Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Satellite Earth Stations and Systems (SES).

The present document is specifying the Satellite Radio Interface referenced as SRI Family G at ITU-R, in the frame of the modification of ITU-R Recommendation M.1457 [4]. This modification has been approved at SG8 meeting in November 2005.

The present document is part 3, sub-part 3 of a multi-part deliverable covering Satellite Earth Stations and Systems (SES); Satellite Component of UMTS/IMT-2000; G-family enhancements, as identified below:

Part 1: "Physical channels and mapping of transport channels into physical channels";

Part 2: "Multiplexing and channel coding";

Part 3: "Spreading and modulation";

Sub-part 1: "G-family (S-UMTS-G 25.213)";

Sub-part 2: "A-family (S-UMTS-A 25.213)";

Sub-part 3: "G-family enhancements (S-UMTS-G enhanced 25.213)";

Part 4: "Physical layer procedures";

Part 5: "UE Radio Transmission and Reception";

Part 6: "Ground stations and space segment radio transmission and reception".

Introduction

S-UMTS stands for the Satellite component of the Universal Mobile Telecommunication System. S-UMTS systems will complement the Terrestrial UMTS (T-UMTS) and inter-work with other IMT-2000 family members through the UMTS core network. S-UMTS will be used to deliver 3rd generation Mobile Satellite Services (MSS) utilizing either low (LEO) or medium (MEO) earth orbiting, or geostationary (GEO) satellite(s). S-UMTS systems are based on terrestrial 3GPP specifications and will support access to GSM/UMTS core networks.

NOTE 1: The term T-UMTS will be used in the present document to further differentiate the Terrestrial UMTS component.

Due to the differences between terrestrial and satellite channel characteristics, some modifications to the terrestrial UMTS (T-UMTS) standards are necessary. Some specifications are directly applicable, whereas others are applicable with modifications. Similarly, some T-UMTS specifications do not apply, whilst some S-UMTS specifications have no corresponding T-UMTS specification.

Since S-UMTS is derived from T-UMTS, the organization of the S-UMTS specifications closely follows the original 3rd Generation Partnership Project (3GPP) structure. The S-UMTS numbers have been designed to correspond to the 3GPP terrestrial UMTS numbering system. All S-UMTS specifications are allocated a unique S-UMTS number as follows:

S-UMTS-n xx.yyy

Where:

- The numbers xx and yyy correspond to the 3GPP numbering scheme.

- n (n = A, B, C, etc.) denotes the family of S-UMTS specifications.

An S-UMTS system is defined by the combination of a family of S-UMTS specifications and 3GPP specifications, as follows:

- If an S-UMTS specification exists it takes precedence over the corresponding 3GPP specification (if any). This precedence rule applies to any references in the corresponding 3GPP specifications.

NOTE 2: Any references to 3GPP specifications within the S-UMTS specifications are not subject to this precedence rule.

EXAMPLE: An S-UMTS specification may contain specific references to the corresponding 3GPP specification.

- If an S-UMTS specification does not exist, the corresponding 3GPP specification may or may not apply. The exact applicability of the complete list of 3GPP specifications shall be defined at a later stage.

The present document is part of the S-UMT sub-part 3 specifications. Sub-part 3 specifications are identified in the title and can also be identified by the specification number:

- Sub-part 1 specifications have a S-UMTS-G prefix in the title and a sub-part number of "1"
  (TS 101 851-x-1).

- Sub-part 2 specifications have a S-UMTS-A prefix in the title and a sub-part number of "2"
  (TS 101 851-x-2).

- Sub-part 3 specifications have a S-UMTS-G enhanced prefix in the title and a sub-part number of "3"
  (TS 101 851-x-3).

The sub-part 1 specifications introduce the WCDMA satellite radio interface (ITU-R G-family) specifications for the third generation (3G) wireless communication systems. It is also based on the WCDMA UTRA FDD radio interface already standardized in 3GPP. Mobile satellite systems intending to use this interface will address user equipment fully compatible with 3GPP UTRA FDD WCDMA, with adaptation for agility to the Mobile Satellite Service (MSS) frequency band.

The sub-part 2 specifications introduce the SW-CDMA satellite radio interface (ITU-R A-family) specifications for third generation (3G) wireless communication systems. SW-CDMA is based on the adaptation to the satellite environment of terrestrial WCDMA. The intention is to reuse the same core network and reuse the radio interface specifications for the Is and Cu interface. Only the Uu interface is adapted to the satellite environment. SW-CDMA operates in FDD mode with RF channel bandwidth of either 2,350 MHz or 4,700 MHz for each transmission direction.

The sub-part 3 specifications introduce the WCDMA satellite radio interface enhancement (G enhance-family). It considers G-family as radio interface basis, adding as option selected enhancing features from ITU-R A and/or C-family in order to optimize the radio interface over satellite. It is based on the results of the TR 102 278 [i.1] identifying a way to achieve harmonization between A, C and G-family satellite radio interfaces for IMT-2000 in ITU-R.
The G-family enhancements made of A, C and G features are described in annex B.

- The sub-parts 1 and 2 will be withdrawn if the A and C family will be removed from the satellite radio interface list of IMT-2000 in ITU-R Recommendation M.1850 [i.2] and then, the sub-part 3 will be revised.

1 Scope

The present document describes spreading and modulation for the Physical Layer for family G enhanced of the satellite component of UMTS (S-UMTS-G enhanced).

It is based on the FDD mode of UTRA defined by TS 101 851-1-3 [1], TS 101 851-2-3 [2], TS 101 851-4-3 [3] and adapted for operation over satellite transponders.

Furthermore, it specifies enhancing features optimizing the basic G family radio interface performances over satellite and new functions.

2 References

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the reference document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at http://docbox.etsi.org/Reference.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

3   Symbols and abbreviations

3.1   Symbols

For the purposes of the present document, the following symbols apply:

δ	The Kronecker delta function
$C_{ch,SF,n}$	n:th channelization code with spreading factor SF
$C_{pre,n,s}$	PRACH preamble code for n:th preamble scrambling code and signature s
$C_{sig,s}$	PRACH/PCPCH signature code for signature s
$S_{dpch,n}$	n:th DPCCH/DPDCH uplink scrambling code
$S_{r-pre,n}$	n:th PRACH preamble scrambling code
$S_{r-msg,n}$	n:th PRACH message scrambling code
$S_{dl,n}$	DL scrambling code
C_{psc}	PSC code
$C_{ssc,n}$	n:th SSC code

3.2   Abbreviations

For the purposes of the present document, the following abbreviations apply:

AI	Acquisition Indicator
AICH	Acquisition Indicator Channel
BPSK	Binary Phase Shift Keying
CCPCH	Common Control Physical CHannel
CLPC	Closed Loop Power Control
CPICH	Common PIlot CHannel
DCH	Dedicated CHannel
DPCCH	Dedicated Physical Control CHannel
DPCH	Dedicated Physical CHannel
DPDCH	Dedicated Physical Data CHannel
DTX	Discontinuous Transmission
FBI	FeedBack Indicator

FDD	Frequency Division Duplex
GEO	Geostationary Earth Orbit
HPPICH	High Penetration Paging Indicator CHannel
ID	Identity
LEO	Low Earth Orbit
Mcps	Mega chip per second
MEO	Medium Earth Orbit
MICH	MBMS Indication Channel
ML	Maximum Likelihood
MSS	Mobile Satellite Services
OLPC	Open Loop Power Control
OVSF	Orthogonal Variable Spreading Factor (codes)
PICH	Page Indication CHannel
PRACH	Physical Random Access CHannel
PSC	Primary Synchronization Code
QPSK	Quaternary Phase Shift Keying
RACH	Random Access CHannel
RF	Radio Frequency
S-CCPCH	Secondary Common Control Physical CHannel
SCH	Synchronization CHannel
SF	Spreading Factor
SIR	Signal to Interference power Ratio
SSC	Secondary Synchronization Code
SSDT	Site Selection Diversity Transmission
S-UMTS	Satellite Universal Mobile Telecommunications System
SW-CDMA	Satellite Wideband Code Division Multiple Access
TPC	Transmit Power Control
TrCH	Transport CHannel
T-UMTS	Terrestrial Universal Mobile Telecommunications System
USRAN	UMTS Satellite Radio Access Network
UTRA	UMTS Terrestrial Radio Access
UW	Unique Word
WCDMA	Wideband Code Division Multiple Access

4   Uplink spreading and modulation

4.1   Overview

Spreading is applied to the physical channels. It consists of two operations. The first is the channelization operation, which transforms every data symbol into a number of chips, thus increasing the bandwidth of the signal. The number of chips per data symbol is called the Spreading Factor (SF). The second operation is the scrambling operation, where a scrambling code is applied to the spread signal.

With the channelization, data symbols on so-called I- and Q-branches are independently multiplied with an OVSF code. With the scrambling operation, the resultant signals on the I- and Q-branches are further multiplied by complex-valued scrambling code, where I and Q denote real and imaginary parts, respectively.

4.2   Spreading

4.2.1   DPCCH/DPDCH

Figure 1 illustrates the principle of the uplink spreading of DPCCH and DPDCHs. The binary DPCCH and DPDCHs to be spread are represented by real-valued sequences, i.e. the binary value "0" is mapped to the real value +1, and the binary value "1" is mapped to the real value -1. The DPCCH is spread to the chip rate by the channelization code c_c. The n:th DPDCH called DPDCH$_n$ is spread to the chip rate by the channelization code $c_{d,n}$. One DPCCH, up to six parallel DPDCHs, i.e. $1 \leq n \leq 6$.
Figure 1: Spreading for uplink DPCCH and DPDCHs

After channelization, the real-valued spread signals are weighted by gain factors, β_c for DPCCH, and β_d for all DPDCHs.

The β_c and β_d values are signalled by higher layers or calculated as described in TS 101 851-4-3 [3]. At every instant in time, at least one of the values β_c and β_d has the amplitude 1,0. The β_c and β_d values are quantized into 4 bit words. The quantization steps are given in table 1.

Table 1: The quantization of the gain parameters

Signalling values for β_c and β_d	Quantized amplitude ratios β_c and β_d
15	1,0
14	14/15
13	13/15
12	12/15
11	11/15
10	10/15
9	9/15
8	8/15
7	7/15
6	6/15
5	5/15
4	4/15
3	3/15
2	2/15
1	1/15
0	Switch off

After the weighting, the stream of real-valued chips on the I- and Q-branches are then summed and treated as a complex-valued stream of chips. This complex-valued signal is then scrambled by the complex-valued scrambling code $S_{dpch,n}$. The scrambling code is applied aligned with the radio frames, i.e. the first scrambling chip corresponds to the beginning of a radio frame.

4.2.2   PRACH

4.2.2.1   PRACH preamble part

The PRACH preamble part consists of a complex-valued code, described in clause 4.3.3.

4.2.2.2   PRACH message part

Figure 2 illustrates the principle of the spreading and scrambling of the PRACH message part, consisting of data and control parts. The binary control and data parts to be spread are represented by real-valued sequences, i.e. the binary value "0" is mapped to the real value +1, while the binary value "1" is mapped to the real value -1. The control part is spread to the chip rate by the channelization code c_c, while the data part is spread to the chip rate by the channelization code c_d.

Figure 2: Spreading of PRACH message part

After channelization, the real-valued spread signals are weighted by gain factors, β_c for the control part and β_d for the data part. At every instant in time, at least one of the values β_c and β_d has the amplitude 1,0. The β-values are quantized into 4 bit words. The quantization steps are given in clause 4.2.1.

After the weighting, the stream of real-valued chips on the I- and Q-branches is treated as a complex-valued stream of chips. This complex-valued signal is then scrambled by the complex-valued scrambling code $S_{r\text{-}msg,n}$. The 10 ms scrambling code is applied aligned with the 10 ms message part radio frames, i.e. the first scrambling chip corresponds to the beginning of a message part radio frame.

4.3   Code generation and allocation

4.3.1   Channelization codes

4.3.1.1   Code definition

The channelization codes of figure 1 are Orthogonal Variable Spreading Factor (OVSF) codes that preserve the orthogonality between a user's different physical channels. The OVSF codes can be defined using the code tree of figure 3.
Figure 3: Code-tree for generation of Orthogonal Variable Spreading Factor (OVSF) codes

In figure 3, the channelization codes are uniquely described as $C_{ch,SF,k}$, where SF is the spreading factor of the code and k is the code number, $0 \le k \le SF- 1$.

Each level in the code tree defines channelization codes of length SF, corresponding to a spreading factor of SF in figure 3.

The generation method for the channelization code is defined as:

$$C_{ch,1,0} = 1,$$

$$\begin{bmatrix} C_{ch,2,0} \\ C_{ch,2,1} \end{bmatrix} = \begin{bmatrix} C_{ch,1,0} & C_{ch,1,0} \\ C_{ch,1,0} & -C_{ch,1,0} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

$$
\begin{bmatrix}
C_{ch,2^{(n+1)},0} \\
C_{ch,2^{(n+1)},1} \\
C_{ch,2^{(n+1)},2} \\
C_{ch,2^{(n+1)},3} \\
\vdots \\
C_{ch,2^{(n+1)},2^{(n+1)}-2} \\
C_{ch,2^{(n+1)},2^{(n+1)}-1}
\end{bmatrix}
=
\begin{bmatrix}
C_{ch,2^n,0} & C_{ch,2^n,0} \\
C_{ch,2^n,0} & -C_{ch,2^n,0} \\
C_{ch,2^n,1} & C_{ch,2^n,1} \\
C_{ch,2^n,1} & -C_{ch,2^n,1} \\
\vdots & \vdots \\
C_{ch,2^n,2^n-1} & C_{ch,2^n,2^n-1} \\
C_{ch,2^n,2^n-1} & -C_{ch,2^n,2^n-1}
\end{bmatrix}
$$

The leftmost value in each channelization code word corresponds to the chip transmitted first in time.

4.3.1.2 Code allocation for DPCCH/DPDCH

For the DPCCH and DPDCHs the following applies:

- The DPCCH is always spread by code $c_c = C_{ch,256,0}$.

- When only one DPDCH is to be transmitted, $DPDCH_1$ is spread by code $c_{d,1} = C_{ch,SF,k}$ where SF is the spreading factor of $DPDCH_1$ and k = SF / 4.

- When more than one DPDCH is to be transmitted, all DPDCHs have spreading factors equal to 4. $DPDCH_n$ is spread by the code $c_{d,n} = C_{ch,4,k}$, where $k = 1$ if $n \in \{1, 2\}$, $k = 3$ if $n \in \{3, 4\}$, and $k = 2$ if $n \in \{5, 6\}$.

If a power control preamble is used to initialize a DCH, the channelization code for the DPCCH during the power control preamble shall be the same as that to be used afterwards.

4.3.1.3 Code allocation for PRACH message part

The preamble signature s, $0 \le s \le 15$, points to one of the 16 nodes in the code-tree that corresponds to channelization codes of length 16. The sub-tree below the specified node is used for spreading of the message part. The control part is spread with the channelization code c_c (as shown in clause 4.2.2.2) of spreading factor 256 in the lowest branch of the sub-tree, i.e. $c_c = C_{ch,256,m}$ where m = 16 × s + 15. The data part uses any of the channelization codes from spreading factor 32 to 256 in the upper-most branch of the sub-tree. To be exact, the data part is spread by channelization code $c_d = C_{ch,SF,m}$ and SF is the spreading factor used for the data part and m = SF × s / 16.

4.3.2 Scrambling codes

4.3.2.1 General

All uplink physical channels are subjected to scrambling with a complex-valued scrambling code. The DPCCH/DPDCH may be scrambled by either long or short scrambling codes, defined in clause 4.3.2.4. The PRACH message part is scrambled with a long scrambling code, defined in clause 4.3.2.5.

There are 2^{24} long and 2^{24} short uplink scrambling codes. Uplink scrambling codes are assigned by higher layers.

The long scrambling code is built from constituent long sequences defined in clause 4.3.2.2, while the constituent short sequences used to build the short scrambling code are defined in clause 4.3.2.3.

4.3.2.2 Long scrambling sequence

The long scrambling sequences $c_{long,1,n}$ and $c_{long,2,n}$ are constructed from position wise modulo 2 sum of 38 400 chips segments of two binary m-sequences generated by means of two generator polynomials of degree 25. Let x, and y be the two m-sequences respectively. The x sequence is constructed using the primitive (over GF(2)) polynomial $X^{25} + X^3 + 1$. The y sequence is constructed using the polynomial $X^{25} + X^3 + X^2 + X + 1$. The resulting sequences thus constitute segments of a set of Gold sequences.

The sequence $c_{long,2,n}$ is a 16 777 232 chips shifted version of the sequence $c_{long,1,n}$.

Let $n_{23} \ldots n_0$ be the 24 bit binary representation of the scrambling sequence number n with n_0 being the least significant bit. The x sequence depends on the chosen scrambling sequence number n and is denoted x_n, in the sequel. Furthermore, let $x_n(i)$ and $y(i)$ denote the i:th symbol of the sequence x_n and y, respectively.

The m-sequences x_n and y are constructed as:

Initial conditions:

- $x_n(0) = n_0 , x_n(1) = n_1 , \ldots = x_n(22) = n_{22} , x_n(23) = n_{23}, x_n(24) = 1.$

- $y(0) = y(1) = \ldots = y(23) = y(24) = 1.$

Recursive definition of subsequent symbols:

- $x_n(i + 25) = x_n(i + 3) + x_n(i) \text{ modulo } 2, i = 0,\ldots, 2^{25} - 27.$

- $y(i + 25) = y(i + 3) + y(i + 2) + y(i + 1) + y(i) \text{ modulo } 2, i = 0,\ldots, 2^{25} - 27.$

Define the binary Gold sequence z_n by:

- $z_n(i) = x_n(i) + y(i) \text{ modulo } 2, i = 0, 1, 2, \ldots, 2^{25} - 2.$

The real valued Gold sequence Z_n is defined by:

$$Z_n(i) = \begin{cases} +1 & if \ z_n(i) = 0 \\ -1 & if \ z_n(i) = 1 \end{cases} \quad for \ \ i = 0,1,\ldots,2^{25} - 2.$$

Now, the real-valued long scrambling sequences $c_{long,1,n}$ and $c_{long,2,n}$ are defined as follows:

$$c_{long,1,n}(i) = Z_n(i), i = 0, 1, 2, \ldots, 2^{25} - 2; \text{ and}$$

$$c_{long,2,n}(i) = Z_n((i + 16\ 777\ 232) \text{ modulo } (2^{25} - 1)), i = 0, 1, 2, \ldots, 2^{25} - 2.$$

Finally, the complex-valued long scrambling sequence $C_{long, n}$, is defined as:

$$C_{long,n}(i) = c_{long,1,n}(i)\left(1 + j(-1)^i c_{long,2,n}\left(2\lfloor i / 2 \rfloor\right)\right)$$

where $i = 0, 1, \ldots, 2^{25} - 2$ and $\lfloor \ \rfloor$ denotes rounding to nearest lower integer.

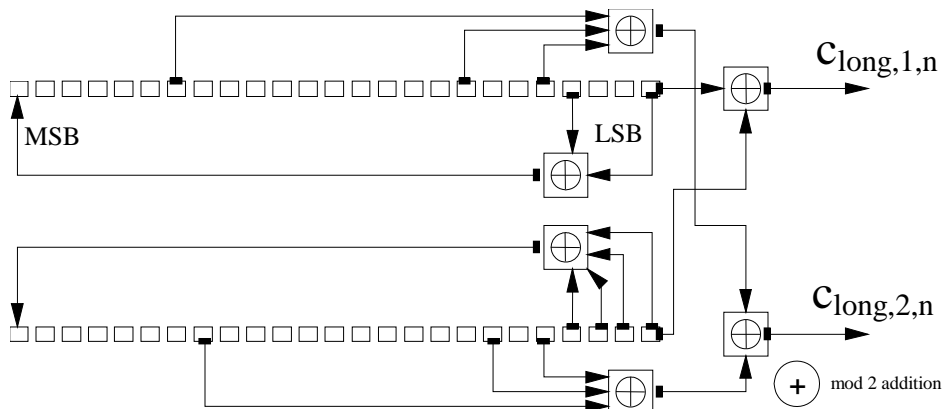

Figure 4: Configuration of uplink scrambling sequence generator

4.3.2.3   Short scrambling sequence

The short scrambling sequences $c_{short,1,n}(i)$ and $c_{short,2,n}(i)$ are defined from a sequence from the family of periodically extended S(2) codes.

Let $n_{23}n_{22}...n_0$ be the 24 bit binary representation of the code number n.

The n:th quaternary S(2) sequence $z_n(i)$, $0 \le n \le 16\ 777\ 215$, is obtained by modulo 4 addition of three sequences, a quaternary sequence $a(i)$ and two binary sequences $b(i)$ and $d(i)$, where the initial loading of the three sequences is determined from the code number n. The sequence $z_n(i)$ of length 255 is generated according to the following relation:

- $z_n(i) = a(i) + 2b(i) + 2d(i)$ modulo 4, $i = 0, 1, ..., 254$;

where the quaternary sequence $a(i)$ is generated recursively by the polynomial
$g_0(x) = x^8 + x^5 + 3x^3 + x^2 + 2x + 1$ as:

- $a(0) = 2n_0 + 1$ modulo 4;

- $a(i) = 2n_i$ modulo 4, $i = 1, 2, ..., 7$;

- $a(i) = 3a(i - 3) + a(i - 5) + 3a(i - 6) + 2a(i - 7) + 3a(i - 8)$ modulo 4, $i = 8, 9, ..., 254$;

and the binary sequence $b(i)$ is generated recursively by the polynomial
$g_1(x) = x^8 + x^7 + x^5 + x + 1$ as:

$b(i) = n_{8+i}$ modulo 2, $i = 0, 1, ..., 7$;

$b(i) = b(i - 1) + b(i - 3) + b(i - 7) + b(i - 8)$ modulo 2, $i = 8, 9, ..., 254$;

and the binary sequence $d(i)$ is generated recursively by the polynomial
$g_2(x) = x^8 + x^7 + x^5 + x^4 + 1$ as:

$d(i) = n_{16+i}$ modulo 2, $i = 0, 1, ..., 7$;

$d(i) = d(i - 1) + d(i - 3) + d(i - 4) + d(i - 8)$ modulo 2, $i = 8, 9, ..., 254$.

The sequence $z_n(i)$ is extended to length 256 chips by setting $z_n(255) = z_n(0)$.

The mapping from $z_n(i)$ to the real-valued binary sequences $c_{short,1,n}(i)$ and $c_{short,2,n}(i)$, , $i = 0, 1, ..., 255$ is defined in table 2.

Table 2: Mapping from $z_n(i)$ to $c_{short,1,n}(i)$ and $c_{short,2,n}(i)$, $i = 0, 1, ..., 255$

$z_n(i)$	$c_{short,1,n}(i)$	$c_{short,2,n}(i)$
0	+1	+1
1	-1	+1
2	-1	-1
3	+1	-1

Finally, the complex-valued short scrambling sequence $C_{short,\ n}$, is defined as:

$$C_{short,n}(i) = c_{short,1,n}(i \bmod 256)\left(1 + j(-1)^i c_{short,2,n}\left(2\lfloor (i \bmod 256)/2 \rfloor\right)\right)$$

where $i = 0, 1, 2, ...$ and $\lfloor \rfloor$ denotes rounding to nearest lower integer.

An implementation of the short scrambling sequence generator for the 255 chips sequence to be extended by one chip is shown in figure 5.
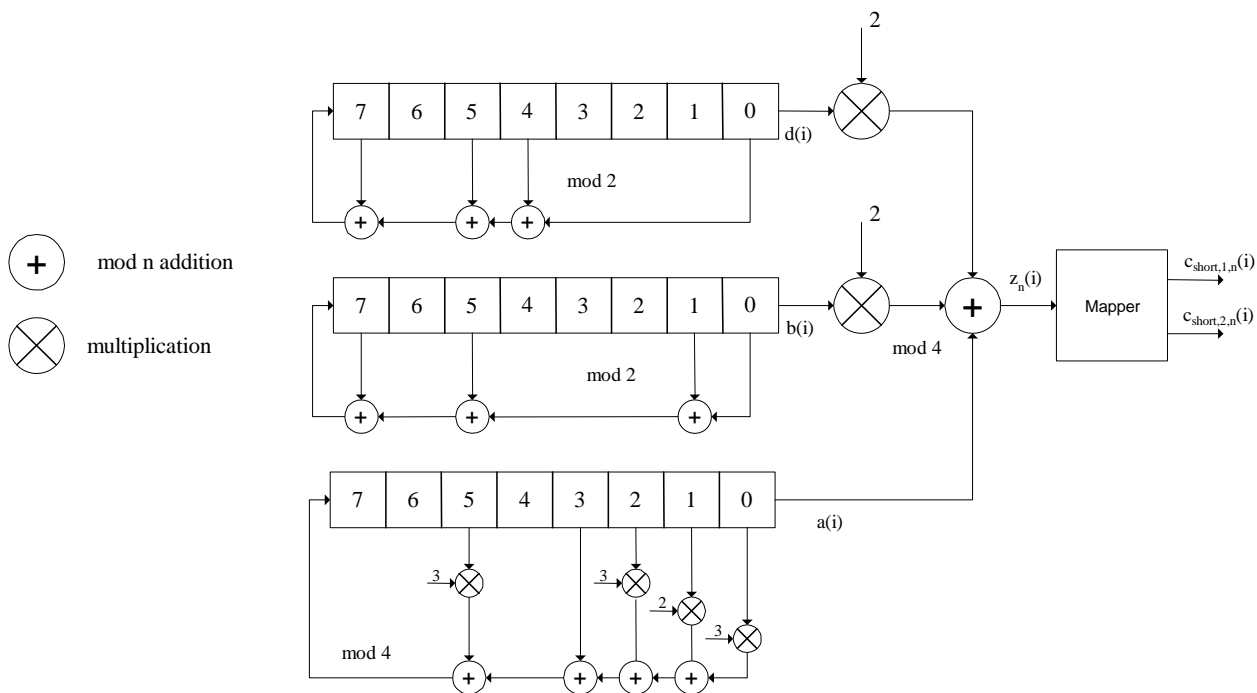

Figure 5: Uplink short scrambling sequence generator for 255 chips sequence

4.3.2.4   DPCCH/DPDCH scrambling code

The code used for scrambling of the uplink DPCCH/DPDCH may be of either long or short type. When the scrambling code is formed, different constituent codes are used for the long and short type as defined below.

The n:th uplink scrambling code for DPCCH/DPDCH, denoted $S_{dpch,n}$, is defined as:

$$S_{dpch,n}(i) = C_{long,n}(i), i = 0, 1, \ldots, 38\ 399, \text{ when using long scrambling codes,}$$

where the lowest index corresponds to the chip transmitted first in time and $C_{long,n}$ is defined in clause 4.3.2.2.

The n:th uplink scrambling code for DPCCH/DPDCH, denoted $S_{dpch,n}$, is defined as:

$$S_{dpch,n}(i) = C_{short,n}(i), i = 0, 1, \ldots, 38\ 399, \text{ when using short scrambling codes,}$$

where the lowest index corresponds to the chip transmitted first in time and $C_{short,n}$ is defined in clause 4.3.2.3.

4.3.2.5   PRACH message part scrambling code

The scrambling code used for the PRACH message part is 10 ms long, and there are 8 192 different PRACH scrambling codes defined.

The n:th PRACH message part scrambling code, denoted $S_{r-msg,n}$, where $n = 0, 1, \ldots, 8\ 191$, is based on the long scrambling sequence and is defined as:

$$S_{r-msg,n}(i) = C_{long,n}(i + 4\ 096), i = 0, 1, \ldots, 38\ 399,$$

where the lowest index corresponds to the chip transmitted first in time and $C_{long,n}$ is defined in clause 4.3.2.2.

The message part scrambling code has a one-to-one correspondence to the scrambling code used for the preamble part. For one PRACH, the same code number is used for both scrambling codes, i.e. if the PRACH preamble scrambling code used is $S_{r-pre,m}$ then the PRACH message part scrambling code is $S_{r-msg,m}$, where the number m is the same for both codes.

4.3.3   PRACH preamble codes

4.3.3.1   Preamble code construction

The random access preamble code $C_{pre,n,}$ is a complex valued sequence. It is built from a preamble scrambling code $S_{r-pre,n}$ and a preamble signature $C_{sig,s}$ as follows:

-        $C_{pre,n,s}(k) = S_{r-pre,n}(k) \times C_{sig,s}(k) \times e^{j(\frac{\pi}{4}+\frac{\pi}{2}k)}$, k = 0, 1, 2, 3, …, 4 095,

where k = 0 corresponds to the chip transmitted first in time and $S_{r-pre,n}$ and $C_{sig,s}$ are defined in clauses 4.3.3.2 and 4.3.3.3 respectively.

In optional mode C, the following is applied :the random access preamble code is of length N_{sp}*4 096 chips and consists of N_{sp} sub-preamble codes, $C_{pre,n,s,0}$, $C_{pre,n,s,1}$, …, $C_{pre,n,s,Nsp-1}$. The sub-preamble code Cpre,n,s,i is a complex valued sequence. It is built from a preamble scrambling code $S_{r-pre,n}$ and a preamble signature $C_{sig,s}$ as follows:

when N_{sp} is set to 1, then

-        $C_{pre,n,s,0}(k) = S_{r-pre,n}(k) \times C_{sig,s}(k) \times e^{j(\frac{\pi}{4}+\frac{\pi}{2}k)}$, k = 0, 1, 2, 3, …, 4 095,

when N_{sp} exceeds 1, then

-        $C_{pre,n,s,i}(k) = S_{r-pre,n}(k) \times C_{sig,s}(k) \times e^{j(\frac{\pi}{4}+\frac{\pi}{2}k)}$, k = 0, 1, 2, 3, …, 4 095, i = 0, 1, …, N_{sp}-2

-        $C_{pre,n,s,Nsp-1}(k) = S_{r-pre,n}(k) \times C_{sig,s}(k) \times e^{-j(\frac{\pi}{4}+\frac{\pi}{2}k)}$, k = 0, 1, 2, 3, …, 4 095;

where k = 0 corresponds to the chip transmitted first in time and $S_{r-pre,n}$ and $C_{sig,s}$ are defined in clauses 4.3.3.2 and 4.3.3.3 respectively.

4.3.3.2   Preamble scrambling code

The scrambling code for the PRACH preamble part is constructed from the long scrambling sequences. There are 8 192 PRACH preamble scrambling codes in total.

The n:th preamble scrambling code, n = 0, 1, …, 8 191, is defined as:

-        $S_{r-pre,n}(i) = c_{long,1,n}(i)$, i = 0, 1, …, 4 095;

where the sequence $c_{long,1,n}$ is defined in clause 4.3.2.2.

The 8 192 PRACH preamble scrambling codes are divided into 512 groups with 16 codes in each group. There is a one-to-one correspondence between the group of PRACH preamble scrambling codes in a cell and the primary scrambling code used in the downlink of the cell. The k:th PRACH preamble scrambling code within the cell with downlink primary scrambling code m, k = 0, 1, 2, …, 15 and m = 0, 1, 2, …, 511, is $S_{r-pre,n}(i)$ as defined above with $n = 16 \times m + k$.

In optional mode C, the following is applied: when sub-access frames are used for the PRACH, the k:th PRACH preamble scrambling code where k is an even number is used for the preamble transmitted at the even sub-access frame. The k:th PRACH preamble scrambling code where k is an odd number is used for the preamble transmitted at the odd sub-access frame.

4.3.3.3   Preamble signature

The preamble signature corresponding to a signature s consists of 256 repetitions of a length 16 signature $P_s(n)$, n = 0…15. This is defined as follows:

-    $C_{sig,s}(i) = P_s(i$ modulo 16$)$, $i = 0, 1, …, 4$ 095.

The signature $P_s(n)$ is from the set of 16 Hadamard codes of length 16. These are listed in table 3.

Table 3: Preamble signatures

Preamble signature	Value of *n*															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
$P_0(n)$	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
$P_1(n)$	1	-1	1	-1	1	-1	1	-1	1	-1	1	-1	1	-1	1	-1
$P_2(n)$	1	1	-1	-1	1	1	-1	-1	1	1	-1	-1	1	1	-1	-1
$P_3(n)$	1	-1	-1	1	1	-1	-1	1	1	-1	-1	1	1	-1	-1	1
$P_4(n)$	1	1	1	1	-1	-1	-1	-1	1	1	1	1	-1	-1	-1	-1
$P_5(n)$	1	-1	1	-1	-1	1	-1	1	1	-1	1	-1	-1	1	-1	1
$P_6(n)$	1	1	-1	-1	-1	-1	1	1	1	1	-1	-1	-1	-1	1	1
$P_7(n)$	1	-1	-1	1	-1	1	1	-1	1	-1	-1	1	-1	1	1	-1
$P_8(n)$	1	1	1	1	1	1	1	1	-1	-1	-1	-1	-1	-1	-1	-1
$P_9(n)$	1	-1	1	-1	1	-1	1	-1	-1	1	-1	1	-1	1	-1	1
$P_{10}(n)$	1	1	-1	-1	1	1	-1	-1	-1	-1	1	1	-1	-1	1	1
$P_{11}(n)$	1	-1	-1	1	1	-1	-1	1	-1	1	1	-1	-1	1	1	-1
$P_{12}(n)$	1	1	1	1	-1	-1	-1	-1	-1	-1	-1	-1	1	1	1	1
$P_{13}(n)$	1	-1	1	-1	-1	1	-1	1	-1	1	-1	1	1	-1	1	-1
$P_{14}(n)$	1	1	-1	-1	-1	-1	1	1	-1	-1	1	1	1	1	-1	-1
$P_{15}(n)$	1	-1	-1	1	-1	1	1	-1	-1	1	1	-1	1	-1	-1	1

4.4   Modulation

4.4.1   Modulating chip rate

The modulating chip rate is 3,84 Mcps.

4.4.2   Modulation

Modulation of the complex-valued chip sequence generated by the spreading process is shown in figure 6.

Figure 6: Uplink modulation

The pulse-shaping characteristics are described in TS 101 851-2-3 [2].

5   Downlink spreading and modulation

5.1   Spreading

Figure 7 illustrates the spreading operation for the physical channel except SCH. The downlink physical channels using QPSK are P-CCPCH, S-CCPCH, CPICH, AICH, PICH, MICH and downlink DPCH. The downlink physical channel using either QPSK. The non-spread downlink physical channels, except SCH, AICH, consist of a sequence of 3-valued digits taking the values 0, 1 and "DTX". Note that "DTX" is only applicable to those downlink physical channels that support DTX transmission. In case of QPSK, these digits are mapped to real-valued symbols as follows: the binary value "0" is mapped to the real value +1, the binary value "1" is mapped to the real value -1 and "DTX" is mapped to the real value 0. For the indicator channels using signatures (AICH), the real-valued symbols depend on the exact combination of the indicators to be transmitted.

In case of QPSK, each pair of two consecutive real-valued symbols is first serial-to-parallel converted and mapped to an I and Q branch. The definition of the modulation mapper is such that even and odd numbered symbols are mapped to the I and Q branch respectively. In case of QPSK, for all channels except the indicator channels using signatures, symbol number zero is defined as the first symbol in each frame. For the indicator channels using signatures, symbol number zero is defined as the first symbol in each access slot. The I and Q branches are then both spread to the chip rate by the same real-valued channelization code $C_{ch,SF,m}$. The channelization code sequence shall be aligned in time with the symbol boundary. The sequences of real-valued chips on the I and Q branch are then treated as a single complex-valued sequence of chips. This sequence of chips is scrambled (complex chip-wise multiplication) by a complex-valued scrambling code $S_{dl,n}$.

**Figure 7: Spreading for all downlink physical channels except SCH**

Figure 8 illustrates how different downlink channels are combined. Each complex-valued spread channel, corresponding to point S in figure 7, is separately weighted by a weight factor G_i. The complex-valued P-SCH and S-SCH, are separately weighted by weight factors G_p and G_s. All downlink physical channels are then combined using complex addition.
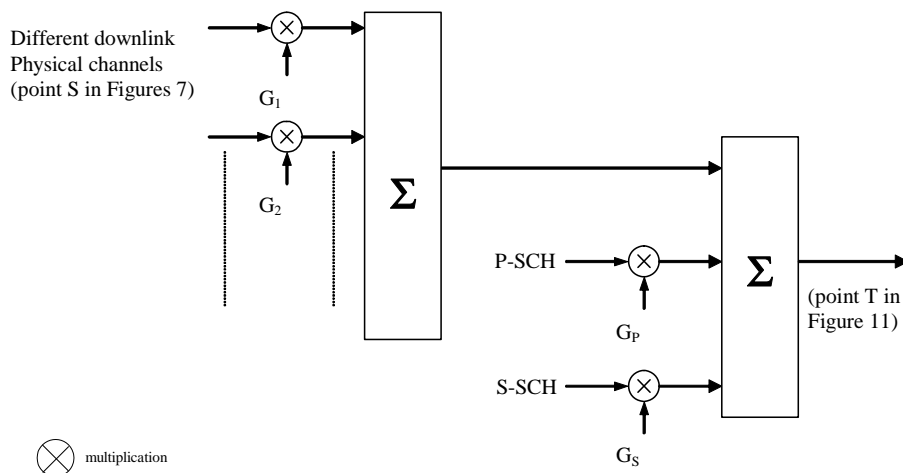

Figure 8: Combining of downlink physical channels

5.2   Code generation and allocation

5.2.1   Channelization codes

The channelization codes of figure 7 are the same codes as used in the uplink, namely Orthogonal Variable Spreading Factor (OVSF) codes that preserve the orthogonality between downlink channels of different rates and spreading factors. The OVSF codes are defined in figure 3 in clause 4.3.1.

The channelization code for the Primary CPICH is fixed to $C_{ch,256,0}$. The channelization codes for all other physical channels are assigned by USRAN.

With the spreading factor 512 a specific restriction is applied. When the code word $C_{ch,512,n}$, with n = 0, 2, 4 … 510, is used in soft handover, then the code word $C_{ch,512,n+1}$ is not allocated in the cells where timing adjustment is to be used. Respectively if $C_{ch,512,n}$, with n = 1, 3, 5 … 511 is used, then the code word $C_{ch,512,n-1}$ is not allocated in the cells where timing adjustment is to be used. This restriction shall not apply in cases where timing adjustments in soft handover are not used with spreading factor 512.

When compressed mode is implemented by reducing the spreading factor by 2, the OVSF code used for compressed frames is:

-     $C_{ch,SF/2,\lfloor n/2 \rfloor}$ if ordinary scrambling code is used;

-     $C_{ch,SF/2,n \bmod SF/2}$ if alternative scrambling code is used (see clause 5.2.2);

where $C_{ch,SF,n}$ is the channelization code used for non-compressed frames.

5.2.2   Scrambling code

A total of $2^{18} - 1 = 262,143$ scrambling codes, numbered 0…262,142 can be generated. However not all the scrambling codes are used. The scrambling codes are divided into 512 sets each of a primary scrambling code and 15 secondary scrambling codes.

The primary scrambling codes consist of scrambling codes n = 16 x i where i = 0…511. The i:th set of secondary scrambling codes consists of scrambling codes 16 x i + k, where k = 1…15.

There is a one-to-one mapping between each primary scrambling code and 15 secondary scrambling codes in a set such that i:th primary scrambling code corresponds to i:th set of secondary scrambling codes.

Hence, according to the above, scrambling codes k = 0, 1, …, 8 191 are used. Each of these codes are associated with a left alternative scrambling code and a right alternative scrambling code, that may be used for compressed frames. The left alternative scrambling code corresponding to scrambling code k is scrambling code number k + 8 192, while the right alternative scrambling code corresponding to scrambling code k is scrambling code number k + 16 384. The alternative scrambling codes can be used for compressed frames. In this case, the left alternative scrambling code is used if n < SF / 2 and the right alternative scrambling code is used if n≥SF/2, where $c_{ch,SF,n}$ is the channelization code used for non-compressed frames. The usage of alternative scrambling code for compressed frames is signalled by higher layers for each physical channel respectively.

The set of primary scrambling codes is further divided into 64 scrambling code groups, each consisting of 8 primary scrambling codes. The j:th scrambling code group consists of primary scrambling codes 16 x 8 x j + 16 x k, where j = 0 ... 63 and k = 0 ... 7.

Each cell is allocated one and only one primary scrambling code. The primary CCPCH, primary CPICH, PICH, MICH, AICH and S-CCPCH carrying PCH are always transmitted using the primary scrambling code. The other downlink physical channels can be transmitted with either the primary scrambling code or a secondary scrambling code from the set associated with the primary scrambling code of the cell.

The mixture of primary scrambling code and no more than one secondary scrambling code for one CCTrCH is allowable. In compressed mode during compressed frames, these can be changed to the associated left or right scrambling codes as described above, i.e. in these frames, the total number of different scrambling codes may exceed two.

The scrambling code sequences are constructed by combining two real sequences into a complex sequence. Each of the two real sequences are constructed as the position wise modulo 2 sum of 38 400 chips segments of two binary *m*-sequences generated by means of two generator polynomials of degree 18. The resulting sequences thus constitute segments of a set of Gold sequences. The scrambling codes are repeated for every 10 ms radio frame. Let *x* and *y* be the two sequences respectively. The *x* sequence is constructed using the primitive (over GF(2)) polynomial $1 + X^7 + X^{18}$. The y sequence is constructed using the polynomial $1 + X^5 + X^7 + X^{10} + X^{18}$.

The sequence depending on the chosen scrambling code number *n* is denoted z_n, in the sequel. Furthermore, let $x(i)$, $y(i)$ and $z_n(i)$ denote the *i*:th symbol of the sequence *x*, *y*, and z_n, respectively.

The *m*-sequences *x* and *y* are constructed as:

Initial conditions:

- x is constructed with x (0) = 1, x(1) = x(2) = ... = x (16) = x (17) = 0.

- y(0) = y(1) = … = y(16) = y(17) = 1.

Recursive definition of subsequent symbols:

- x(i + 18) = x(i + 7) + x(i) modulo 2, i = 0,…,2^{18} - 20.

- y(i + 18) = y(i + 10) + y(i + 7) + y(i + 5) + y(i) modulo 2, i = 0,…, 2^{18} - 20.

The n:th Gold code sequence z_n, n = 0,1,2,…,2^{18} - 2, is then defined as:

- z_n(i) = x((i + n) modulo (2^{18} - 1)) + y(i) modulo 2, i = 0,…, 2^{18} - 2.

These binary sequences are converted to real valued sequences Z_n by the following transformation:

$$Z_n(i) = \begin{cases} +1 & if \ z_n(i) = 0 \\ -1 & if \ z_n(i) = 1 \end{cases} \quad for \quad i = 0,1,…,2^{18} - 2.$$

Finally, the n:th complex scrambling code sequence $S_{dl,n}$ is defined as:

- $S_{dl,n}$(i) = Z_n(i) + j Z_n((i + 131 072) modulo (2^{18} - 1)), i = 0, 1, … , 38 399.

Note that the pattern from phase 0 up to the phase of 38 399 is repeated.
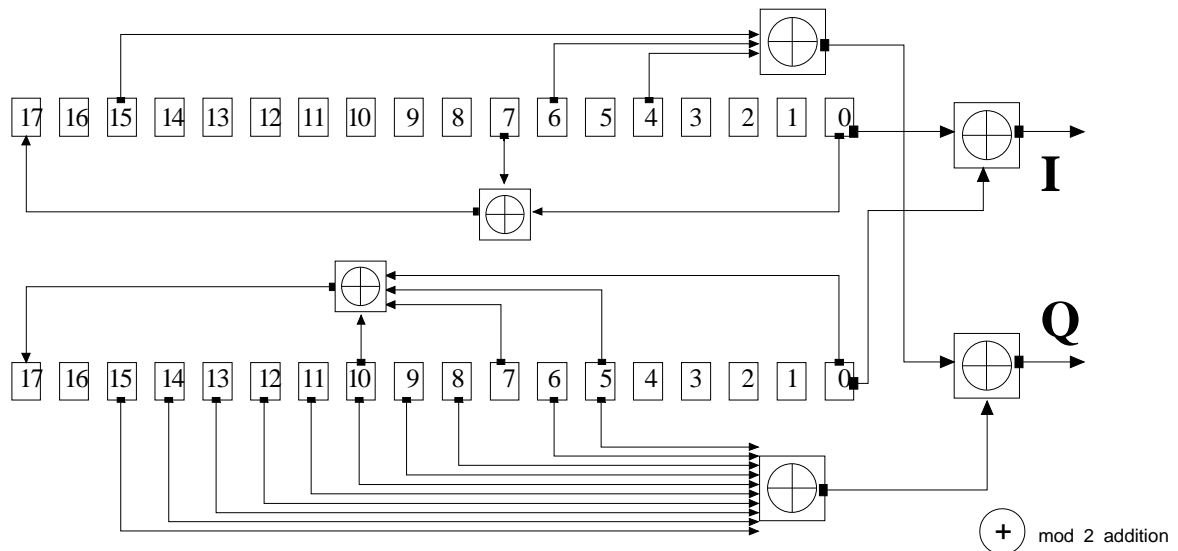

Figure 9: Configuration of downlink scrambling code generator

5.2.3   Synchronization codes

5.2.3.1   Code generation for normal operation

The following shall apply in all modes, except optional mode C.

The Primary Synchronization Code (PSC), C_{psc} is constructed as a so-called generalized hierarchical Golay sequence. The PSC is furthermore chosen to have good aperiodic auto correlation properties.

Define:

-       $a = <x_1, x_2, x_3, …, x_{16}> = <1, 1, 1, 1, 1, 1, -1, -1, 1, -1, 1, -1, 1, -1, -1, 1>$.

The PSC is generated by repeating the sequence a modulated by a Golay complementary sequence, and creating a complex-valued sequence with identical real and imaginary components. The PSC C_{psc} is defined as:

-       $C_{psc} = (1 + j) \times <a, a, a, -a, -a, a, -a, -a, a, a, a, -a, a, -a, a, a>$,

where the leftmost chip in the sequence corresponds to the chip transmitted first in time.

The 16 secondary synchronization codes (SSCs), $\{C_{ssc,1},…,C_{ssc,16}\}$, are complex-valued with identical real and imaginary components, and are constructed from position wise multiplication of a Hadamard sequence and a sequence z, defined as:

-       $z = <b, b, b, -b, b, b, -b, -b, b, -b, b, -b, -b, -b, -b, -b>$, where

-       $b = <x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, -x_9, -x_{10}, -x_{11}, -x_{12}, -x_{13}, -x_{14}, -x_{15}, -x_{16}>$ and $x_1, x_2, …, x_{15,} x_{16,}$ are same as in the definition of the sequence a above.

The Hadamard sequences are obtained as the rows in a matrix H_8 constructed recursively by:

$$H_0 = (1)$$
$$H_k = \begin{pmatrix} H_{k-1} & H_{k-1} \\ H_{k-1} & -H_{k-1} \end{pmatrix}, \quad k \geq 1$$

The rows are numbered from the top starting with row 0 (the all ones sequence).

Denote the n:th Hadamard sequence as a row of H_8 numbered from the top, n = 0, 1, 2, …, 255, in the sequel.

Furthermore, let $h_n(i)$ and $z(i)$ denote the i:th symbol of the sequence h_n and z, respectively where $i = 0, 1, 2, \ldots, 255$ and $i = 0$ corresponds to the leftmost symbol.

The k:th SSC, $C_{ssc,k}$, $k = 1, 2, 3, \ldots, 16$ is then defined as:

-       $C_{ssc,k} = (1 + j) \times <h_m(0) \times z(0), h_m(1) \times z(1), h_m(2) \times z(2), \ldots, h_m(255) \times z(255)>$,

    where $m = 16 \times (k - 1)$ and the leftmost chip in the sequence corresponds to the chip transmitted first in time.

5.2.3.2   Code generation for optional mode C

In optional mode C, the following shall apply :

The primary synchronisation code (PSC), C_{psc} is constructed as two so-called generalised hierarchical Golay sequences. The PSC is furthermore chosen to have good aperiodic auto correlation properties.

Define:

-       $a_1 = <x_1, x_2, x_3, \ldots, x_{16}> = <1, -1, 1, -1, -1, -1, -1, -1, 1, 1, -1, -1, -1, 1, 1, -1>$

-       $a_2 = <y_1, y_2, y_3, \ldots, y_{16}> = <1, -1, 1, -1, -1, -1, 1, 1, 1, -1, -1, 1, -1, -1, -1, -1>$

The PSC is generated by repeating the sequences a_1 and a_2 modulated by a Golay complementary sequence, and creating a complex-valued sequence with identical real and imaginary components. The PSC C_{psc} is defined as:

-       $C_{psc} = (1 + j) \times < a_1, -a_1, -a_1, -a_1, -a_1, a_1, -a_1, -a_1, a_2, a_2, -a_2, a_2, -a_2, a_2, a_2, a_2>$;

where the leftmost chip in the sequence corresponds to the chip transmitted first in time.

The 16 secondary synchronization codes (SSCs), $\{C_{ssc,1}, \ldots, C_{ssc,16}\}$, are complex-valued with identical real and imaginary components, and are constructed from position wise multiplication of a Hadamard sequence and a sequence z, defined as:

-       $z = <b_1, b_1, b_1, b_1, b_1, b_1, -b_1, -b_1, b_2, -b_2, -b_2, b_2, b_2, -b_2, b_2, -b_2>$, where

-       $b_1 = <x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, -x_9, -x_{10}, -x_{11}, -x_{12}, -x_{13}, -x_{14}, -x_{15}, -x_{16}>$ and $x_1, x_2, \ldots, x_{15}, x_{16}$, are the same as in the definition of the sequence a_1 above.

-       $b_2 = <y_1, y_2, y_3, y_4, y_5, y_6, y_7, y_8, -y_9, -y_{10}, -y_{11}, -y_{12}, -y_{13}, -y_{14}, -y_{15}, -y_{16}>$ and $y_1, y_2, \ldots, y_{15}, y_{16}$, are the same as in the definition of the sequence a_2 above.

The Hadamard sequences are obtained as the rows in a matrix H_8 constructed recursively by:

$$H_0 = (1)$$
$$H_k = \begin{pmatrix} H_{k-1} & H_{k-1} \\ H_{k-1} & -H_{k-1} \end{pmatrix}, \quad k \geq 1$$

The rows are numbered from the top starting with row 0 (the all ones sequence).

Denote the n:th Hadamard sequence as a row of H_8 numbered from the top, n = 0, 1, 2, …, 255, in the sequel.

Furthermore, let $h_n(i)$ and $z(i)$ denote the i:th symbol of the sequence h_n and z, respectively where $i = 0, 1, 2, \ldots, 255$ and $i = 0$ corresponds to the leftmost symbol.

The k:th SSC, $C_{ssc,k}$, $k = 1, 2, 3, \ldots, 16$ is then defined as:

-       $C_{ssc,k} = (1 + j) \times <h_m(0) \times z(0), h_m(1) \times z(1), h_m(2) \times z(2), \ldots, h_m(255) \times z(255)>$;

where $m = 8 \times (k - 1)$ and the leftmost chip in the sequence corresponds to the chip transmitted first in time.

5.2.3.3   Code allocation of SSC

The 64 secondary SCH sequences are constructed such that their cyclic-shifts are unique, i.e. a non-zero cyclic shift less than 15 of any of the 64 sequences is not equivalent to some cyclic shift of any other of the 64 sequences. Also, a non-zero cyclic shift less than 15 of any of the sequences is not equivalent to itself with any other cyclic shift less than 15. Table 4 describes the sequences of SSCs used to encode the 64 different scrambling code groups. The entries in table 4 denote what SSC to use in the different slots for the different scrambling code groups, e.g. the entry "7" means that SSC $C_{ssc,7}$ shall be used for the corresponding scrambling code group and slot.

Table 4: Allocation of SSCs for secondary SCH

5.3   Modulation

5.3.1   Modulating chip rate

The modulating chip rate is 3,84 Mcps.

5.3.2   Modulation

Modulation of the complex-valued chip sequence generated by the spreading process is shown in figure 10.

Figure 10: Downlink modulation

Annex A (informative):
Generalized Hierarchical Golay Sequences

A.1   Alternative generation

The generalized hierarchical Golay sequences for the PSC described in clause 5.2.3.1 may be also viewed as generated (in real valued representation) by the following methods:

Method 1

The sequence y is constructed from two constituent sequences x_1 and x_2 of length n_1 and n_2 respectively using the following formula:

-    $y(i) = x_2(i \bmod n_2) \times x_1(i \operatorname{div} n_2)$, i = 0 ... $(n_1 \times n_2)$ - 1.

The constituent sequences x_1 and x_2 are chosen to be the following length 16 (i.e. $n_1 = n_2 = 16$) sequences:

-    x_1 is defined to be the length 16 ($N^{(1)} = 4$) Golay complementary sequence obtained by the delay matrix $D^{(1)} = [8, 4, 1, 2]$ and weight matrix $W^{(1)} = [1, -1, 1, 1]$.

-    x_2 is a generalized hierarchical sequence using the following formula, selecting s = 2 and using the two Golay complementary sequences x_3 and x_4 as constituent sequences. The length of the sequence x_3 and x_4 is called n_3 respectively n_4.

-    $x_2(i) = x_4(i \bmod s + s \times (i \operatorname{div} sn_3)) \times x_3((i \operatorname{div} s) \bmod n_3)$, i = 0 ... $(n_3 \times n_4)$ - 1.

-    x_3 and x_4 are defined to be identical and the length 4 ($N^{(3)} = N^{(4)} = 2$) Golay complementary sequence obtained by the delay matrix $D^{(3)} = D^{(4)} = [1, 2]$ and weight matrix $W^{(3)} = W^{(4)} = [1, 1]$.

The Golay complementary sequences x_1, x_3 and x_4 are defined using the following recursive relation:

$a_0(k) = \delta(k)$ and $b_0(k) = \delta(k)$;

$a_n(k) = a_{n-1}(k) + W^{(j)}{}_n \cdot b_{n-1}(k - D^{(j)}{}_n)$;

$b_n(k) = a_{n-1}(k) - W^{(j)}{}_n \cdot b_{n-1}(k - D^{(j)}{}_n)$;

$\quad k = 0, 1, 2, \ldots, 2 \times\times N^{(j)} - 1$;

$\quad n = 1, 2, \ldots, N^{(j)}$.

The wanted Golay complementary sequence x_j is defined by a_n assuming $n = N^{(j)}$. The Kronecker delta function is described by δ, k, j and n are integers.

Method 2

The sequence y can be viewed as a pruned Golay complementary sequence and generated using the following parameters which apply to the generator equations for a and b above:

(a)   Let j = 0, $N^{(0)} = 8$.

(b) $[D_1^0, D_2^0, D_3^0, D_4^0, D_5^0, D_6^0, D_7^0, D_8^0] = [128, 64, 16, 32, 8, 1, 4, 2]$.

(c) $[W_1^0, W_2^0, W_3^0, W_4^0, W_5^0, W_6^0, W_7^0, W_8^0] = [1, -1, 1, 1, 1, 1, 1, 1]$.

(d)   For n = 4, 6, set $b_4(k) = a_4(k)$, $b_6(k) = a_6(k)$.

Annex B (normative):
Description of G-family enhancements

B.1   Definition of the optional modes A and C

The following two optional modes are defined in the G-family enhancements.

- Optional mode A: Operation with G-family features and A-family optional features which are identified in clause B.2 for performance enhancement.

- Optional mode C: Operation with G-family features and C-family optional features which are identified in clause B.3 for performance enhancement.

In order to keep backward compatibility with G family, the G-family enhancements system should support G basic terminals as well as G enhanced terminals and the G enhanced terminals should be operated in the G family system. For this, the following terminal types are considered in the G-family enhancements system.

- Terminal type 1 including only G-family interface

- Terminal type 2 including G-family interface as well as optional mode A

- Terminal type 3 including G-family interface as well as optional mode C

- Terminal type 4 including G-family interface as well as both optional modes A and C

The information which types of terminals are supported in the targeted frame and/or the considered Base Station could be sent via broadcasting channel.

B.2   Description of Optional mode A

The following new features of SRI-A family are considering for the standardization of SRI-G-family enhancements. They are based on a synthetic view of SW-CDMA and WCDMA identified in TR 102 278 [i.1].

Table B.1: Description of A-family optional features

Features	Description
HPPICH	- Additional paging channel - Unspread BPSK signal packet of length 10 ms - Channel rate = 15 k symbol/s - Packet = preamble (24bits) +UW (12 bits) + data (114 bits)
Downlink data scrambling	- For downlink when interference mitigation is used - Prior to physical channel mapping - By a ML sequence with polynomial $1+X^{14}+X^{15}$ - Rate: 30 kbit/s

B.3   Description of Optional mode C

The following new features of SRI-C family are considering for the standardization of SRI-G-family enhancements.

Table B.2: Description of C-family optional features

Features	Description
Uplink random access	- Transmission of both preamble and message, together - Access frame: 2 radio frames
FBI/TPC bits generation and transmission	- TPC field: the reduction of the half of TPC field - FBI field: removal of 2 bits FBI filed
Power control	- CLPC: a delay compensation power control scheme + prediction algorithm - SIR estimation from CPICH and S-CCPCH - 2-bit TPC command - OLPC algorithm using pilot diversity in option
Synchronization codes for downlink SCH in LEO constellation	- One so-called generalized hierarchical Golay sequence

Annex C (informative):
Change history

This annex describes the differences relevant to TS 101 851-1-1 [i.3], TS 101 851-1-2 [i.4], TS 101 851-2-1 [i.5], TS 101 851-2-2 [i.6], TS 101 851-3-1 [i.7], TS 101 851-3-2 [i.8], TS 101 851-4-1 [i.9] and TS 101 851-4-2 [i.10].

C.1   A-family optional features

The following tables present summary on changes for TS 101 851-1-3 [1] to TS 101 851-4-3 [3] of SRI-G family, considering the harmonization with SRI-A family.

Table C.1: TS 101 851-1-3 [1]; Physical channels and mapping of transport channels into physical channels

Item Reference	Item	Actions
3.2 Abbreviations	- HPPICH for optional mode A	- To add HPPICH for high penetration paging
5.3.2.8 High penetration page indication channel	- HPICCH for optional mode A	- To define HPPICH for high penetration paging + Unspread BPSK signal packet of length 10 ms + Channel rate = 15 ksymbol/s + Packet = Preamble (24 bits) + UW (12 bits) + data (114 bits)

Table C.2: TS 101 851-2-3 [2]; Multiplexing and channel coding

Item Reference	Item	Actions
4.2 General coding/multiplexing of TrCHs	- Downlink data scrambling for optional mode A	- To add downlink data scrambling step between 2nd interleaving and physical mapping
4.2.15 Downlink data scrambling	- Downlink data scrambling for optional mode A	- To define downlink data scrambling + A ML sequence with polynomial $1+X14+X15$ + Rate: 30 kbit/s

C.2   C-family optional features

The following tables present summary on changes for TS 101 851-1-3 [1] to TS 101 851-4-3 [3] of SRI-G family, considering the harmonization with SRI-C family.

Table C.3: TS 101 851-1-3 [1]; Physical channels and mapping of transport channels into physical channels

Item Reference	Item	Actions
5.2.1 Dedicated uplink physical channels	- FBI/TPC field generation for the optional mode C	- Addition of statement related to deletion of FBI field for closed-loop transmit diversity and reduction as 1 bit for only SSDT - Reduction of the number of slot formats: Deletion of 2 bits FBI - Reduction of TPC field and extension of pilot field - Identification of new pilot patterns
5.2.2 Common uplink physical channels	- Uplink random access for the optional mode C	- Addition of modified structure of random-access transmission: transmission of both a preamble and a message - Identification of access frame - Based on ALOHA approach with fast acquisition indication - Optional RACH preamble: Np repetition of a sub-preamble and conjugation in the final sub-preamble
6.3.1 Dedicated downlink physical channels	- FBI/TPC field generation for the optional mode C	- Modification of TPC duration as one radio frame - Reduction of the TPC field as 1/2 and extension of the Data2 field
6.3.2 Common downlink physical channels	- Uplink random access for the optional mode C	- Identification on transmission of AI only on the first and 9th access slots
8.1 Timing relation between physical channels	- Uplink random access for the optional mode C	- Identification on AICH sub-access frame
8.3 PRACH/AICH timing relation	- Uplink random access for the optional mode C	- Identification of modified PRACH/AICH timing relation in order to consider long round trip delay of satellite system and transmission of both preamble and message parts

Table C.4: TS 101 851-2-3 [2]; Multiplexing and channel coding

Item Reference	Item	Actions
4.5 TPC command coding	- FBI/TPC field generation for the optional mode C	- Identification of a new coding method of TPC command: 8 repetition of 2 bits TPC command - Identification of mapping of TPC words

Table C.5: TS 101 851-3-3; Spreading and modulation

Item Reference	Item	Actions
5.3.3 PRACH preamble codes	- Uplink random access transmission for the optional mode C	- Addition of new code construction: Nsp repetition of a sub-preamble and conjugation in the final sub-preamble - Identification of usage of other codes in order to distinguish even and odd sub-access frames
6.2.3 Synchronization codes	- Synchronization codes for downlink SCH in LEO constellation	- Identification of a new code generation method for LEO based mobile satellite system - Addition of modified synchronization codes as two hierarchical Golay sequences with 128 chip length

Table C.6: TS 101 851-4-3 [3]; Physical layer procedure

Item Reference	Item	Actions
5.1 Uplink power control	- Power control method for the optional mode C	- Identification of one power control per one frame duration - Identification of a new closed-loop power control with delay compensation algorithm in order to optimize the basic power control loop parameters, including the power control rate, power control step size, and the number of control levels - Identification of a new open-loop power control algorithm considering pilot diversity
5.2 Downlink power control	- Synchronization codes for downlink SCH in LEO constellation for the optional mode C	- Identification of one power control per one frame duration - Identification of a new closed-loop power control with delay compensation and prediction algorithms in order to optimize the basic power control loop parameters, including the power control rate, power control step size, and the number of control levels - Deletion of ID codes for 2 bit FBI in spot selection diversity transmit power control
6.1 Random access procedure	- Uplink random access transmission for the optional mode C	- Identification of access frame, even access frame and odd access frame - Identification of a new PRACH procedure with addition to selection of sub-access frame
6.1.1 RACH sub-channels	- Uplink random access transmission for the optional mode C	- Identification of a RACH sub-channel as a set of access frame
6.1.2 RACH access frame sets	- Uplink random access transmission for the optional mode C	- Identification of a new RACH access frame sets
