Intellectual Property Rights

Essential patents

IPRs essential or potentially essential to normative deliverables may have been declared to ETSI. The declarations pertaining to these essential IPRs, if any, are publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "*Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards*", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<https://ipr.etsi.org/>).

Pursuant to the ETSI Directives including the ETSI IPR Policy, no investigation regarding the essentiality of IPRs, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Trademarks

The present document may include trademarks and/or tradenames which are asserted and/or registered by their owners. ETSI claims no ownership of these except for any which are indicated as being the property of ETSI, and conveys no right to use or reproduce any trademark and/or tradename. Mention of those trademarks in the present document does not constitute an endorsement by ETSI of products, services or organizations associated with those trademarks.

DECT™, **PLUGTESTS™**, **UMTS™** and the ETSI logo are trademarks of ETSI registered for the benefit of its Members. **3GPP™** and **LTE™** are trademarks of ETSI registered for the benefit of its Members and of the 3GPP Organizational Partners. **oneM2M™** logo is a trademark of ETSI registered for the benefit of its Members and of the oneM2M Partners. **GSM®** and the GSM logo are trademarks registered and owned by the GSM Association.

Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee TETRA and Critical Communications Evolution (TCCE).

The present document is part 2 of a multi-part deliverable covering the specifications of the TETRA standard encryption, authentication and key management algorithms, as identified below:

- Part 1: "TETRA Encryption Algorithms Set A";
- Part 2: "TETRA Encryption Algorithms TEA Set B";**
- Part 3: "TETRA and Authentication and Key Management Algorithms TAA1";
- Part 4: "TETRA Authentication and Key Management Algorithms TAA2".

Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the [ETSI Drafting Rules](#) (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

1 Scope

The present document specifies the Terrestrial Trunked Radio system (TETRA) set B encryption algorithms TEA 5, 6 and 7. These algorithms are designed to meet the requirements set out in the requirements specification for the Additional TETRA Encryption Algorithm Suite [i.2].

The TETRA Air interface security function provides mechanisms for confidentiality of control signalling and user speech and data at the air interface, authentication and key management mechanisms for the air interface and for the Inter-System Interface (ISI). TETRA Air Interface security mechanisms are described in the TETRA V+D security specification [1] and the TETRA Direct Mode security specification [2].

2 References

2.1 Normative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at <https://docbox.etsi.org/Reference/>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long-term validity.

The following referenced documents are necessary for the application of the present document:

- [1] [ETSI TS 100 392-7](#): "Terrestrial Trunked Radio (TETRA); Voice plus Data (V+D); Part 7: Security".
- [2] [ETSI TS 100 396-6](#): "Terrestrial Trunked Radio (TETRA); Direct Mode Operation (DMO); Part 6: Security".

2.2 Informative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are not necessary for the application of the present document but they assist the user with regard to a particular subject area.

- [i.1] [Daemen, J. and Rijmen, V. \(1999\)](#): "AES proposal: Rijndael", document version 2". Submission to NIST AES competition (1999).

3 Definition of terms, symbols and abbreviations

3.1 Terms

For the purposes of the present document, the following terms apply:

Cipher Key (CK): value that is used to determine the transformation of plain text to cipher text in a cryptographic algorithm

Initialization Vector (IV): sequence of symbols that randomize the KSG inside the encryption unit

key stream: pseudo random stream of symbols that is generated by a KSG for encipherment and decipherment

Key Stream Generator (KSG): cryptographic algorithm which produces a stream of binary digits, which can be used for encipherment and decipherment

NOTE: The initial state of the KSG is determined by the IV value.

Key Stream Segment (KSS): key stream of arbitrary length

LENGTH: required length of the key stream in bits

TEA set A: set of air interface encryption algorithms comprising TEA1, TEA2, TEA3 and TEA4

TEA set B: set of air interface encryption algorithms comprising TEA5, TEA6 and TEA7

TETRA algorithm: mathematical description of a cryptographic process used for either of the security processes authentication or encryption

3.2 Symbols

Void.

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

| | |
|-----|------------------------|
| CK | Cipher Key |
| CKM | Mode Key |
| GF | Galois Field |
| IV | Initialization Vector |
| IVM | Mode IV |
| IVX | eXpanded IV |
| KSS | Key Stream Segment |
| ISI | Inter System Interface |
| KSG | Key Stream Generator |

4 TEA encryption Set B Algorithm specifications

4.1 Input and Output Parameters

As specified in clause 8.3 of [i.2], the input parameters to the algorithm are:

- an initialization vector IV consisting of 80 bits IV[0], ..., IV[79];
- a cipher key CK consisting of 192 bits CK[0], ..., CK[191];

- the required length LENGTH of the key stream in bits. This can, according to [i.2], take any value from 1 up to 8 288. However, the design of the algorithm allows it to deliver, securely, a length of keystream up to 2^{40} bits, making it potentially suitable for future applications where an increased length of KSS output is required.

The corresponding output from the algorithm is then a key stream segment KSS consisting of LENGTH bits KSS[0], ..., KSS[LENGTH-1].

5 TEA5 - Specification of the Algorithm

5.1 Introduction

In outline, the algorithm operates as follows:

- the 80 bits of initialization vector IV, considered as 10 elements of the Galois field $GF(2^8)$, are mixed using a 10-stage linear recursion over $GF(2^8)$ to give 24 bytes which form a 192-bit mixed initialization vector IVX;
- the cipher key CK and mixed initialization vector IVX are combined to produce a 192-bit Mode Key, CKM, and a 192-bit Mode IV, IVM;
- successive 256-bit blocks are formed as a concatenation Mode IV || 'T', 'E', 'A', 'S' || counter, where the byte values 'T', 'E', 'A', 'S' code the name of the algorithm in ASCII, and the 32-bit counter takes successive values 0, 1, ...;
- these successive 256-blocks are encrypted using the variant of Rijndael [i.1] with parameters giving a block length of 256 bits and key length 192 bits. The Mode Key is used as the Rijndael key. The 256-bit blocks obtained as a result of these Rijndael encryptions are concatenated to form KSS; some bits will be discarded from the final ciphertext block if LENGTH is not exactly divisible by 256.

The algorithm is specified precisely in clauses 5.2 to 5.6.

5.2 TEA5 IV Expansion

The 80-bit IV is expanded to a 192-bit mixed IV, IVX, as follows:

- from the initialization vector bits IV[0], ..., IV[79], form 10 bytes b[0], ..., b[9], where $b[i] = 2^7 IV[8 \times i] + 2^6 IV[8 \times i + 1] + \dots + IV[8 \times i + 7]$, for $i = 0, \dots, 9$;
- for any bits B[0], ..., B[7], the byte is identified as $2^7 B[0] + 2^6 B[1] + \dots + B[7]$ with the element $z^7 B[0] + z^6 B[1] + \dots + B[7]$ of $GF(2^8)$, where z is a generator of $GF(2^8)$ satisfying the Rijndael polynomial $x^8 + x^4 + x^3 + x + 1$ in $GF(2)[x]$;
- for $i = 10, \dots, 43$, a byte b[i] is obtained from bytes b[i-1], ..., b[i-10] according to the rule $b[i] = b[i-10] \oplus b[i-9] \oplus (z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$. The byte $(z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$ can be obtained from b[i-1] using the lookup table defined in clause 5.5;
- the 24 bytes b[20], b[21], ..., b[43] contain the bits IVX[0], ..., IVX[191], where $b[20+i] = 2^7 IVX[8i] + 2^6 IVX[8i + 1] + \dots + IVX[8i + 7]$ for $i = 0, \dots, 23$.

This process is illustrated in figures 1 and 2 below.

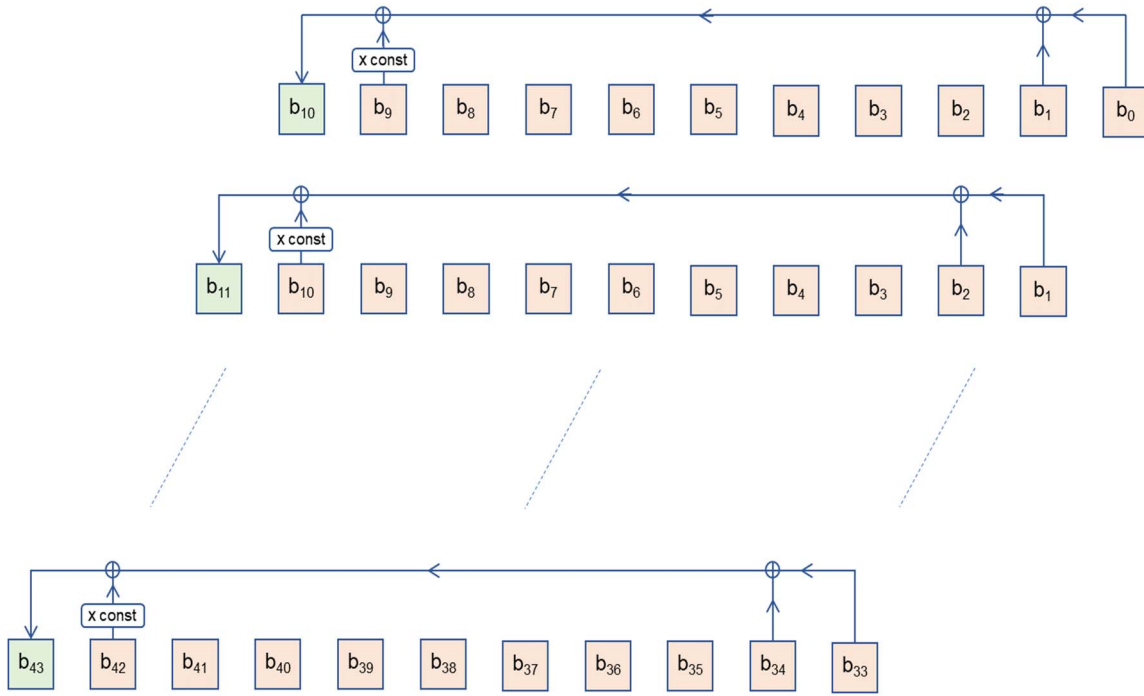

Figure 1: IV expansion

Figure 2: IVX extraction

5.3 TEA5 Derivation of the Mode Key and Mode IV

The Mode Key consists of 192 bits CKM[0], ..., CKM[191] and the Mode IV consists of 192 bits IVM[0], ..., IVM[191]. An 8-bit to 8-bit combining function f is applied to successive 8-bit inputs formed from 4 bits of the cipher key CK and 4 bits from the mixed initialization vector IVX, and the result is taken to be a further 4 bits of Mode Key and 4 bits of Mode IV. More precisely, for each i in the range 0, ..., 47,

$$2^7\text{CKM}[4i] + 2^6\text{CKM}[4i+1] + \dots + 2^4\text{CKM}[4i+3] + 2^3\text{IVM}[4i] + 2^2\text{IVM}[4i+1] + \dots + \text{IVM}[4i+3] = f(2^7\text{CK}[4i] + 2^6\text{CK}[4i+1] + \dots + 2^4\text{CK}[4i+3] + 2^3\text{IVX}[4i] + 2^2\text{IVX}[4i+1] + \dots + \text{IVX}[4i+3])$$

The combining function f is defined in clause 5.6.

The process for deriving the Mode Key and Mode IV from the cipher key CK and mixed initialization vector IVX is illustrated in figure 3 below.

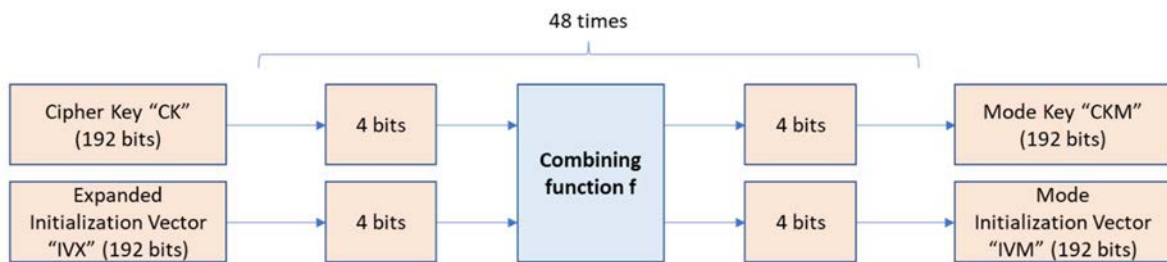

Figure 3: Mode Key and Mode IV derivation

5.4 TEA5 Derivation of the Keystream Bits

The keystream bits KSS are obtained using Rijndael [i.1] with key length 192 bits and block size 256 bits, used in a counter mode. The key used is the Mode Key CKM, arranged into bytes $2^7\text{CKM}[8i] + 2^6\text{CKM}[8i+1] + \dots + \text{CKM}[8i+7]$ for $i = 0, \dots, 23$. The Rijndael algorithm is run in encryption mode to encrypt $\lceil \text{LENGTH}/256 \rceil$ successive plaintext blocks, where the notation $\lceil \text{LENGTH}/256 \rceil$ denotes the least integer \geq the floating-point quotient $\text{LENGTH}/256$. The plaintext for encryption j , for $j = 0, \dots, \lceil \text{LENGTH}/256 \rceil - 1$, is, informally, $\text{IVM} \parallel \text{'T', 'E', 'A', '5'} \parallel j$, where the byte values 'T', 'E', 'A', '5' code the name of the algorithm in ASCII, and j is coded as 4 bytes; more precisely, it is the 32-byte sequence p_0, \dots, p_{31} , where:

- $p_i = 2^7\text{IVM}[8i] + 2^6\text{IVM}[8i+1] + \dots + \text{IVM}[8i+7]$ for $i = 0, \dots, 23$;
- $p_{24} = 84, p_{25} = 69, p_{26} = 65, p_{27} = 53$ (those four values being in decimal);
- $2^{24}p_{28} + 2^{16}p_{29} + 2^8p_{30} + p_{31} = j$.

The keystream bit $\text{KSS}[i]$ is the bit $C_s[t]$, which is written as:

- $i = 256r + 8s + t$, for $0 \leq s \leq 31$ and $0 \leq t \leq 7$;
- c_0, \dots, c_{31} are the ciphertext bytes obtained from the encryption where $j = r$;
- $c_s = 2^7C_s[0] + 2^6C_s[1] + \dots + C_s[7]$, for bits $C_s[0], \dots, C_s[7]$.

Note that if $(\text{LENGTH} \bmod 256) \leq 248$ then one or more higher numbered ciphertext bytes from the last block will be discarded. If $(\text{LENGTH} \bmod 8) > 0$ then one or more less significant bits from the last used ciphertext byte will be discarded.

Note that the maximum value of LENGTH, the number of bits of required keystream, is 8 288, according to the specification [i.2]. Since this maximum number of required keystream bits $\leq 2^{16}$, the 32-bit counter j can be implemented as an 8-bit counter with the other three bytes fixed to zero. If, in a future application, the maximum number of bits of required keystream is no more than 2^{24} bits, then the 32-bit counter can be implemented as a 16-bit counter with the other two bytes fixed to zero. If a full range of values for the 32-bit counter is implemented, keystream sequences of length up to 2^{40} can be generated.

The use of Rijndael in counter mode to produce keystream bits is shown in figure 4 below.

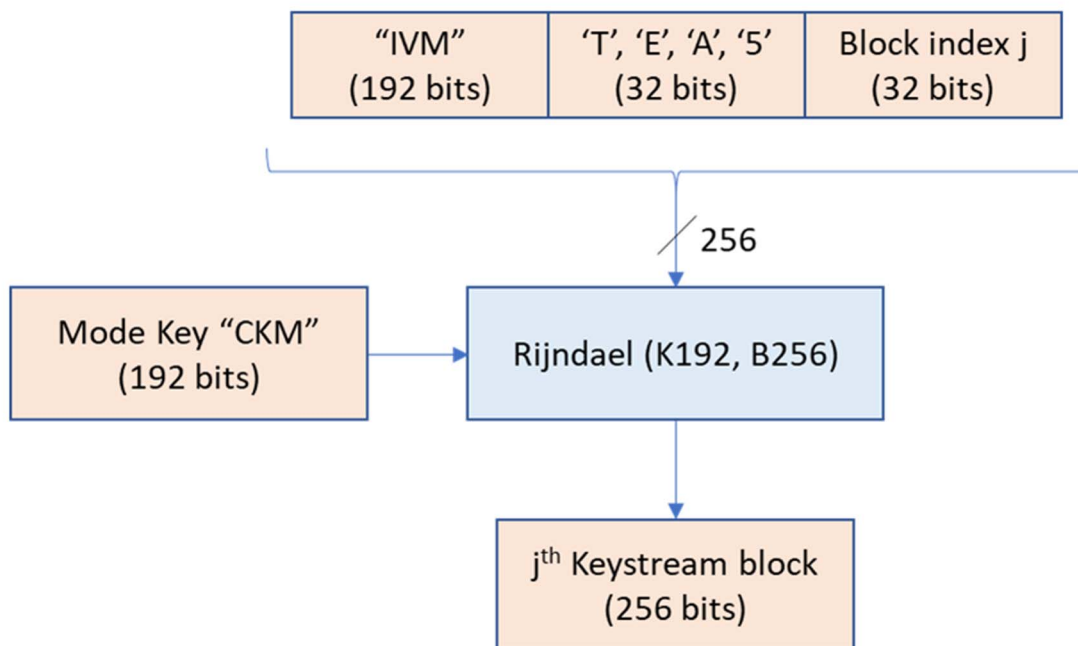

Figure 4: Keystream generation

5.5 TEA5 - Lookup Table for IV Mixing

Table 1 implements Galois Field multiplication by $z^7 + z^6 + z^4 + z^2 + z + 1$, as discussed in clause 5.2. Different rows correspond to different values of the most significant 4 bits of the input, and columns to the least significant 4 bits. For example, the value corresponding to 0x12 is found in the row labelled 0x1? and column labelled 0x?2, and is the byte value 0x6a.

5.6 TEA5 - Definition of the Combining Function f

Table 2 defines the combining function f, which is used as defined in clause 5.3. Different rows correspond to different values of the most significant 4 bits of the input, and columns to the least significant 4 bits. For example, the value corresponding to 0x12 is found in the row labelled 0x1? and column labelled 0x?2, and is the byte value 0xcc.

Table 2

| | 0x?0 | 0x?1 | 0x?2 | 0x?3 | 0x?4 | 0x?5 | 0x?6 | 0x?7 | 0x?8 | 0x?9 | 0x?a | 0x?b | 0x?c | 0x?d | 0x?e | 0x?f |

6 TEA6 - Specification of the Algorithm

6.1 Introduction

In outline, the algorithm operates as follows:

- the 80 bits of initialization vector IV, considered as 10 elements of the Galois field $GF(2^8)$, are mixed using a 10-stage linear recursion over $GF(2^8)$ to give 24 bytes which form a 192-bit mixed initialization vector IVX;
- the cipher key CK and mixed initialization vector IVX are combined to produce a 192-bit Mode Key, CKM, and a 192-bit Mode IV, IVM;
- successive 256-bit blocks are formed as a concatenation Mode IV || 'T', 'E', 'A', '6' || counter, where the byte values 'T', 'E', 'A', '6' code the name of the algorithm in ASCII, and the 32-bit counter takes successive values 0, 1, ...;
- these successive 256-blocks are encrypted using the variant of Rijndael [i.1] with parameters giving a block length of 256 bits and key length 192 bits. The Mode Key is used as the Rijndael key. The 256-bit blocks obtained as a result of these Rijndael encryptions are concatenated to form KSS; some bits will be discarded from the final ciphertext block if LENGTH is not exactly divisible by 256.

The algorithm is specified precisely in clauses 6.2 to 6.6.

6.2 TEA6 - IV Expansion

The 80-bit IV is expanded to a 192-bit mixed IV, IVX, as follows:

- from the initialization vector bits IV[0], ..., IV[79], form 10 bytes b[0], ..., b[9], where $b[i] = 2^7 IV[8 \times i] + 2^6 IV[8 \times i + 1] + \dots + IV[8 \times i + 7]$, for $i = 0, \dots, 9$;
- for any bits B[0], ..., B[7], the byte is identified as $2^7 B[0] + 2^6 B[1] + \dots + B[7]$ with the element $z^7 B[0] + z^6 B[1] + \dots + B[7]$ of $GF(2^8)$, where z is a generator of $GF(2^8)$ satisfying the Rijndael polynomial $x^8 + x^4 + x^3 + x + 1$ in $GF(2)[x]$;
- for $i = 10, \dots, 43$, a byte b[i] is obtained from bytes b[i-1], ..., b[i-10] according to the rule $b[i] = b[i-10] \oplus b[i-9] \oplus (z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$. The byte $(z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$ can be obtained from b[i-1] using the lookup table defined in clause 6.5;
- the 24 bytes b[20], b[21], ..., b[43] contain the bits IVX[0], ..., IVX[191], where $b[20+i] = 2^7 IVX[8i] + 2^6 IVX[8i + 1] + \dots + IVX[8i + 7]$ for $i = 0, \dots, 23$.

This process is illustrated in figures 5 and 6 below.

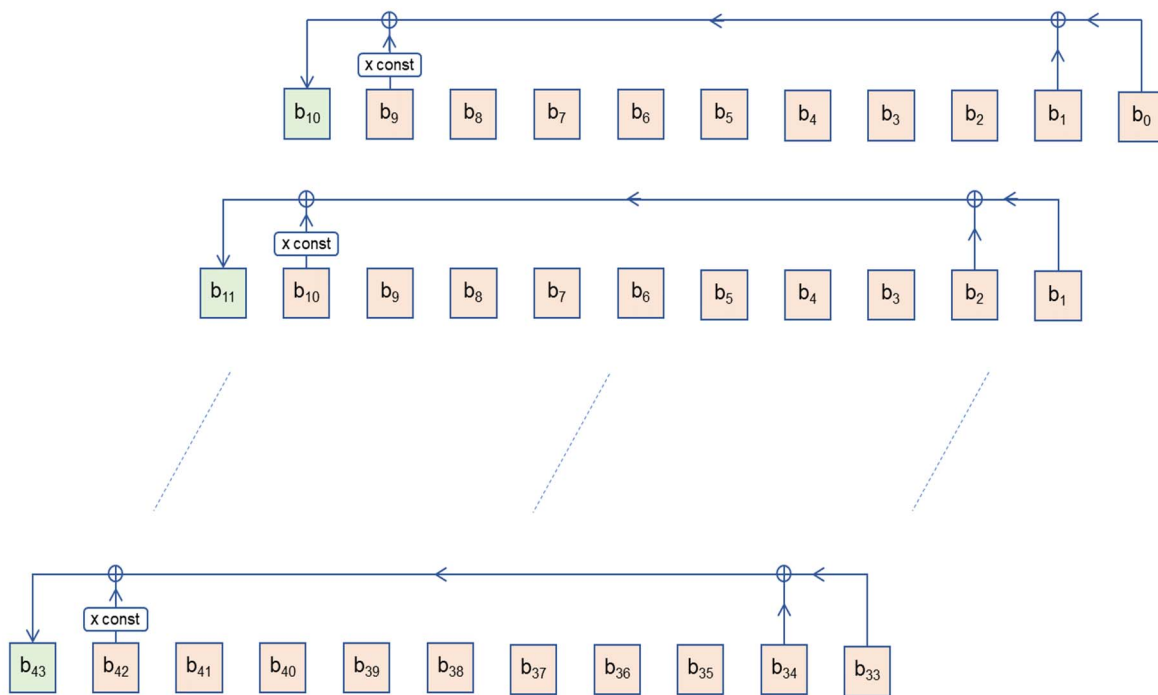

Figure 5: TEA6 - IV expansion

Figure 6: TEA6 - IVX extraction

6.3 TEA6 - Derivation of the Mode Key and Mode IV

The Mode Key consists of 192 bits $CKM[0], \dots, CKM[191]$ and the Mode IV consists of 192 bits $IVM[0], \dots, IVM[191]$. An 8-bit to 8-bit combining function f is applied to successive 8-bit inputs formed from 4 bits of the cipher key CK and 4 bits from the mixed initialization vector IVX , and the result is taken to be a further 4 bits of Mode Key and 4 bits of Mode IV. More precisely, for each i in the range $0, \dots, 47$,

$$2^7CKM[4i] + 2^6CKM[4i+1] + \dots + 2^4CKM[4i+3] + 2^3IVM[4i] + 2^2IVM[4i+1] + \dots + IVM[4i+3] = f(2^7CK[4i] + 2^6CK[4i+1] + \dots + 2^4CK[4i+3] + 2^3IVX[4i] + 2^2IVX[4i+1] + \dots + IVX[4i+3])$$

The combining function f is defined in clause 6.6.

The process for deriving the Mode Key and Mode IV from the cipher key CK and mixed initialization vector IVX is illustrated in figure 7 below.

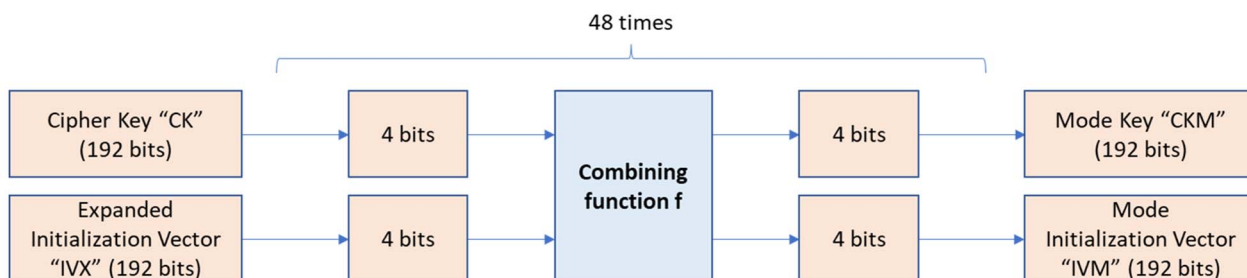

Figure 7: TEA6 Mode Key and Mode IV derivation

6.4 TEA6 - Derivation of the Keystream Bits

The keystream bits KSS are obtained using Rijndael [i.1] with key length 192 bits and block size 256 bits, used in a counter mode. The key used is the Mode Key CKM, arranged into bytes $2^7\text{CKM}[8i] + 2^6\text{CKM}[8i+1] + \dots + \text{CKM}[8i+7]$ for $i = 0, \dots, 23$. The Rijndael algorithm is run in encryption mode to encrypt $\lceil \text{LENGTH}/256 \rceil$ successive plaintext blocks, where the notation $\lceil \text{LENGTH}/256 \rceil$ denotes the least integer \geq the floating-point quotient $\text{LENGTH}/256$. The plaintext for encryption j , for $j = 0, \dots, \lceil \text{LENGTH}/256 \rceil - 1$, is, informally, $\text{IVM} \parallel \text{'T', 'E', 'A', '6'} \parallel j$, where the byte values 'T', 'E', 'A', '6' code the name of the algorithm in ASCII, and j is coded as 4 bytes; more precisely, it is the 32-byte sequence p_0, \dots, p_{31} , where:

- $p_i = 2^7\text{IVM}[8i] + 2^6\text{IVM}[8i+1] + \dots + \text{IVM}[8i+7]$ for $i = 0, \dots, 23$;
- $p_{24} = 84, p_{25} = 69, p_{26} = 65, p_{27} = 53$ (those four values being in decimal);
- $2^{24}p_{28} + 2^{16}p_{29} + 2^8p_{30} + p_{31} = j$.

The keystream bit $\text{KSS}[i]$ is the bit $\text{C}_s[t]$, where:

- it is written as $i = 256r + 8s + t$, for $0 \leq s \leq 31$ and $0 \leq t \leq 7$;
- c_0, \dots, c_{31} are the ciphertext bytes obtained from the encryption where $j = r$;
- $c_s = 2^7\text{C}_s[0] + 2^6\text{C}_s[1] + \dots + \text{C}_s[7]$, for bits $\text{C}_s[0], \dots, \text{C}_s[7]$.

Note that if $(\text{LENGTH} \bmod 256) \leq 248$ then one or more higher numbered ciphertext bytes from the last block will be discarded. If $(\text{LENGTH} \bmod 8) > 0$ then one or more less significant bits from the last used ciphertext byte will be discarded.

Note that the maximum value of LENGTH, the number of bits of required keystream, is 8 288, according to the specification [i.2]. Since this maximum number of required keystream bits $\leq 2^{16}$, the 32-bit counter j can be implemented as an 8-bit counter with the other three bytes fixed to zero. If, in a future application, the maximum number of bits of required keystream is no more than 2^{24} bits, then the 32-bit counter can be implemented as a 16-bit counter with the other two bytes fixed to zero. If a full range of values for the 32-bit counter is implemented, keystream sequences of length up to 2^{40} can be generated.

The use of Rijndael in counter mode to produce keystream bits is shown in figure 8 below.

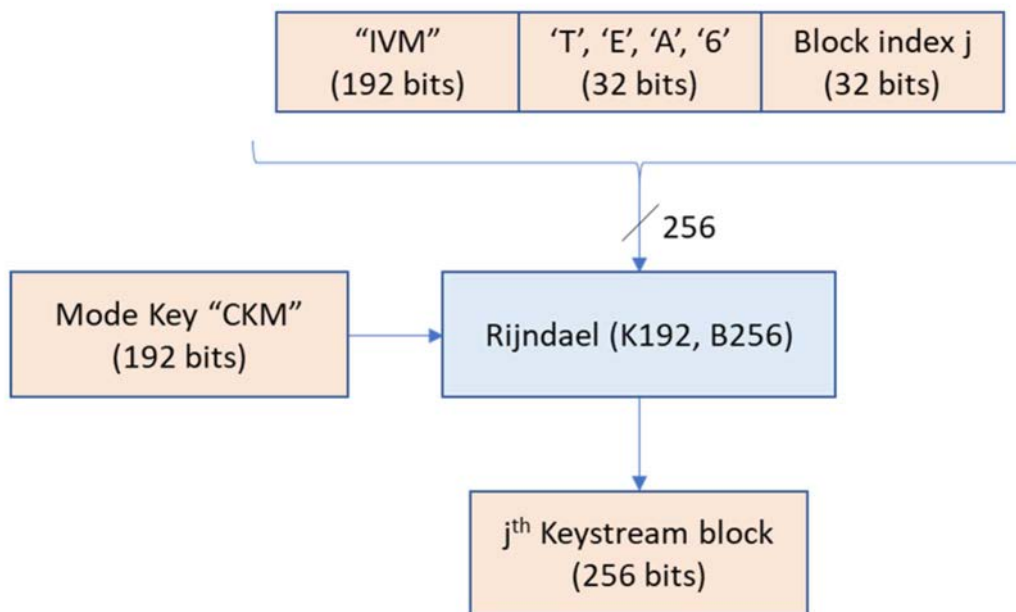

Figure 8: TEA6 Keystream generation

6.5 TEA6 - Lookup Table for IV Mixing

Table 3 implements Galois Field multiplication by $z^7 + z^6 + z^4 + z^2 + z + 1$, as discussed in clause 6.2. Different rows correspond to different values of the most significant 4 bits of the input, and columns to the least significant 4 bits. For example, the value corresponding to 0x12 is found in the row labelled 0x1? and column labelled 0x?2, and is the byte value 0x6a.

7 TEA7-Specification of the Algorithm

7.1 Introduction

In outline, the algorithm operates as follows:

- the 80 bits of initialization vector IV, considered as 10 elements of the Galois field $GF(2^8)$, are mixed using a 10-stage linear recursion over $GF(2^8)$ to give 24 bytes which form a 192-bit mixed initialization vector IVX;
- the cipher key CK and mixed initialization vector IVX are combined to produce a 192-bit Mode Key, CKM, and a 192-bit Mode IV, IVM;
- successive 256-bit blocks are formed as a concatenation Mode IV || 'T', 'E', 'A', '7' || counter, where the byte values 'T', 'E', 'A', '7' code the name of the algorithm in ASCII, and the 32-bit counter takes successive values 0, 1, ...;
- these successive 256-blocks are encrypted using the variant of Rijndael [i.1] with parameters giving a block length of 256 bits and key length 192 bits. The Mode Key is used as the Rijndael key. The 256-bit blocks obtained as a result of these Rijndael encryptions are concatenated to form KSS; some bits will be discarded from the final ciphertext block if LENGTH is not exactly divisible by 256.

The algorithm is specified precisely in clauses 7.2 to 7.6.

7.2 TEA7- IV Expansion

The 80-bit IV is expanded to a 192-bit mixed IV, IVX, as follows:

- from the initialization vector bits IV[0], ..., IV[79], form 10 bytes b[0], ..., b[9], where $b[i] = 2^7 IV[8 \times i] + 2^6 IV[8 \times i + 1] + \dots + IV[8 \times i + 7]$, for $i = 0, \dots, 9$;
- for any bits B[0], ..., B[7], the byte is identified as $2^7 B[0] + 2^6 B[1] + \dots + B[7]$ with the element $z^7 B[0] + z^6 B[1] + \dots + B[7]$ of $GF(2^8)$, where z is a generator of $GF(2^8)$ satisfying the Rijndael polynomial $x^8 + x^4 + x^3 + x + 1$ in $GF(2)[x]$;
- for $i = 10, \dots, 43$, a byte b[i] is obtained from bytes b[i-1], ..., b[i-10] according to the rule $b[i] = b[i-10] \oplus b[i-9] \oplus (z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$. The byte $(z^7 + z^6 + z^4 + z^2 + z + 1) b[i-1]$ can be obtained from b[i-1] using the lookup table defined in clause 7.5;
- the 24 bytes b[20], b[21], ..., b[43] contain the bits IVX[0], ..., IVX[191], where $b[20+i] = 2^7 IVX[8i] + 2^6 IVX[8i + 1] + \dots + IVX[8i + 7]$ for $i = 0, \dots, 23$.

This process is illustrated in figures 9 and 10 below.

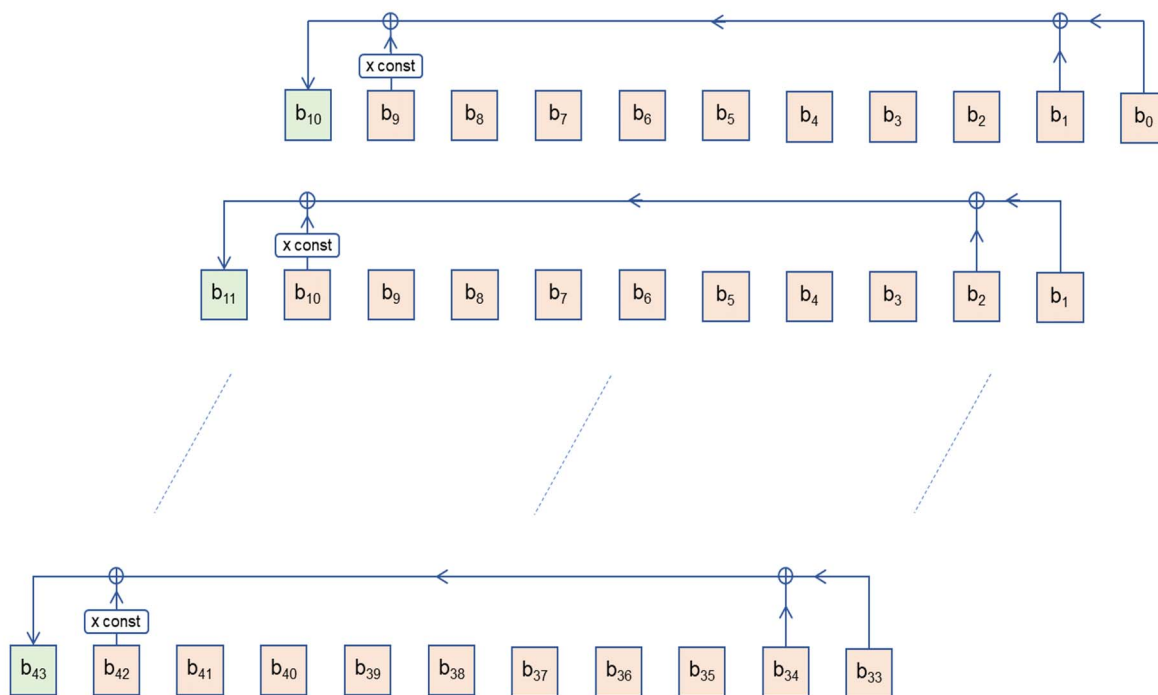

Figure 9: TEA7- IV expansion

Figure 10: TEA7- IVX extraction

7.3 TEA7- Derivation of the Mode Key and Mode IV

The Mode Key consists of 192 bits $CKM[0], \dots, CKM[191]$ and the Mode IV consists of 192 bits $IVM[0], \dots, IVM[191]$. An 8-bit to 8-bit combining function f is applied to successive 8-bit inputs formed from 4 bits of the cipher key CK and 4 bits from the mixed initialization vector IVX , and the result is taken to be a further 4 bits of Mode Key and 4 bits of Mode IV. More precisely, for each i in the range $0, \dots, 47$,

$$2^7CKM[4i] + 2^6CKM[4i+1] + \dots + 2^4CKM[4i+3] + 2^3IVM[4i] + 2^2IVM[4i+1] + \dots + IVM[4i+3] =$$

$$f(2^7CK[4i] + 2^6CK[4i+1] + \dots + 2^4CK[4i+3] + 2^3IVX[4i] + 2^2IVX[4i+1] + \dots + IVX[4i+3])$$

The combining function f is defined in clause 7.5.

The process for deriving the Mode Key and Mode IV from the cipher key CK and mixed initialization vector IVX is illustrated in figure 11 below.

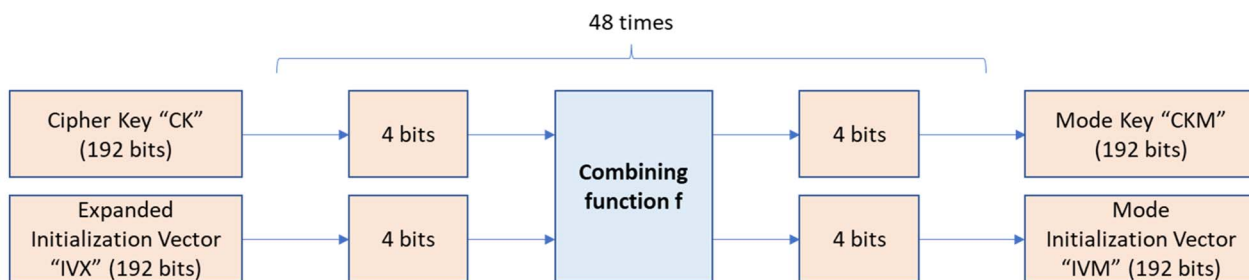

Figure 11: TEA7- Mode Key and Mode IV derivation

7.4 TEA7- Derivation of the Keystream Bits

The keystream bits KSS are obtained using Rijndael [i.1] with key length 192 bits and block size 256 bits, used in a counter mode. The key used is the Mode Key CKM, arranged into bytes $2^7\text{CKM}[8i] + 2^6\text{CKM}[8i+1] + \dots + \text{CKM}[8i+7]$ for $i = 0, \dots, 23$. The Rijndael algorithm is run in encryption mode to encrypt $\lceil \text{LENGTH}/256 \rceil$ successive plaintext blocks, where the notation $\lceil \text{LENGTH}/256 \rceil$ denotes the least integer \geq the floating-point quotient $\text{LENGTH}/256$. The plaintext for encryption j , for $j = 0, \dots, \lceil \text{LENGTH}/256 \rceil - 1$, is, informally, $\text{IVM} \parallel \text{'T', 'E', 'A', '7'} \parallel j$, where the byte values 'T', 'E', 'A', '7' code the name of the algorithm in ASCII, and j is coded as 4 bytes; more precisely, it is the 32-byte sequence p_0, \dots, p_{31} , where:

- $p_i = 2^7\text{IVM}[8i] + 2^6\text{IVM}[8i+1] + \dots + \text{IVM}[8i+7]$ for $i = 0, \dots, 23$;
- $p_{24} = 84, p_{25} = 69, p_{26} = 65, p_{27} = 55$ (those four values being in decimal);
- $2^{24}p_{28} + 2^{16}p_{29} + 2^8p_{30} + p_{31} = j$.

The keystream bit $\text{KSS}[i]$ is the bit $C_5[t]$, where:

- it is written as $i = 256r + 8s + t$, for $0 \leq s \leq 31$ and $0 \leq t \leq 7$;
- c_0, \dots, c_{31} are the ciphertext bytes obtained from the encryption where $j = r$;
- $c_s = 2^7C_s[0] + 2^6C_s[1] + \dots + C_s[7]$, for bits $C_s[0], \dots, C_s[7]$.

Note that if $(\text{LENGTH} \bmod 256) \leq 248$ then one or more higher numbered ciphertext bytes from the last block will be discarded. If $(\text{LENGTH} \bmod 8) > 0$ then one or more less significant bits from the last used ciphertext byte will be discarded.

Note that the maximum value of LENGTH, the number of bits of required keystream, is 8 288, according to the specification [i.2]. Since this maximum number of required keystream bits $\leq 2^{16}$, the 32-bit counter j can be implemented as an 8-bit counter with the other three bytes fixed to zero. If, in a future application, the maximum number of bits of required keystream is no more than 2^{24} bits, then the 32-bit counter can be implemented as a 16-bit counter with the other two bytes fixed to zero. If a full range of values for the 32-bit counter is implemented, keystream sequences of length up to 2^{40} can be generated.

The use of Rijndael in counter mode to produce keystream bits is shown in figure 12 below.

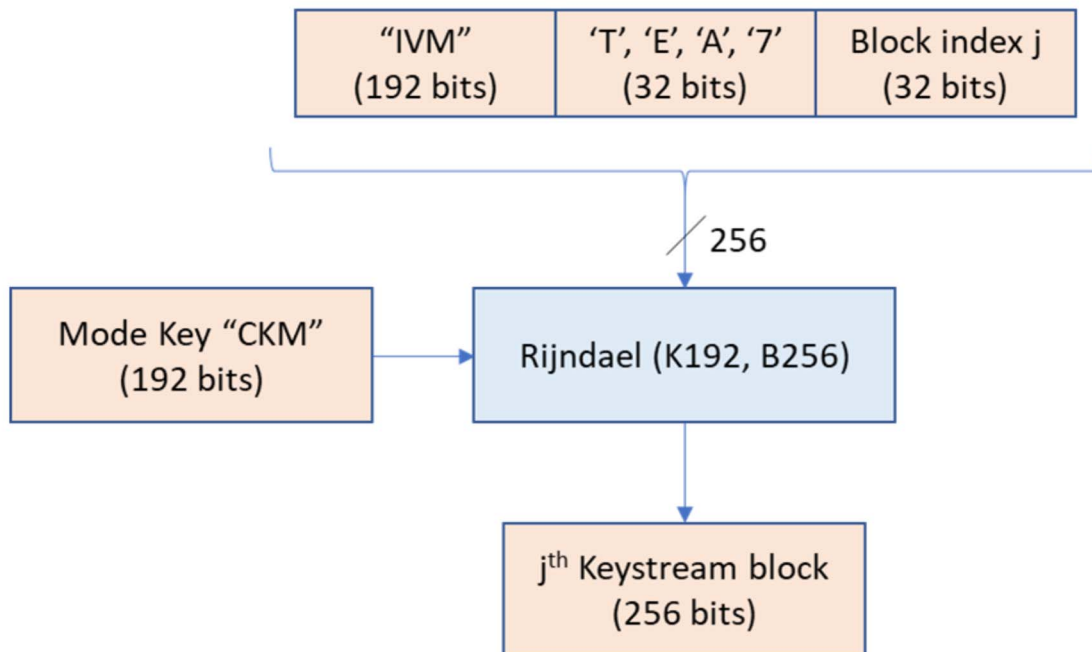

Figure 12: Keystream generation

7.5 TEA7 - Lookup Table for IV Mixing

Table 5 implements Galois Field multiplication by $z^7 + z^6 + z^4 + z^2 + z + 1$, as discussed in clause 7.2. Different rows correspond to different values of the most significant 4 bits of the input, and columns to the least significant 4 bits. For example, the value corresponding to 0x12 is found in the row labelled 0x1? and column labelled 0x?2, and is the byte value 0x6a.

Table 5

7.6 TEA7 - Definition of the Combining Function f

Table 6 defines the combining function f, which is used as defined in clause 7.3. Different rows correspond to different values of the most significant 4 bits of the input, and columns to the least significant 4 bits. For example, the value corresponding to 0x12 is found in the row labelled 0x1? and column labelled 0x?2, and is the byte value 0xc6.

Table 6

| | 0x?0 | 0x?1 | 0x?2 | 0x?3 | 0x?4 | 0x?5 | 0x?6 | 0x?7 | 0x?8 | 0x?9 | 0x?a | 0x?b | 0x?c | 0x?d | 0x?e | 0x?f |
|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0x0? | 0xe8 | 0xf8 | 0xc0 | 0x7a | 0x44 | 0x07 | 0x2b | 0x9e | 0x54 | 0x7e | 0x64 | 0x67 | 0xd5 | 0x8a | 0x38 | 0x04 |
