coded bits. Additionally bits 60 and 120 are punctured to obtain a block containing 106 coded bits $\{c(0), \dots, c(105)\}$.

9.2a.2 Interleaving

Same as clause 4.8.1.

9.2a.3 Scrambling and multiplexing

Same as clause 4.9 in GMR-1 05.003 [3].

Annex A (normative): LDPC address parity bit accumulators

The Addresses of the Parity Bit Accumulators for the various LDPC codes are defined in tables A.1 to A.18 inclusive.
