| NOTE 1: RFC 3428 [50] clause 7 states that all 2xx class responses to a MESSAGE request must not include any body, therefore for 2xx responses to the MESSAGE request the values on Sending side for "RFC status" and "Profile status" are "x", the values for Receiving side for "RFC status" and "Profile Status" are "n/a". RFC 3261 [26] subclause 7.4 states that all responses may contain bodies, therefore for all responses to the MESSAGE request other than 2xx responses, the values on Sending side for "RFC status" and "Profile status" are "o", the values for Receiving side for "RFC status" and "Profile Status" are "m". |   |

NOTE 1: No distinction has been made in these tables between first use of a request on a From/To/Call-ID combination, and the usage in a subsequent one. Therefore the use of "o" etc. above has been included from a viewpoint of first usage.

NOTE 2: The strength of this requirement in RFC 7315 [52] is SHOULD NOT, rather than MUST NOT.

NOTE 3: Support of this header in this method is dependent on the security mechanism and the security architecture which is implemented. Use of this header in this method is not appropriate to the security mechanism defined by 3GPP TS 33.203 [19].

Prerequisite A.5/12 - - OPTIONS request

| c46: | IF A.4/119 THEN m ELSE n/a - - Content-ID header field in Session Initiation Protocol (SIP).  |

NOTE 1: No distinction has been made in these tables between first use of a request on a From/To/Call-ID combination, and the usage in a subsequent one. Therefore the use of "o" etc. above has been included from a viewpoint of first usage.

NOTE 2: The strength of this requirement in RFC 7315 [52] is SHOULD NOT, rather than MUST NOT.

NOTE 3: Support of this header field in this method is dependent on the security mechanism and the security architecture which is implemented.

Prerequisite A.5/18 - - REGISTER request

**Table A.120: Supported message bodies within the REGISTER request**

## A.2.2 Proxy role

### A.2.2.1 Introduction

This subclause contains the ICS proforma tables related to the proxy role. They need to be completed only for proxy implementations.

Prerequisite: A.2/2 - - proxy role

## A.2.2.2 Major capabilities

**Table A.162: Major capabilities**

| Item | Does the implementation support   | Reference           | RFC status | Profile status |
|------|---|---------------------|------------|----------------|
|      | <b>Capabilities within main protocol</b>  |                     |            |                |
| 3    | initiate session release?   | [26] 16             | x          | c27            |
| 4    | stateless proxy behaviour?  | [26] 16.11          | o.1        | c29            |
| 5    | stateful proxy behaviour?   | [26] 16.2           | o.1        | c28            |
| 6    | forking of initial requests?  | [26] 16.1           | c1         | c31            |
| 7    | support of indication of TLS connections in the Record-Route header on the upstream side?                                       | [26] 16.7           | o          | n/a            |
| 8    | support of indication TLS connections in the Record-Route header on the downstream side?  | [26] 16.7           | o          | n/a            |
| 8A   | authentication between UA and proxy?  | [26] 20.28, 22.3    | o          | c85            |
| 9    | insertion of date in requests and responses?  | [26] 20.17          | o          | o              |
| 10   | suppression or modification of alerting information data?   | [26] 20.4           | o          | o              |
| 11   | reading the contents of the Require header before proxying the request or response?   | [26] 20.32          | o          | o              |
| 12   | adding or modifying the contents of the Require header before proxying the REGISTER request or response                         | [26] 20.32          | o          | m              |
| 13   | adding or modifying the contents of the Require header before proxying the request or response for methods other than REGISTER? | [26] 20.32          | o          | o              |
| 14   | being able to insert itself in the subsequent transactions in a dialog (record-routing)?  | [26] 16.6           | o          | c2             |
| 15   | the requirement to be able to use separate URIs in the upstream direction and downstream direction when record routing?         | [26] 16.7           | c3         | c3             |
| 16   | reading the contents of the Supported header before proxying the response?  | [26] 20.37          | o          | o              |
| 17   | reading the contents of the Unsupported header before proxying the 420 response to a REGISTER?                                  | [26] 20.40          | o          | m              |
| 18   | reading the contents of the Unsupported header before proxying the 420 response to a method other than REGISTER?                | [26] 20.40          | o          | o              |
| 19   | the inclusion of the Error-Info header in 3xx - 6xx responses?  | [26] 20.18          | o          | o              |
| 19A  | reading the contents of the Organization header before proxying the request or response?  | [26] 20.25          | o          | o              |
| 19B  | adding or concatenating the Organization header before proxying the request or response?  | [26] 20.25          | o          | o              |
| 19C  | reading the contents of the Call-Info header before proxying the request or response?   | [26] 20.9           | o          | o              |
| 19D  | adding or concatenating the Call-Info header before proxying the request or response?   | [26] 20.9           | o          | o              |
| 19E  | delete Contact headers from 3xx responses prior to relaying the response?   | [26] 20             | o          | o              |
| 19F  | proxy reading the contents of a body or including a body in a request or response?  | [26]                | o          | c88            |
| 19G  | proxy modifying the content of a body   | 3GPP TS 24.237 [8M] | n/a        | c103           |
|      | <b>Extensions</b>   |                     |            |                |

|     |  |           |      |      |
|-----|--|-----------|------|------|
| 20  | SIP INFO method and package framework?   | [25]      | o    | o    |
| 20A | legacy INFO usage?   | [25] 2, 3 | o    | o    |
| 21  | reliability of provisional responses in SIP?   | [27]      | o    | i    |
| 22  | the REFER method?  | [36]      | o    | o    |
| 22A | clarifications for the use of REFER with RFC6665?  | [231]     | c113 | c113 |
| 22B | explicit subscriptions for the REFER method?   | [232]     | o    | o    |
| 23  | integration of resource management and SIP?  | [30] [64] | o    | i    |
| 24  | the SIP UPDATE method?   | [29]      | c4   | i    |
| 26  | SIP extensions for media authorization?  | [31]      | o    | c7   |
| 27  | SIP specific event notification  | [28]      | o    | i    |
| 28  | a clarification on the use of GRUUs in the SIP event notification framework?   | [232]     | n/a  | n/a  |
| 29  | Session Initiation Protocol Extension Header Field for Registering Non-Adjacent Contacts   | [35]      | o    | c6   |
| 30  | private extensions to the Session Initiation Protocol (SIP) for asserted identity within trusted networks  | [34]      | o    | m    |
| 30A | act as first entity within the trust domain for asserted identity?   | [34]      | c5   | c9   |
| 30B | act as entity within trust network that can route outside the trust network?   | [34]      | c5   | c9   |
| 30C | act as entity passing on identity transparently independent of trust domain?   | [34]      | c5   | c96  |
| 31  | a privacy mechanism for the Session Initiation Protocol (SIP)  | [33]      | o    | m    |
| 31A | request of privacy by the inclusion of a Privacy header  | [33]      | n/a  | n/a  |
| 31B | application of privacy based on the received Privacy header  | [33]      | c10  | c12  |
| 31C | passing on of the Privacy header transparently   | [33]      | c10  | c13  |
| 31D | application of the privacy option "header" such that those headers which cannot be completely expunged of identifying information without the assistance of intermediaries are obscured? | [33] 5.1  | x    | x    |
| 31E | application of the privacy option "session" such that anonymization for the session(s) initiated by this message occurs?   | [33] 5.2  | n/a  | n/a  |
| 31F | application of the privacy option "user" such that user level privacy functions are provided by the network?   | [33] 5.3  | n/a  | n/a  |
| 31G | application of the privacy option "id" such that privacy of the network asserted identity is provided by the network?  | [34] 7    | c11  | c12  |
| 31H | application of the privacy option "history" such that privacy of the History-Info header is provided by the network?   | [66] 7.2  | c34  | c34  |
| 32  | Session Initiation Protocol Extension Header Field for Service Route Discovery During Registration   | [38]      | o    | c30  |
| 33  | a messaging mechanism for the Session Initiation Protocol (SIP)  | [50]      | o    | m    |
| 34  | Compressing the Session Initiation Protocol  | [55]      | o    | c7   |

| o.1:    | It is mandatory to support at least one of these items.  |
| o.2:    | It is mandatory to support at least one of these items.  |
| o.3:    | It is mandatory to support at least one of these items.  |
| o.4:    | At least one of these capabilities is supported.   |
| o.5:    | It is mandatory to support exactly one of these items.   |
| o.6:    | It is mandatory to support exactly one of these items.   |
| o.7:    | It is mandatory to support at least one of these items.  |
| o.8:    | It is mandatory to support at least one of these items.  |
| o.9:    | At least one of these capabilities is supported.   |
| NOTE 1: | An AS acting as a proxy may be outside the trust domain, and therefore not able to support the capability for that reason; in this case it is perfectly reasonable for the header to be passed on transparently, as specified in the PDU parts of the profile. |
| NOTE 2: | Not applicable over Gm reference point (UE – P-CSCF).  |
| NOTE 3: | AS performing a service number translation (e.g. Freephone)  |

## A.2.2.3 PDUs

## A.3 Profile definition for the Session Description Protocol as used in the present document

### A.3.1 Introduction

Void.

### A.3.2 User agent role

This subclause contains the ICS proforma tables related to the user agent role. They need to be completed only for UA implementations.

Prerequisite: A.2/1 -- user agent role

### A.3.2.1 Major capabilities

**Table A.317: Major capabilities**

| Item | Does the implementation support  | Reference | RFC status | Profile status |
|------|--|-----------|------------|----------------|
|      | <b>Capabilities within main protocol</b>   |           |            |                |
|      | <b>Extensions</b>  |           |            |                |
| 22   | integration of resource management and SIP?  | [30] [64] | o          | c14            |
| 23   | grouping of media lines?   | [53]      | c3         | c3             |
| 24   | mapping of media streams to resource reservation flows?  | [54]      | o          | c1             |
| 25   | SDP bandwidth modifiers for RTCP bandwidth?  | [56]      | o          | o (NOTE 1)     |
| 26   | TCP-based media transport in the session description protocol?   | [83]      | o          | c2             |
| 27   | interactive connectivity establishment?  | [99]      | o          | c4             |
| 28   | session description protocol format for binary floor control protocol streams?   | [108]     | o          | o              |
| 29   | extended RTP profile for real-time transport control protocol (RTCP)-based feedback (RTP/AVPF)?  | [135]     | o          | c5             |
| 30   | SDP capability negotiation?  | [137]     | o          | c6             |
| 31   | Session Description Protocol (SDP) extension for setting up audio media streams over circuit-switched bearers in the Public Switched Telephone Network (PSTN)? | [155]     | o          | c7             |
| 32   | miscellaneous capabilities negotiation in the Session Description Protocol (SDP)?  | [156]     | o          | c7             |
| 33   | transport independent bandwidth modifier for the Session Description Protocol?   | [152]     | o          | c8             |
| 34   | Secure Real-time Transport Protocol (SRTP)?  | [169]     | o          | c15            |
| 35   | MIKEY-TICKET?  | [170]     | o          | c10            |
| 36   | SDES?  | [168]     | o          | c9             |
| 37   | end-to-access-edge media security using SDES?  | 7.5.2     | n/a        | c16            |
| 37A  | end-to-access-edge media security for MSRP using TLS and certificate fingerprints?   | 7.5.2     | n/a        | c22            |
| 37B  | end-to-access-edge media security for BFCP using TLS and certificate fingerprints?   | 7.5.2     | n/a        | c23            |
| 37C  | end-to-access-edge media security for UDPTL using DTLS and certificate fingerprints?   | 7.5.2     | n/a        | c24            |
| 38   | SDP media capabilities negotiation?  | [172]     | o          | c12            |
| 39   | Transcoding Services Invocation in the Session Initiation Protocol (SIP) Using Third Party Call Control (3pcc)?  | [166]     | o          | c13            |
| 40   | Message Session Relay Protocol?  | [178]     | o          | c17            |
| 40A  | Connection establishment for media anchoring for the message session relay protocol?   | [214]     | o          | c26            |
| 41   | a SDP offer/answer mechanism to enable file transfer?  | [185]     | o          | o              |
| 42   | optimal media routing  | [11D]     | n/a        | c18            |
| 43   | ECN for RTP over UDP   | [188]     | o          | c19            |
| 44   | T.38 FAX?  | [202]     | n/a        | c20            |
| 45   | support for reduced-size RTCP?   | [204]     | o          | o              |
| 46   | RTCP extended reports?   | [205]     | o          | o              |
| 47   | maximum receive SDU size?  | [9B]      | o          | o              |
| 48   | the SDP content attribute?   | [206]     | o          | c21            |
| 49   | a general mechanism for RTP header extensions?   | [210]     | o          | o              |

|     |  |               |     |     |
|-----|--|---------------|-----|-----|
| 50  | negotiation of generic image attributes in the session description protocol (SDP)? | [211]         | o   | o   |
| 51  | connection-oriented media transport over the TLS protocol in the SDP?              | [241]         | o   | c25 |
| 52  | UDPTL over DTLS?   | [217]         | o   | c27 |
| 53  | telepresence?  | [7G]          | o   | o   |
| 54  | SCTP over DTLS?  | [219]         | o   | c28 |
| 55  | DTLS-SRTP?   | [222], [223]  | o   | c29 |

## Annex B (normative): IP-Connectivity Access Network specific concepts when using GPRS to access IM CN subsystem

### B.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is General Packet Radio Service (GPRS). The GPRS IP-CAN has a core network:

- with SGSN connected to GGSN providing a UE with a PDP context for the IM CN subsystem-related signalling and media; or
- with SGSN connected to S-GW and S-GW connected to P-GW providing the UE with a PDP context for the IM CN subsystem-related signalling and media.

NOTE: The UE is unaware of how the network provides the UE with a PDP context for the IM CN subsystem-related signalling and media.

The core network can be supported by GERAN and UTRAN radio access networks.

The present annex also defines procedures for invoking CS domain services.

---

### B.2 GPRS aspects when connected to the IM CN subsystem

#### B.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the core network to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause. Requirements for the core network in support of this communication are specified in 3GPP TS 29.061 [11], 3GPP TS 29.207 [12] and 3GPP TS 29.212 [13B].

When using the GPRS IP-CAN, each IP-CAN bearer is provided by a PDP context.

#### B.2.2 Procedures at the UE

##### B.2.2.1 PDP context activation and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall:

- a) if not attached for GPRS services yet, perform a GPRS attach procedure as specified in 3GPP TS 24.008 [8];
- b) ensure that a PDP context used for SIP signalling according to the APN and GGSN or P-GW selection criteria described in 3GPP TS 23.060 [4] and 3GPP TS 27.060 [10A] is available. This PDP context shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration. As a result, the PDP context provides the UE with information that makes the UE able to construct an IPv4 or an IPv6 address;

NOTE 1: During the PDP context activation procedure, the UE and the core network negotiate whether the UE or the GPRS IP-CAN is responsible for the resource reservation applicable to all PDP contexts within the activated PDP address/APN pair, as described in 3GPP TS 24.008 [8].

When the bearer establishment is controlled by the UE, the UE shall choose one of the following options when performing establishment of this PDP context:

I. A dedicated PDP context for SIP signalling:

The UE shall indicate to the core network that this is a PDP context intended to carry IM CN subsystem-related signalling only by setting the IM CN Subsystem Signalling Flag. The UE may also use this PDP context for DNS and DHCP signalling according to the static packet filters as described in 3GPP TS 29.061 [11]. The UE can also set the Signalling Indication attribute within the QoS information element;

II. A general-purpose PDP context:

The UE may decide to use a general-purpose PDP Context to carry IM CN subsystem-related signalling. The UE shall indicate to the core network that this is a general-purpose PDP context by not setting the IM CN Subsystem Signalling Flag. The UE may carry both signalling and media on the general-purpose PDP context. The UE can also set the Signalling Indication attribute within the QoS information element.

NOTE 2: When the bearer establishment is controlled by the GPRS IP-CAN, the core network follows the procedures described in 3GPP TS 29.061 [11] in order to establish a dedicated PDP context for SIP signalling.

The UE indicates the IM CN Subsystem Signalling Flag within the Protocol Configuration Options information element of the ACTIVATE PDP CONTEXT REQUEST message or ACTIVATE SECONDARY PDP CONTEXT REQUEST message. Upon successful signalling PDP context establishment the UE receives an indication in the form of IM CN Subsystem Signalling Flag within the Protocol Configuration Options information element. If the flag is not received, the UE shall consider the PDP context as a general-purpose PDP context.

The encoding of the IM CN Subsystem Signalling Flag within the Protocol Configuration Options information element is described in 3GPP TS 24.008 [8].

The UE can indicate a request for prioritised handling over the radio interface by setting the Signalling Indication attribute (see 3GPP TS 23.107 [4A]). The general QoS negotiation mechanism and the encoding of the Signalling Indication attribute within the QoS information element are described in 3GPP TS 24.008 [8]; and

NOTE 3: A general-purpose PDP Context can carry both IM CN subsystem signalling and media, in case the media does not need to be authorized by Policy and Charging control mechanisms as defined in 3GPP TS 29.212 [13B] and Service Based Local Policy mechanisms defined in 3GPP TS 29.207 [12] and the media stream is not mandated by the P-CSCF to be carried in a separate PDP Context.

c) acquire a P-CSCF address(es).

The methods for P-CSCF discovery are:

I. When using IPv4, employ the Dynamic Host Configuration Protocol (DHCP) RFC 2132 [20F], the DHCPv4 options for SIP servers RFC 3361 [35A], and RFC 3263 [27A] as described in subclause 9.2.1. When using IPv6, employ Dynamic Host Configuration Protocol for IPv6 (DHCPv6) RFC 3315 [40], the DHCPv6 options for SIP servers RFC 3319 [41] and DHCPv6 options for Domain Name Servers (DNS) RFC 3646 [56C] as described in subclause 9.2.1.

II. Transfer P-CSCF address(es) within the PDP context activation procedure.

The UE shall indicate the request for a P-CSCF address within the Protocol Configuration Options information element of the ACTIVATE PDP CONTEXT REQUEST message or ACTIVATE SECONDARY PDP CONTEXT REQUEST message.

If the UE is provided with a list of P-CSCF IPv4 or IPv6 addresses in the ACTIVATE PDP CONTEXT ACCEPT message or ACTIVATE SECONDARY PDP CONTEXT ACCEPT message, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the highest preference and the last P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the lowest preference.

III. The UE selects a P-CSCF from the list (see 3GPP TS 31.103 [15B]) stored in the ISIM.

IV. The UE selects a P-CSCF from the list in IMS management object.

The UE shall use method IV to select a P-CSCF, if:

- a P-CSCF is to be discovered in the home network;
- the UE is roaming; and
- the IMS management object contains the P-CSCF list.

The UE shall use method III to select the P-CSCF, if:

- a P-CSCF is to be discovered in the home network;
- the UE is roaming;
- either the UE does not contain the IMS management object, or the UE contains the IMS management object, but the IMS management object does not contain the P-CSCF list; and
- the ISIM residing in the UICC supports the P-CSCF list.

The UE can freely select method I or II for P-CSCF discovery, if:

- the UE is in the home network; or
- the UE is roaming and the P-CSCF is to be discovered in the visited network.

The UE can select method IV, if:

- the UE is in the home network; and
- the IMS management object contains the P-CSCF list.

In case method I is selected and several P-CSCF addresses or FQDNs are provided to the UE, the selection of P-CSCF address or FQDN shall be performed as indicated in RFC 3361 [35A] when using IPv4 or RFC 3319 [41] when using IPv6. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the UE is implementation specific.

NOTE 4: The UE decides whether the P-CSCF is to be discovered in the serving network or in the home network based on local configuration, e.g. whether the application on the UE is permitted to use local breakout.

If the UE is designed to use I above, but receives P-CSCF address(es) according to II, then the UE shall either ignore the received address(es), or use the address(es) in accordance with II, and not proceed with the DHCP request according to I.

If the UE is configured to use Option II above and detects that all P-CSCFs known by the UE have been used when the UE selects a different P-CSCF as a result of:

- receiving 305 (Use Proxy) to the REGISTER request;
- receiving 504 (Server Time-out); or
- expiration of the timer F at the UE,

then the UE should:

- release IP-CAN bearer that is used only for the transport of SIP signalling and that are not used for other non-IMS applications, except emergency IP-CAN bearers;
- perform a new P-CSCF discovery procedure as described in subclause 9.2.1; and
- perform the procedures for initial registration as described in subclause 5.1.1.2.

NOTE 5: The UE may not be able to release the IP-CAN bearer if the IP-CAN bearer is in use by other applications.

When using IPv4, the UE may request a DNS Server IPv4 address(es) via RFC 2132 [20F] or by the Protocol Configuration Options information element when activating a PDP context according to 3GPP TS 27.060 [10A].

When using IPv6, the UE may request a DNS Server IPv6 address(es) via RFC 3315 [40] and RFC 3646 [56C] or by the Protocol Configuration Options information element when activating a PDP context according to 3GPP TS 27.060 [10A].

The encoding of the request and response for IPv4 or IPv6 address(es) for DNS server(s) and list of P-CSCF address(es) within the Protocol Configuration Options information element is described in 3GPP TS 24.008 [8].

When:

- the UE obtains a PDP context used for SIP signalling by performing handover of the connection from another IP-CAN;
- the IP address of the UE is not changed during the handover; and
- the UE already communicates with the IM CN subsystem via the connection with the other IP-CAN, e.g. the UE determines that its contact with host portion set to the UE IP address (or FQDN of the UE) associated with the connection with the other IP-CAN has been bound to a public user identity;

the UE shall continue using the P-CSCF address(es) acquired in the other IP-CAN.

### B.2.2.1A Modification of a PDP context used for SIP signalling

The PDP context shall not be modified from a dedicated PDP context for SIP signalling to a general-purpose PDP context or vice versa. The IM CN Subsystem Signalling Flag shall not be set in the Protocol Configuration Options information element of the MODIFY PDP CONTEXT REQUEST message.

The UE shall not indicate the request for a P-CSCF address within the Protocol Configuration Options information element of the MODIFY PDP CONTEXT REQUEST message. The UE shall ignore P-CSCF address(es) if received in the Protocol Configuration Options information element of the MODIFY PDP CONTEXT RESPONSE message.

### B.2.2.1B Re-establishment of the PDP context for SIP signalling

If the UE registered a public user identity with an IP address allocated for the APN of the PDP context used for SIP signalling, the PDP context used for SIP signalling is deactivated as result of signalling from the core network (e.g. no longer available as a result of a successful GPRS routeing area update procedure) and:

- i) if the signalling from the core network results in requiring the UE to initiate activation of the PDP context used for SIP signalling; or
- ii) if the UE needs to continue having a public user identity registered with an IP address allocated for the APN;

and the UE is allowed to send:

- ACTIVATE PDP CONTEXT REQUEST message; or
- ACTIVATE SECONDARY PDP CONTEXT REQUEST message,

to activate the PDP context for SIP signalling, the UE shall:

- A) if the non-access stratum is performing the PDP context activation procedure for the APN triggered as result of the signalling from the core network, wait until the PDP context activation procedure for the APN finishes; and
- B) perform the procedures in subclause B.2.2.1, bullets a), b) and c).

If:

- none of the bullets i) and ii) of this subclause evaluate to true;
- the UE is not allowed to send the ACTIVATE (SECONDARY) PDP CONTEXT REQUEST message;
- the procedures in bullet B) of this subclause were unable to ensure that the PDP context used for SIP signalling is available; or
- the procedures in bullet B) of this subclause were unable to acquire any P-CSCF address(es);

and if the PDP context used for SIP signalling was a dedicated PDP context for SIP signalling as described in subclause B.2.2.1, the UE shall deactivate all PDP contexts established as a result of SIP signalling according to the 3GPP TS 24.008 [8].

NOTE: 3GPP TS 24.008 [8] specifies conditions that prevent the UE from sending an ACTIVATE (SECONDARY) PDP CONTEXT REQUEST message.

If all PDP contexts for the APN were deactivated at the start of this subclause and the procedures in bullet B) of this subclause ensured that the PDP context used for SIP signalling is available and acquired the P-CSCF address(es), the UE shall perform a new initial registration according to subclause 5.1.1.2.

### B.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure performs one of the following procedures:

- A. if the UE used method II for P-CSCF discovery and if the UE receives one or more P-CSCF address(es) in the Protocol Configuration Options information element of a MODIFY PDP CONTEXT REQUEST message and the one or more P-CSCF address(es) do not include the address of the currently used P-CSCF, then the UE shall acquire a different P-CSCF address from the one or more P-CSCF address(es) in the MODIFY PDP CONTEXT REQUEST message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority.

If the UE used method II for P-CSCF discovery and if the UE has previously sent the "P-CSCF Re-selection support" PCO indicator at PDP Context Activation and if the UE receives one or more P-CSCF address(es) in the Protocol Configuration Options information element of a MODIFY PDP CONTEXT REQUEST message, then the UE shall acquire a P-CSCF address from the one or more P-CSCF address(es) in the MODIFY PDP CONTEXT REQUEST message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority;

- B. if the UE uses RFC 6223 [143] as part of P-CSCF restoration procedures, and if the P-CSCF fails to respond to a keep-alive request, then the UE shall acquire a different P-CSCF address using one of the methods I, III and IV for P-CSCF discovery described in the subclause B.2.2.1.

If the UE has an ongoing session and acquired the new P-CSCF address by using procedure A described above, the UE may wait until the UE has detected that the ongoing session has ended before performing an initial registration as specified in subclause 5.1.

In all other cases, when the UE has acquired the P-CSCF address, the UE not having an ongoing session shall perform an initial registration as specified in subclause 5.1.

NOTE 1: For UEs using procedure A described above, the network ensures that P-CSCF address(es) in the Protocol Configuration Options information element of a MODIFY PDP CONTEXT REQUEST is sent only during P-CSCF restoration procedures as defined in subclause 5 of 3GPP TS 23.380 [7D].

NOTE 2: The P-CSCF can be completely unreachable, so it is up to UE implementation to detect the end of an ongoing session, e.g. using media plane inactivity detection. Services depending on signalling such as CW and MT calls will not work during this time.

### B.2.2.2 Session management procedures

The existing procedures for session management as described in 3GPP TS 24.008 [8] shall apply while the UE is connected to the IM CN subsystem.

### B.2.2.3 Mobility management procedures

The existing procedures for mobility management as described in 3GPP TS 24.008 [8] shall apply while the UE is connected to the IM CN subsystem.

### B.2.2.4 Cell selection and lack of coverage

The existing mechanisms and criteria for cell selection as described in 3GPP TS 25.304 [9] and 3GPP TS 44.018 [20] shall apply while the UE is connected to the IM CN subsystem.

### B.2.2.5 PDP contexts for media

#### B.2.2.5.1 General requirements

The UE can establish media streams that belong to different SIP sessions on the same PDP context.

During establishment of a session, the UE establishes data stream(s) for media related to the session. Such data stream(s) may result in activation of additional PDP context(s). Such additional PDP context(s) shall be established as secondary PDP contexts associated to the PDP context used for signalling. Such secondary PDP contexts for media can be established either by the UE or the core network.

If the bearer establishment is controlled by the UE, the UE starts reserving its local resources whenever it has sufficient information about the media streams, media authorization and used codecs available as specified in 3GPP TS 24.008 [8].

NOTE 1: If the bearer establishment is controlled by the GPRS IP-CAN, the resource reservation requests are initiated by the core network after the P-CSCF has authorised the respective IP flows and provided the QoS requirements over the Rx interface to the PCRF, as described in 3GPP TS 29.214 [13D].

NOTE 2: When the UE has to allocate bandwidth for RTP and RTCP in a PDP context, the UE uses the rules as those outlined in 3GPP TS 29.213 [13C].

#### B.2.2.5.1A Activation or modification of PDP contexts for media by the UE

If the UE is configured not to initiate resource allocation for media according to 3GPP TS 24.167 [8G] and both UE and the core network are allowed to establish the secondary PDP contents, then the UE shall refrain from establishing the secondary PDP context(s) for media and from modifying existing PDP contexts for media until the UE considers that the network did not initiate resource allocation for the media.

If the UE receives indication within the SDP according to RFC 3524 [54] that media stream(s) belong to group(s), the media stream(s) shall be set up on separate PDP contexts according to the indication of grouping of media streams. The UE may freely group media streams to PDP context(s) in case no indication of grouping of media streams is received from the P-CSCF.

If the capabilities of the originating UE prevents it from establishment of additional PDP contexts according to the media grouping attributes given by the P-CSCF in accordance with RFC 3524 [54], the UE will not establish such grouping of media streams. Instead, the originating UE shall negotiate media parameters for the session according to RFC 3264 [27B].

If the capabilities of the terminating UE prevents it from establishment of additional PDP contexts according to the media grouping attributes given by the P-CSCF in accordance with RFC 3524 [54], the UE will not establish such grouping of media streams. Instead, the terminating UE shall the UE shall handle such SDP offers in accordance with RFC 3388 [53].

The UE can receive a media authorization token in the P-Media-Authorization header field from the P-CSCF according to RFC 3313 [31]. If a media authorization token is received in the P-Media-Authorization header field when a SIP session is initiated, the UE shall:

- either use existing PDP context(s) where another media authorization token is already in use and no indication of grouping of media streams is required; or
- establish separate PDP context(s) for the media; or

- use an existing PDP context where media authorization token is not in use and no indication of grouping of media streams is required.

When a UE modifies a PDP context to indicate a new media authorization token:

- either as a result of establishment of an additional SIP session; or
- modification of media streams for an ongoing SIP session;

the UE shall include all media authorization tokens and all flow identifiers for all ongoing SIP sessions that use this particular PDP context.

If a media authorization token is received in subsequent messages for the same SIP session, the UE shall:

- use the existing PDP context(s) for media;
- modify the existing PDP context(s) for media; or
- establish additional PDP context(s) for media.

If either background or interactive QoS class is needed for the media, then the UE does not need to use the authorization token even if it receives one. In this case the UE may reuse an existing PDP context and it does not need to request PDP context modification unless it needs to modify the QoS.

If existing PDP context(s) where another media authorization token is already in use is re-used for the media, or separate PDP context(s) is established for the media, the UE shall proceed as follows:

- when a SIP session is terminated, the media authorization token is no longer valid and the UE shall not include it in future GPRS session management messages. The UE shall send a MODIFY PDP CONTEXT REQUEST message updating the binding information by deleting the media authorization token and the corresponding flow identifiers that are no longer valid. If a SIP session is terminated and no other SIP sessions are using the PDP context, the UE shall either update the binding information as described above or deactivate the PDP context;
- the UE shall transparently pass the media authorization token received from the P-CSCF in a response to an INVITE request at originating setup or in the INVITE request at terminating setup to the core network. The UE shall signal it by inserting it within the Traffic Flow Template information element in the ACTIVATE SECONDARY PDP CONTEXT REQUEST message or the MODIFY PDP CONTEXT REQUEST message;
- to identify to the core network which flow(s) (identified by m-lines within the SDP) that are transferred within a particular PDP context, the UE shall set the flow identifier(s) within the Traffic Flow Template information element in the ACTIVATE SECONDARY PDP CONTEXT REQUEST message or the MODIFY PDP CONTEXT REQUEST message. Detailed description of how the flow identifiers are constructed is provided in 3GPP TS 29.207 [12];
- if the UE receives several media authorization tokens from the P-CSCF within the same SIP request or response, the first instance of the media authorization token shall be sent to the core network, and subsequent instances are discarded by the UE; and
- the UE shall not include the IM CN Subsystem Signalling Flag when a PDP context for media is established or modified.

The encoding of the media authorization token and the flow identifiers within the Traffic Flow Template information element is described in 3GPP TS 24.008 [8].

#### B.2.2.5.1B Activation or modification of PDP contexts for media by the core network

If the UE receives an activation request for a PDP context which is associated with the PDP context used for signalling, the UE shall, based on the information contained in the Traffic Flow Template information element, correlate the media PDP context with a currently ongoing SIP session establishment or SIP session modification.

If the UE receives a modification request for a PDP context that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) modify the related PDP context in accordance with the received modification request.

### B.2.2.5.1C Deactivation of PDP context for media

When a data stream for media related to a session is released, if the PDP context transporting the data stream is no longer needed and if the PDP context has been activated by the UE, then the UE deactivates the PDP context.

NOTE: The PDP context can be needed e.g. for other data streams of a session or for other applications in the UE.

### B.2.2.5.2 Special requirements applying to forked responses

NOTE 1: The procedures in this subclause only apply when the UE requests activation and modification of media bearers. In the case where the core network activates and modifies the media bearers the network takes care of the handling of media bearers in the case of forking.

Since the UE does not know that forking has occurred until a second, provisional response arrives, the UE sets up the PDP context(s) as required by the initial response received. If a subsequent provisional response is received, different alternative actions may be performed depending on the requirements in the SDP answer:

- 1) the bearer requirements of the subsequent SDP can be accommodated by the existing PDP context(s). The UE performs no activation or modification of PDP contexts.
- 2) the subsequent SDP introduces different QoS requirements or additional IP flows. The UE modifies the existing PDP context(s), if necessary, according to subclause B.2.2.5.1A.
- 3) the subsequent SDP introduces one or more additional IP flows. The UE establishes additional PDP context(s) according to subclause B.2.2.5.1A.

NOTE 2: When several forked responses are received, the resources requested by the UE is are the "logical OR" of the resources indicated in the multiple responses to avoid allocation of unnecessary resources. The UE does not request more resources than proposed in the original INVITE request.

NOTE 3: When service-based local policy is applied, the UE receives the same authorization token for all forked requests/responses related to the same SIP session.

When a final answer is received for one of the early dialogs, the UE proceeds to set up the SIP session. The UE shall release all the unneeded radio/bearer resources. Therefore, upon the reception of the first final 200 (OK) response for the INVITE request (in addition to the procedures defined in RFC 3261 [26] subclause 13.2.2.4), the UE shall:

- 1) in case PDP context(s) were established or modified as a consequence of the INVITE request and forked provisional responses that are not related to the accepted 200 (OK) response, delete the PDP context(s) or modify the delete the PDP context(s) back to their original state.

### B.2.2.5.3 Unsuccessful situations

One of the Go, Gq, Rx and Gx interface related error codes can be received by the UE in the ACTIVATE SECONDARY PDP CONTEXT REJECT message or the MODIFY PDP CONTEXT REJECT message. If the UE receives a Go, Gq, Rx and Gx interface related error code, the UE shall either handle the resource reservation failure as described in subclause 6.1.1 or retransmit the message up to three times. The Go, Gq, Rx and Gx interface related error codes are further specified in 3GPP TS 29.207 [12], 3GPP TS 29.209 [13A], 3GPP TS 29.214 [13D] and 3GPP TS 29.212 [13B].

## B.2.2.6 Emergency service

### B.2.2.6.1 General

Emergency bearers are defined for use in emergency calls in GPRS IP-CAN and core network support of these bearers is indicated to the UE in NAS signalling. Where the UE recognises that a call request is an emergency call and the core network supports emergency bearers, the UE shall use these bearers for both signalling and media on emergency calls made using the IM CN subsystem.

Some jurisdictions allow emergency calls to be made when the UE does not contain an ISIM or USIM, or where the credentials are not accepted. Additionally, where the UE is in state GMM-REGISTERED.LIMITED-SERVICE and GMM-REGISTERED.PLMN-SEARCH, a normal ATTACH has been attempted but it can also be assumed that a

registration in the IM CN subsystem will also fail. In such cases, subject to the lower layers indicating that the network does support emergency bearer services in limited service state (see 3GPP TS 25.331 [9A]), the procedures for emergency calls without registration can be applied, as defined in subclause 5.1.6.8.2. If the GPRS authentication procedure has already succeeded during the latest normal or emergency ATTACH procedure, the UE shall perform an initial emergency registration, as described in subclause 5.1.6.2 before attempting an emergency call as described in subclause 5.1.6.8.3.

NOTE 1: The UE can determine that GPRS authentication procedure has succeeded during the emergency ATTACH procedure when an integrity protection algorithm is received in the RRC signalling SECURITY MODE COMMAND message (see 3GPP TS 25.331 [9A]).

When activating a PDP context to perform emergency registration, the UE shall request a PDP context for emergency bearer services as defined in 3GPP TS 24.008 [8]. The procedures for PDP context activation and P-CSCF discovery, as described in subclause B.2.2.1 of this specification apply accordingly.

In order to find out whether the UE is attached to the home PLMN or to the visited PLMN, the UE shall compare the MCC and MNC values derived from its IMSI with the MCC and MNC of the PLMN the UE is attached to. If the MCC and MNC of the PLMN the UE is attached to do not match with the MCC and MNC derived from the IMSI, then for the purpose of emergency calls in the IM CN subsystem the UE shall consider to be attached to a VPLMN.

NOTE 2: In this respect an equivalent HPLMN, as defined in 3GPP TS 23.122 [4C] will be considered as a visited network.

If the dialled number is equal to an emergency number stored in the ME, in the USIM or in the Local Emergency Number List (as defined in 3GPP TS 24.008 [8]), then the UE shall recognize a number as for an emergency call and performs the procedures in subclause B.2.2.6.1A.

NOTE 3: The Extended Local Emergency Numbers List (see 3GPP TS 24.301 [8J]) does not apply in this IP-CAN.

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, if:

- the 380 (Alternate Service) response contains a Contact header field;
- the value of the Contact header field is a service URN; and
- the service URN has a top-level service type of "sos";

then the UE determines that "emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.3.1 if the 380 (Alternate Service) response does not contain a Contact header field with service URN that has a top-level service type of "sos", then the UE determines that "no emergency service information is included" as described 3GPP TS 23.167 [4B].

If the "emergency service information is included" as described 3GPP TS 23.167 [4B]:

- 1) if the URN in the Contact header field matches an emergency service URN in table B.2.2.6.1, then the type of emergency service is the value corresponding to the matching entry in table B.2.2.6.1; and
- 2) if the URN in the Contact header field does not match any emergency service URN in table B.2.2.6.1, then the type of emergency service is not identified.

NOTE 4: In bullet 2), the URN in the Contact header field either contains "no emergency subservice type" as described in 3GPP TS 23.167 [4B] triggering an emergency call, or contains an "emergency subservice type that does not map into an emergency service category for the CS domain" as described in 3GPP TS 23.167 [4B] triggering a normal call when the dialled number is available or triggering an emergency call when the dialled number is not available. The country specific URN is an example of a "emergency subservice type that does not map into an emergency service category for the CS domain".

When the emergency registration expires, the UE should disconnect the PDP context for emergency bearer services as defined in 3GPP TS 24.008 [8].

Upon receiving a 3xx other than 380 (Alternative service), 4xx, 5xx or 6xx response to an INVITE request for a UE detectable emergency call, the UE shall perform domain selection as specified in 3GPP TS 23.167 [4B] annex H, to re-attempt the emergency call.

### B.2.2.6.1A Type of emergency service derived from emergency service category value

The type of emergency service for an emergency number is derived from the settings of the emergency service category value (bits 1 to 5 of the emergency service category value as specified in subclause 10.5.4.33 of 3GPP TS 24.008 [8]). Table B.2.2.6.1 below specifies mappings between a type of emergency service and an emergency service URN. The UE shall use the mapping to match an emergency service URN and a type of emergency service. If a dialled number is an emergency number but does not map to a type of emergency service the service URN shall be "urn:service:sos".

**Table B.2.2.6.1: Mapping between type of emergency service and emergency service URN**

| Type of emergency service | Emergency service URN     |
|---------------------------|---------------------------|
| Police                    | urn:service:sos.police    |
| Ambulance                 | urn:service:sos.ambulance |
| Fire Brigade              | urn:service:sos.fire      |
| Marine Guard              | urn:service:sos.marine    |
| Mountain Rescue           | urn:service:sos.mountain  |

NOTE 1: It is not possible for a UE to indicate more than one type of emergency service in an emergency service URN.

If an IP-CAN, capable of providing local emergency numbers, did not provide a local emergency number that matches the dialled number (see subclause 5.1.6.1) and multiple types of emergency service can be derived for a dialled number from the information configured on the USIM then:

- if the UE is in the HPLMN, the UE shall map any one of these types of emergency service to an emergency service URN as specified in table B.2.2.6.1; and
- if the UE is in the VPLMN, the UE shall select "urn:service:sos".

NOTE 2: If the Non-3GPP emergency number indicator within the Non-3GPP NW provided policies IE (see 3GPP TS 24.008 [8]) provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers permitted", the UE also considers WLAN provided local emergency numbers (see 3GPP TS 24.302 [8U], subclause 4.7). If the Non-3GPP NW provided policies IE provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers not permitted", the UE does not consider WLAN provided local emergency numbers. If the Non-3GPP NW provided policies IE is not provided through registration procedures over 3GPP access, the UE does not consider WLAN provided local emergency numbers.

If an IP-CAN, capable of providing local emergency numbers, provided a local emergency number that matches the dialled number (see subclause 5.1.6.1), and:

- if the UE can derive one or more types of emergency service from the information received from the IP-CAN for the dialled number and the UE cannot derive types of emergency service from the information configured on the USIM for the dialled number; or
- if the UE is able to derive identical types of emergency service from both the information received from the IP-CAN for the dialled number and from the information configured on the USIM for the dialled number,

then the UE shall map any one of these emergency service types to an emergency service URN as specified in table B.2.2.6.1.

NOTE 3: How the UE resolves clashes where an emergency number is associated with one or more different types of emergency service configured in the USIM and in information received from the core network, is implementation dependent.

### B.2.2.6.1B Type of emergency service derived from extended local emergency number list

Void

### B.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

### B.2.2.6.3 Current location discovery during an emergency call

Void.

---

## B.2A Usage of SDP

### B.2A.0 General

NOTE: When:

- establishing a session which is not an emergency session; or
- modifying a session which is not an emergency session;

and if the IMSVoPS indicator is received in the "Network feature support" Information Element (see 3GPP TS 24.008 [8]), the UE constructs SDP based on the restrictions indicated in the IMSVoPS indicator. Regardless whether the IMSVoPS indicator indicating voice is supported or not, m-lines can be set to "audio" and exclude voice codecs from the SDP answer or SDP offer.

### B.2A.1 Impact on SDP offer / answer of activation or modification of PDP contexts for media by the core network

If due to the activation of PDP context from the core network the related SDP media description needs to be changed the UE shall update the related SDP information by sending, within a SIP request, a new SDP offer for each of the existing SIP dialogs,

If the UE receives a modification request from the core network for a PDP context that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) if, due to the modification of the PDP context, the related SDP media description need to be changed, update the related SDP information by sending, with in a SIP request, a new SDP offer for each of the existing SIP dialogs , and respond to the PDP context modification request.

NOTE: The UE can decide to indicate additional media streams as well as additional or different codecs in the SDP offer than those used in the already ongoing session.

### B.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

If the UE receives an SDP offer where the SDP offer includes all media streams for which the originating side indicated its local preconditions as met, if the precondition mechanism is supported by the terminating UE and the IP-CAN performs network-initiated resource reservation for the terminating UE and the available resources are not sufficient for the received offer the terminating UE shall indicate its local preconditions and provide the SDP answer to the originating side without waiting for resource reservation.

NOTE 1: If the resource reservation is controlled by the GPRS IP-CAN, the resource reservation request is initiated by the core network after the P-CSCF has authorised the respective IP flows and provided the QoS requirements over the Rx interface to the PCRF as described in 3GPP TS 29.214 [13D].

NOTE 2: During the PDP context activation procedure the UE and the core network negotiate whether the UE or the GPRS IP-CAN is responsible for the resource reservation applicable to all PDP contexts within the activated PDP address/APN pair as described in 3GPP TS 24.008 [8].

## B.2A.3 Emergency service

NOTE: When establishing an emergency session or when modifying an emergency session, the IMSVoPS indicator does not influence handling of SDP offer and SDP answer.

---

## B.3 Application usage of SIP

### B.3.1 Procedures at the UE

#### B.3.1.0 Registration and authentication

The UE shall perform reregistration of a previously registered public user identity bound to any one of its contact addresses when changing to an IP-CAN for which usage is specified in annex R. The reregistration is performed using the new IP-CAN.

NOTE 1: This document does not specify how the UE detects that the used IP-CAN has changed. The information that is forcing the reregistration is also used to generate the content for the P-Access-Network-Info header field.

NOTE 2: The UE will send the reregistration irrespective of whether it has a SIP dialog or not.

If the UE supports the 3GPP PS data off, then the UE shall in all REGISTER requests include the "+g.3gpp.ps-data-off" header field parameter defined in subclause 7.9.8 set to a value indicating the 3GPP PS data off status.

When the UE sends a REGISTER request, if the 3GPP PS data off status is "active", then the UE shall only include media feature tags associated with services that are 3GPP PS data off exempt services in the g.3gpp.icsi-ref media feature tag, as defined in subclause 7.9.2 and RFC 3840 [62], for the IMS communication services it intends to use.

If the UE is registered, and the 3GPP PS data off status is changed or the UE is provided by the network with a new list of 3GPP PS data off exempt services while the 3GPP PS data off status is "active", then the UE shall perform a reregistration of the previously registered public user identity.

#### B.3.1.0a IMS\_Registration\_handling policy

The IMS\_Registration\_handling policy indicates whether the UE deregisters from IMS after a configured amount of time after receiving an indication that the IMS Voice over PS Session is not supported.

The UE may support the IMS\_Registration\_handling policy.

If the UE supports the IMS\_Registration\_handling policy, the UE may support being configured with the IMS\_Registration\_handling policy using one or more of the following methods:

- a) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G].

If the UE is configured with both the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G] and the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file shall take precedence.

NOTE 1: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

If the UE is registered with IMS and the IMSVoPS indicator, provided by the lower layers (see 3GPP TS 24.301 [8J]), indicates voice is not supported, the UE shall:

- A) if the `Stay_Registered_When_VoPS_Not_Supported` leaf indicates requirement to stay registered, the UE needs not to deregister and maintains the registration as required for IMS services; or

NOTE 2: The UE will periodically refresh the registration when needed.

- B) if the `Stay_Registered_When_VoPS_Not_Supported` leaf indicates requirement to deregister and the `Deregistration_Timer` leaf used to configure the NoVoPS-dereg timer defined in table 7.8.1 contains a timer value for the time to wait before deregistering from IMS, start a timer with the value indicated in the policy and:

- a) if the timer expires before the UE receives an indication from the lower layers that IMS voice is supported:
- 1) if there is no ongoing IMS session, either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of the IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6; or
  - 2) if there is ongoing IMS session, and
    - i) if the UE does not receive indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6 as soon as the ongoing IMS based service is terminated ; or
    - ii) if the UE receives indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, cancel the timer; or

NOTE 3: How the UE selects reregistration or deregistration is implementation dependent (e.g., SMS service)

- b) if the UE receives an indication from the lower layers that IMS voice is supported before the timer expires, cancel the timer.

If the `IMS_Registration_handling` policy is not configured, the UE behaviour is implementation specific.

### B.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

#### B.3.1.1A Cellular-Network-Info header field

Not applicable.

### B.3.1.2 Availability for calls

The UE indicates to the non-access stratum the status of being available for voice over PS when:

- 1) the UE is capable of receiving any (but not necessarily all) of the media types which the CS domain supports, such that the media type can also be used when accessing the IM CN subsystem using the current IP-CAN;
- 2) if the media type of item 1 is an "audio" media type, the UE supports codecs suitable for (conversational) speech, the "audio" media type is not restricted from inclusion in an SDP message according to the media type restriction policy as specified in subclause 6.1.1, and:
  - a) 3GPP PS data off status is "inactive";
  - b) 3GPP PS data off status is "active", the UE is in the HPLMN or the EHPLMN, and MMTEL voice is a 3GPP PS data off exempt service; or
  - c) 3GPP PS data off status is "active", the UE is in the VPLMN, the UE is configured with an indication that MMTEL voice is a 3GPP PS data off exempt service in a VPLMN, and MMTEL voice is a 3GPP PS data off roaming exempt service; and

- 3) the UE determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media.

The UE indicates to the non-access stratum the status of being not available for voice over PS when these conditions are no longer met.

NOTE: The status of being not available for voice over PS is used for domain selection for UE originating sessions / calls specified in 3GPP TS 23.221 [6] subclause 7.2a.

### B.3.1.2A Availability for SMS

The UE determines that the UE is able to use SMS using IMS if the UE:

- I) is capable of using the MIME type "application/vnd.3gpp.sms" (see 3GPP TS 24.341 [8L]), such that the MIME type can also be used when accessing the IM CN subsystem using the current IP-CAN;
- II) supports the role of an SM-over-IP sender (see 3GPP TS 24.341 [8L]);
- IIA) determines the PDP context used for SIP signalling exists;
- III) determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media;
- IV) the UE does not determine that SMS over IP is restricted in 3GPP TS 24.341 [8L] subclause 5.2.1.3; and
- V) the 3GPP PS data off status is:
  - "inactive";
  - "active", the UE is in the HPLMN or the EHPLMN, and SMS over IMS is a 3GPP PS data off exempt service; or
  - "active", the UE is in the VPLMN, the UE is configured with an indication that SMS over IMS is a 3GPP PS data off exempt service in a VPLMN, and SMS over IMS is a 3GPP PS data off roaming exempt service.

When above criteria are not matched, the UE determines that SMS using IMS is unavailable.

NOTE: The status that SMS using IMS is unavailable is used for domain selection for UE originating SMS specified in 3GPP TS 23.221 [6] subclause 7.2c.

### B.3.1.3 Authorization header field

Void.

### B.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Upon receiving an INVITE request not including the "precondition" option-tag in the Supported header field and not including the "precondition" option-tag in the Require header field, and the IP-CAN performs network-initiated resource reservation for the UE, the UE:

- 1) if the INVITE request contains an SDP offer and the local resources required at the terminating UE for the received SDP offer are not available:
  - a) shall not alert the user; and
  - b) shall send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. If the INVITE request includes a Supported header field indicating support of reliable provisional responses, the UE shall send the 183 (Session Progress) response reliably. In the 183 (Session Progress) response, the UE shall include an SDP answer; and

- 2) if the INVITE request does not contain an SDP offer and the INVITE request includes a Supported header field indicating support of reliable provisional responses:
  - a) shall generate an SDP offer; and
  - b) if the local resources required at the terminating UE for the generated SDP offer are not available:
    - A) shall not alert the user; and
    - B) shall reliably send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. In the 183 (Session Progress) response, the UE shall include the generated SDP offer.

Upon successful reservation of local resources, if the precondition mechanism is not used by the terminating UE, the UE can send 180 (Ringing) response to the INVITE request and can alert the user.

### B.3.1.5 3GPP PS data off

If the 3GPP PS data off status is "active" the UE shall only send initial requests that:

- 1) are associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are associated with an emergency service; or
- 3) are associated with 3GPP PS data off exempt services configured in the UE using one or more of the following methods:
  - the non\_3GPP\_ICSIIs\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
  - the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the VPLMN;
  - the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
  - the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the 3GPP PS data off status changes from "inactive" to "active" the UE shall release all dialogs that

- 1) are not associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are not associated with an emergency service; and
- 3) are not associated with 3GPP data off exempt services configured in the UE using one or more of the following methods:

- the non\_3GPP\_ICSIIs\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
- the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the VPLMN;- the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
- the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

### B.3.1.6 Transport mechanisms

No additional requirements are defined.

### B.3.1.7 RLOS

Not applicable.

## B.3.2 Procedures at the P-CSCF

### B.3.2.0 Registration and authentication

Void.

### B.3.2.1 Determining network to which the originating user is attached

In order to determine from which network the request was originated the P-CSCF shall check the MCC and MNC fields received in the P-Access-Network-Info header field.

NOTE: The above check can be against more than one MNC code stored in the P-CSCF.

### B.3.2.2 Location information handling

Void.

### B.3.2.3 Prohibited usage of PDN connection for emergency bearer services

If the P-CSCF detects that a UE uses a PDN connection for emergency bearer services for a non-emergency REGISTER request, the P-CSCF shall reject that request by a 403 (Forbidden) response.

NOTE: By assigning specific IP address ranges for a PDN connection for emergency bearer services and configuring those ranges in P-CSCF, the P-CSCF can detect based on the registered Contact address if UE uses an emergency PDN connection for initial registration.

### B.3.2.5 Void

### B.3.2.6 Resource sharing

If P-CSCF supports resource sharing, PCC is supported for this access technology and if according to local policy, the P-CSCF shall apply the procedures in subclause L.3.2.6.

### B.3.2.7 Priority sharing

If P-CSCF supports priority sharing, PCC is supported for this access technology and if according to operator policy, the P-CSCF shall apply the procedures in subclause L.3.2.7.

### B.3.2.8 RLOS

Not applicable.

## B.3.3 Procedures at the S-CSCF

### B.3.3.1 Notification of AS about registration status

Not applicable

### B.3.3.2 RLOS

Not applicable.

---

## B.4 3GPP specific encoding for SIP header field extensions

### B.4.1 Void

---

## B.5 Use of circuit-switched domain

When an emergency call is to be set up over the CS domain, the UE shall attempt it according to the procedures described in 3GPP TS 24.008 [8].

NOTE: 3GPP TS 24.301 [8J] specifies additional requirements for the UE in determining the type of setup message the UE sends to the network when an emergency call is to be set up over the CS domain.

---

## Annex C (normative): UICC and USIM Aspects for access to the IM CN subsystem

### C.1 Scope

This clause describes the UICC and USIM aspects for access to the IM CN subsystem. Additional requirements related to UICC usage for access to the IM CN subsystem are described in 3GPP TS 33.203 [19].

---

### C.2 Derivation of IMS parameters from USIM

In case the UE is loaded with a UICC that contains a USIM but does not contain an ISIM, the UE shall:

- generate a private user identity;
- generate a temporary public user identity; and
- generate a home network domain name to address the SIP REGISTER request to.

All these three parameters are derived from the IMSI parameter in the USIM, according to the procedures described in 3GPP TS 23.003 [3]. Also in this case, the UE shall derive new values every time the UICC is changed, and shall discard existing values if the UICC is removed.

**NOTE:** If there is an ISIM and a USIM on a UICC, the ISIM is used for authentication to the IM CN subsystem, as described in 3GPP TS 33.203 [19]. See also subclause 5.1.1.1A.

---

### C.3 ISIM Location in 3GPP Systems

For 3GPP systems, if ISIM is present, it is contained in UICC.

---

#### C.3A UICC access to IMS

If the UE supports the UICC access to IMS USAT feature defined in 3GPP TS 31.111 [15D] the following procedures in addition to the UE procedures in this specification apply.

If the EF<sub>UICCIARI</sub> contains a list of IARIs associated with active applications installed on the UICC in either the USIM or the ISIM, then when performing the user-initiated registration procedure as described in subclause 5.1.1.2 the UE shall include in the REGISTER request the list of IARIs associated with active applications installed on the UICC in addition to any IARI values for active applications installed on the ME in g.3gpp.iari-ref media feature tag(s) in the Contact header field of the REGISTER request as defined in subclause 7.9.3 and RFC 3840 [62].

If the UE receives from the UICC an initial request for a dialog or a standalone transaction then after decapsulating the request as specified in 3GPP TS 31.111 [15D] the UE shall send the request to the IM CN subsystem as specified in subclause 5.1.2A. When the UE receives from the UICC subsequent requests or responses related to dialogs or transactions already established for UICC applications then after decapsulating the request or response as specified in 3GPP TS 31.111 [15D] the UE shall send the request or response to the IM CN subsystem as specified in subclause 5.1.2A.

**NOTE:** The encapsulated requests and responses transferred between the UICC and UE are complete and valid SIP requests and responses compliant with RFC 3261 [26].

When sending requests or responses received from the UICC to the IM CN subsystem the UE shall modify or include any header fields necessary (such as Route, Via, Contact) in order to conform with the procedures in this specification.

---

## C.4 Update of IMS parameters on the UICC

3GPP TS 31.102 [15C] and 3GPP TS 31.103 [15B] specify the file structure and contents for the preconfigured parameters stored on the USIM and ISIM, respectively, necessary to initiate the registration to the IM CN subsystem. Any of these parameters can be updated via Data Download or a USAT application, as described in 3GPP TS 31.111 [15D]. If one or more EFs are changed and a REFRESH command is issued by the UICC, then the UE reads the updated parameters from the UICC as specified for the REFRESH command in 3GPP TS 31.111 [15D].

If the UE supports the UICC access to IMS USAT feature defined in 3GPP TS 31.111 [15D] and the  $EF_{UICCIARI}$  changes in either the USIM or the ISIM, the UE shall perform the user-initiated reregistration procedure as described in subclause 5.1.1.4 with the new values of the IARI parameter(s) residing on the UICC.

In case of changes to EFs other than the  $EF_{UICCIARI}$ , the UE is not required to perform deregistration but it shall wait for the network-initiated deregistration procedures to occur as described in subclause 5.4.1.5 unless the user initiates deregistration procedures as described in subclause 5.1.1.6. From this point onwards the normal initial registration procedures can occur.

# Annex D (normative): Void

---

# Annex E (normative): IP-Connectivity Access Network specific concepts when using xDSL, Fiber or Ethernet to access IM CN subsystem

## E.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is xDSL, Fiber or Ethernet.

NOTE: Fixed-broadband access in this Annex refers to xDSL, Fiber and Ethernet accesses.

---

## E.2 Fixed broadband aspects when connected to the IM CN subsystem

### E.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the fixed-broadband access network to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the IP Edge node, defined in ETSI ES 282 001 [138] in support of this communication are outside the scope of this document and specified elsewhere.

From the UEs perspective, it is assumed that one or more IP-CAN bearer(s) are provided, in the form of connection(s) managed by the layer 2 (e.g. DSL modem supporting the UE).

In the first instance, it is assumed that the IP-CAN bearer(s) is (are) statically provisioned between the UE and the IP Edge node, defined in ETSI ES 282 001 [138], according to the user's subscription.

It is out of the scope of the current Release to specify whether a single IP-CAN bearer is used to convey both signalling and media flows, or whether several PVC connections are used to isolate various types of IP flows (signalling flows, conversational media, non conversational media...).

The end-to-end characteristics of the fixed-broadband IP-CAN bearer depend on the type of access network, and on network configuration. The description of the network PVC termination (e.g., located in the DSLAM, in the BRAS...) is out of the scope of this annex.

### E.2.2 Procedures at the UE

#### E.2.2.1 Activation and P-CSCF discovery

Fixed-broadband bearer(s) is (are) statically provisioned in the current Release.

Unless a static IP address is allocated to the UE, prior to communication with the IM CN subsystem, the UE shall perform a Network Attachment procedure depending on the used fixed-broadband access type. When using a fixed-broadband access, both IPv4 and IPv6 UEs may access the IM CN subsystem. The UE may request a DNS Server IPv4 address(es) via RFC 2132 [20F] or a DNS Server IPv6 address(es) via RFC 3315 [40].

The methods for P-CSCF discovery are:

- I. When using IPv4, employ the Dynamic Host Configuration Protocol (DHCP) RFC 2132 [20F], the DHCPv4 options for SIP servers RFC 3361 [35A], and RFC 3263 [27A] as described in subclause 9.2.1. When using IPv6, employ Dynamic Host Configuration Protocol for IPv6 (DHCPv6) RFC 3315 [40], the DHCPv6 options for SIP servers RFC 3319 [41] and DHCPv6 options for Domain Name Servers (DNS) RFC 3646 [56C] as

described in subclause 9.2.1. In case the DHCP server provides several P-CSCF addresses or FQDNs to the UE, the UE shall select the P-CSCF address or FQDN as indicated in RFC 3319 [41]. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the UE is implementation specific.

II. The UE selects a P-CSCF from the list in the IMS management object as specified in 3GPP TS 24.167 [8G].

The UE shall use method II to select a P-CSCF if the IMS management object contains the P-CSCF list. Otherwise, the UE shall use method I to select a P-CSCF.

### E.2.2.1A Modification of a fixed-broadband connection used for SIP signalling

Not applicable.

### E.2.2.1B Re-establishment of a fixed-broadband connection used for SIP signalling

Not applicable.

### E.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure uses the keep-alive procedures described in RFC 6223 [143].

If the P-CSCF fails to respond to keep-alive requests the UE shall acquire a different P-CSCF address using any of the methods described in the subclause E.2.2.1 and perform an initial registration as specified in subclause 5.1.

### E.2.2.2 Void

### E.2.2.3 Void

### E.2.2.4 Void

### E.2.2.5 Fixed-broadband bearer(s) for media

#### E.2.2.5.1 General requirements

The UE can establish media streams that belong to different SIP sessions on the same fixed-broadband bearer.

#### E.2.2.5.1A Activation or modification of fixed-broadband bearers for media by the UE

If the UE receives indication within the SDP according to RFC 3524 [54] that media stream(s) belong to group(s), and if several fixed-broadband bearers are available to the UE for the session, the media stream(s) may be sent on separate fixed-broadband bearers according to the indication of grouping. The UE may freely group media streams to fixed-broadband bearers in case no indication of grouping is received from the P-CSCF.

If the UE receives media grouping attributes in accordance with RFC 3524 [54] that it cannot provide within the available fixed-broadband bearer(s), then the UE shall handle such SDP offers in accordance with RFC 3388 [53].

The UE can receive a media authorization token in the P-Media-Authorization header field from the P-CSCF according to RFC 3313 [31]. If a media authorization token is received in the P-Media-Authorization header field when a SIP session is initiated, the UE shall reuse the existing fixed-broadband bearer(s) and ignore the media authorization token.

#### E.2.2.5.1B Activation or modification of fixed-broadband bearers for media by the network

Not applicable.

### E.2.2.5.1C Deactivation of fixed-broadband bearers for media

Not applicable.

### E.2.2.5.2 Special requirements applying to forked responses

Since the UE is unable to perform bearer modification, forked responses place no special requirements on the UE.

### E.2.2.5.3 Unsuccessful situations

Not applicable.

## E.2.2.6 Emergency service

### E.2.2.6.1 General

If attached to network via fixed-broadband access technology, the UE shall always consider being attached to its home operator's network for the purpose of emergency calls.

NOTE: In fixed-broadband the UE is unable to receive any indication from the network, that would allow the UE to determine, whether it is currently attached to its home operator's network or to a different network, so the UE assumes itself always attached to the home operator's network when connected via fixed-broadband access technology.

#### E.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### E.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

### E.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### E.2.2.6.3 Current location discovery during an emergency call

Void.

---

## E.2A Usage of SDP

### E.2A.0 General

Not applicable.

### E.2A.1 Impact on SDP offer / answer of activation or modification of xDSL bearer for media by the network

Not applicable.

## E.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

## E.2A.3 Emergency service

No additional procedures defined.

---

# E.3 Application usage of SIP

## E.3.1 Procedures at the UE

### E.3.1.0 Registration and authentication

In order to reach IMS in some access networks, the UE may support:

- address and/or port number conversions provided by a NA(P)T or NA(P)T-PT as described in annex F and annex K; and
- UE requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y].

If a UE supports one or both of these capabilities then a UE may progressively try them to overcome failure to reach the IMS. Use of these capabilities shall have the following priority order:

- 1) UE uses neither capability because reaching the IMS without an intervening NA(P)T, NA(P)T-PT, or tunnel is preferred.
- 2) UE may use address and/or port number conversions provided by a NA(P)T or NA(P)T-PT as described in either annex F or annex K.
- 3) UE may use the UE requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y]. If the UE uses the UE-requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y], the UE considers itself to:
  - be configured to send keep-alives;
  - be directly connected to an IP-CAN for which usage of NAT is defined; and
  - be behind a NAT.

Optional procedures apply when the UE is supporting traversal of restrictive non-3GPP access network using STUN/TURN/ICE, as follows:

- a) the protection of SIP messages is provided by utilizing TLS as defined in 3GPP TS 33.203 [19];
- b) the mechanisms specified in this annex shall only be applicable when the IP traffic to the IMS core does not traverse through the Evolved Packet Core (EPC);
- c) the UE shall establish the TLS connection to the P-CSCF on port 443 as defined in 3GPP TS 33.203 [19]. The UE shall use SIP digest with TLS for registration as specified in subclause 5.1. If the TLS connection is established successfully, the UE sends SIP signalling over the TLS connection to the P-CSCF;
- d) the UE shall support the keep-alive procedures described in RFC 6223 [143];

NOTE 1: If the UE is configured to use an HTTP proxy, the UE use the HTTP CONNECT method specified in RFC 2817 [220] to request the HTTP proxy to establish the TCP connection with the P-CSCF. Once the UE has received a positive reply from the proxy that the TCP connection has been established, the UE initiates the TLS handshake with the P-CSCF and establishes the TLS connection.

- e) the procedures described in subclause K.5.2 apply with the additional procedures described in the present subclause;
- f) when using the ICE procedures for traversal of restrictive non-3GPP access network, the UE shall support the ICE TCP as specified in RFC 6544 [131] and TURN TCP as specified in RFC 6062 [221].
- g) if the UE is configured to use TURN over TCP on port 80, the UE shall establish the TCP connection to TURN server on port 80. If the UE is configured to use TURN over TLS on port 443, the UE shall establish the TLS connection to the TURN server on port 443 as defined in 3GPP TS 33.203 [19]. If the UE is configured to use both, the UE should prefer to use TURN over TCP on port 80 to avoid TLS overhead;
- h) if the connection is established successfully, the UE sends TURN control messages and media packets over the connection as defined in RFC 5766 [101].

NOTE 2: If the UE is configured to use an HTTP proxy, the UE use the HTTP CONNECT method specified in RFC 2817 [220] to request the HTTP proxy to establish the TCP connection with the TURN server. Then, if the UE is configured to use TURN over TLS on port 443 and the UE has received a positive reply from the proxy that the TCP connection has been established, the UE initiates the TLS handshake with the TURN server and establishes the TLS connection.

### E.3.1.0a IMS\_Registration\_handling policy

Not applicable.

#### E.3.1.1 P-Access-Network-Info header field

The UE may, but need not, include the P-Access-Network-Info header field where indicated in subclause 5.1.

##### E.3.1.1A Cellular-Network-Info header field

Not applicable.

#### E.3.1.2 Availability for calls

Not applicable.

##### E.3.1.2A Availability for SMS

Void.

#### E.3.1.3 Authorization header field

When using SIP digest or SIP digest without TLS, the UE need not include an Authorization header field on sending a REGISTER request, as defined in subclause 5.1.1.2.1.

NOTE: In case the Authorization header field is absent, the mechanism only supports that one public user identity is associated with only one private user identity. The public user identity is set so that it is possible to derive the private user identity from the public user identity by removing SIP URI scheme and the following parts of the SIP URI if present: port number, URI parameters, and To header field parameters. Therefore, the public user identity used for registration in this case cannot be shared across multiple UEs. Deployment scenarios that require public user identities to be shared across multiple UEs that don't include an private user identity in the initial REGISTER request can be supported as follows:

- Assign each sharing UE a unique public user identity to be used for registration,

- Assign the shared public user identities to the implicit registration set of the unique registering public user identities assigned to each sharing UE.

#### E.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

#### E.3.1.5 3GPP PS data off

Not applicable.

#### E.3.1.6 Transport mechanisms

No additional requirements are defined.

#### E.3.1.7 RLOS

Not applicable.

### E.3.2 Procedures at the P-CSCF

#### E.3.2.0 Registration and authentication

The P-CSCF may support UEs connected via restrictive non-3GPP access network.

If the P-CSCF supports UEs connected via restrictive non-3GPP access network, when the P-CSCF receives a 200 (OK) response to a REGISTER request, if the contact address of REGISTER request contains an IP address assigned by the EFTF, and the UE's Via header field contains a "keep" header field parameter, then the P-CSCF shall add a value to the "keep" header field parameter of the UE's Via header field of the 200 (OK) response as defined in RFC 6223 [143].

Optional procedures apply when the P-CSCF is supporting traversal of restrictive non-3GPP access network using STUN/TURN/ICE, as follows:

NOTE: In this scenario, the restrictive non-3GPP access network coexists with NA(P)T device located in the customer premises domain:

- a) the protection of SIP messages is provided by utilizing TLS as defined in 3GPP TS 33.203 [19];
- b) the P-CSCF supporting these additional procedures should use SIP digest with TLS as defined in subclause 5 and the P-CSCF should insert an IMS-ALG on the media plane;
- c) the mechanisms specified in this annex shall only be applicable when the IP traffic to the IMS core does not traverse through the Evolved Packet Core (EPC);
- d) the P-CSCF shall support the procedures defined in subclause 5.2, with the exception that the P-CSCF shall use SIP over TLS on port 443 as defined in 3GPP TS 33.203 [19];
- e) when the UE has indicated support of the keep-alive mechanism defined in RFC 6223 [143], the P-CSCF shall indicate to the UE that it supports the keep-alive mechanism; and
- f) the IMS-ALG in the P-CSCF shall support ICE procedures, as defined in subclause 6.7.2.7.

### E.3.2.1 Determining network to which the originating user is attached

In order to determine from which network the request was originated the P-CSCF shall check if the location information received in the network provided and/or UE provided "dsl-location", "eth-location" or "fiber-location" parameter in the P-Access-Network-Info header field(s) belongs to a location in the same country.

NOTE 1: If local policy does not require the insertion of P-Access-Network-Info header field in the P-CSCF even if it is missing in the received initial request, the P-CSCF can assume that the request is initiated by fixed broadband UE in the same country.

NOTE 2: If the location information in the network provided and UE provided "dsl-location", "eth-location" or "fiber-location" parameters (in a request that includes two P-Access-Network-Info header fields) is contradictory, or the two P-Access-Network-Info header fields indicate different access types the P-CSCF ignores either the network provided or the UE provided information according to operator policy.

### E.3.2.2 Location information handling

Upon receipt of an initial request for a dialog or standalone transaction or an unknown method, the P-CSCF based on local policy may include a P-Access-Network-Info header field. The value of the "dsl-location", "eth-location" or "fiber-location" parameter shall be the value as received in the Location-Information header in the User-Data Answer command as specified in ETSI ES 283 035 [98].

NOTE: The way the P-CSCF deduce that the request comes from a UE connected through xDSL access is implementation dependent.

### E.3.2.3 Void

### E.3.2.4 Void

### E.3.2.5 Void

### E.3.2.6 Resource sharing

Not applicable.

### E.3.2.7 Priority sharing

Not applicable.

### E.3.2.8 RLOS

Not applicable.

## E.3.3 Procedures at the S-CSCF

### E.3.3.1 Notification of AS about registration status

Not applicable

### E.3.3.2 RLOS

Not applicable.

---

## E.4 3GPP specific encoding for SIP header field extensions

### E.4.1 Void

---

## E.5 Use of circuit-switched domain

There is no CS domain in this access technology.

---

# Annex F (normative): Additional procedures in support for hosted NAT

NOTE: This subclause describes the mechanism for support of the hosted NAT scenario. This does not preclude other mechanisms but they are out of the scope of this annex.

---

## F.1 Scope

This annex describes the UE and P-CSCF procedures in support of hosted NAT. In this scenario, both the media flows and the SIP signalling both traverse a NA(P)T device located in the customer premises domain. The term "hosted NAT" is used to address this function.

When receiving an initial SIP REGISTER request without integrity protection, the P-CSCF can, determine whether to perform the hosted NAT procedures for the user identified by the REGISTER request by comparing the address information in the top-most SIP Via header field with the IP level address information from where the request was received. The P-CSCF will use the hosted NAT procedure only when the address information do not match.

NOTE: There is no need for the P-CSCF to resolve a domain name in the Via header field when UDP encapsulated tunnel mode for IPsec is used. The resolution of a domain name in the Via header field is not required by RFC 3261 [26].

In order to provide hosted NAT traversal for SIP REGISTER requests without integrity protection and the associated responses, the P-CSCF makes use of the "received" header field parameter as described in RFC 3261 [26] and, in addition, if UDP is used, makes use of the "rport" header field parameter as described in RFC 3581 [56A]. The hosted NAT traversal for protected SIP messages is provided by applying UDP encapsulation to IPsec packets in accordance with RFC 3948 [63A].

Alternatively to the procedures defined in subclause F.2 which are employed to support the hosted NAT scenario where the security solution is based on UDP encapsulated IPsec as defined in 3GPP TS 33.203 [19], subclause F.4 provides procedures for NAT traversal for security solutions that are not defined in 3GPP TS 33.203 [19]. Use of such security solutions is outside the scope of this document.

---

## F.2 Application usage of SIP

### F.2.1 UE usage of SIP

#### F.2.1.1 General

This subclause describes the UE SIP procedures for supporting hosted NAT scenarios. The description enhances the procedures specified in subclause 5.1.

The UE shall support the symmetric response routing mechanism according to RFC 3581 [56A].

#### F.2.1.2 Registration and authentication

##### F.2.1.2.1 General

The text in subclause 5.1.1.1 applies without changes

##### F.2.1.2.1A Parameters contained in the ISIM

The text in subclause 5.1.1.1A applies without changes

### F.2.1.2.1B Parameters provisioned to a UE without ISIM or USIM

The text in subclause 5.1.1.1B applies without changes.

### F.2.1.2.2 Initial registration

The procedures described in subclause 5.1.1.2.1 apply with the additional procedures described in the present subclause.

NOTE 1: In accordance with the definitions given in subclause 3.1 the IP address acquired initially by the UE in a hosted NAT scenario is the UE private IP address.

On sending a REGISTER request, the UE shall populate the header fields as indicated in subclause 5.1.1.2.1 with the exceptions of subitems c) and d) which are modified as follows

The UE shall populate:

- c) a Contact header field according to the following rules: if the REGISTER request is sent without integrity protection, the Contact header field shall be set to include SIP URI(s) containing the private IP address of the UE in the hostport parameter or FQDN. If the UE supports GRUU, the UE shall include a "+sip.instance" header field parameter containing the instance ID. If the REGISTER request is integrity protected, the UE shall include the public IP address or FQDN in the hostport parameter. The UE shall only use a FQDN in a protected REGISTER request, if it is ensured that the FQDN resolves to the public IP address of the NAT. If the UE supports GRUU, the UE shall include a "+sip.instance" header field parameter containing the instance ID. The UE shall include all supported ICSI values (coded as specified in subclause 7.2A.8.2) in a g.3gpp.icsi-ref media feature tag as defined in subclause 7.9.2 and RFC 3840 [62] for the IMS communication services it intends to use, and IARI values (coded as specified in subclause 7.2A.9.2), for the IMS applications it intends to use in a g.3gpp.iari-ref media feature tag as defined in subclause 7.9.3 and RFC 3840 [62];

NOTE 2: The UE will learn its public IP address from the "received" header field parameter in the topmost Via header field in the 401 (Unauthorized) response to the unprotected REGISTER request.

- d) a Via header field according to the following rules: if the REGISTER request is sent without integrity protection, the Via header field shall be set to include the private IP address or FQDN of the UE in the sent-by field. If the REGISTER request is integrity protected, the UE shall include the public IP address or FQDN in the sent-by field. The UE shall only use a FQDN in a protected REGISTER request, if it is ensured that the FQDN resolves to the public IP address of the NAT. Unless the UE has been configured to not send keep-alives, it shall include a "keep" header field parameter with no value in the Via header field, in order to indicate support of sending keep-alives associated with, the registration, as described in RFC 6223 [143];

NOTE 3: If the UE specifies a FQDN in the host parameter in the Contact header field and in the sent-by field in the Via header field of an unprotected REGISTER request, this FQDN will not be subject to any processing by the P-CSCF or other entities within the IM CN subsystem. The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

If IMS AKA is used as a security mechanism, on sending a REGISTER request, as defined in subclause 5.1.1.2.1, the UE shall additionally populate the header fields as defined in subclause 5.1.1.2.2, with the exceptions of subitems c), and d) which are modified as follows:

- d) the Security-Client header field set to specify the security mechanisms the UE supports, the IPsec layer algorithms the UE supports and the parameters needed for the security association setup. The UE shall support the setup of two pairs of security associations as defined in 3GPP TS 33.203 [19]. The syntax of the parameters needed for the security association setup is specified in Annex H of 3GPP TS 33.203 [19]. The UE shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The UE shall support the IPsec layer algorithms for integrity protection and for encryption as defined in 3GPP TS 33.203 [19], and shall announce support for them according to the procedures defined in RFC 3329 [48]. In addition to transport mode the UE shall support UDP encapsulated tunnel mode as per RFC 3948 [63A] and shall announce support for both modes as described in TS 33.203 [19];

When a 401 (Unauthorized) response to a REGISTER is received and this response is received without integrity protection, the procedures described in subclause 5.1.1.2.1 apply with the following additions:

The UE shall compare the IP address in the "received" header field parameter with the corresponding value in the sent-by parameter in the topmost Via header field to detect if the UE is behind a NAT. If the comparison indicates that the respective values are the same, the UE concludes that it is not behind a NAT.

- If the UE is not behind a NAT, the UE shall proceed with the procedures described in subclause 5.1 of the main body of this specification;
- If the UE is behind a NAT, the UE shall verify using the Security-Server header field that mode "UDP-enc-tun" is selected. If the verification succeeds the UE shall store the IP address contained in the "received" header field parameter as the UE public IP address. If the verification does not succeed the UE shall abort the registration. When the UE detects that it is behind a NAT, the UE may include a transport=tcp URI parameter in the Contact header when it sends a protected REGISTER.

NOTE 4: The UE includes a transport=tcp parameter to ensure that P-CSCF uses TCP connection when it receives an initial request for a dialog or a request for a standalone transaction destined for the UE.

In addition, when a 401 (Unauthorized) response to a REGISTER is received (with or without integrity protection) the UE shall behave as described in subclause F.2.1.2.5.

When the UE, that is behind a NAT, receives a 400 (Bad Request) response with 301 Warning header field indicating "incompatible network address format" to the unprotected REGISTER request, the UE shall randomly select new values for the protected server port and the protected client port, and perform new initiate registration procedure by sending an unprotected REGISTER request containing the new values in the Security-Client header field.

**Editor's Note: [GINI CR#3968] The impact of bulk number registration procedures according to RFC 6140 [191] on the additional procedures in support for hosted NAT is FFS.**

#### F.2.1.2.3 Initial subscription to the registration-state event package

The procedures described in subclause 5.1.1.3 apply with the additional procedures described in subclause F.2.1.4.1.

#### F.2.1.2.4 User-initiated re-registration

The procedures described in subclause 5.1.1.4.1 apply with the additional procedures described in the present subclause.

On sending a REGISTER request that does not contain a challenge response, the UE shall populate the header fields as indicated in subclause 5.1.1.4.1 with the exception of subitems c) and d) which are modified as follows.

The UE shall populate:

- c) a Contact header field set to include SIP URI(s) that contain(s) in the hostport parameter the public IP address of the UE or FQDN, and containing the instance ID of the UE in the "+sip.instance" header field parameter, if the UE supports GRUU. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT. The UE shall include all supported ICSI values (coded as specified in subclause 7.2A.8.2) in a g.3gpp.icsi-ref media feature tag as defined in subclause 7.9.2 and RFC 3840 [62] for the IMS communication services it intends to use, and IARI values (coded as specified in subclause 7.2A.9.2), for the IMS applications it intends to use in a g.3gpp.iari-ref media feature tag as defined in subclause 7.9.3 and RFC 3840 [62]. If the UE has detected it is behind a NAT, the UE may include a transport=tcp URI parameter in the Contact header;
- d) a Via header field set to include the public IP address or FQDN of the UE in the sent-by field. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT. For the TCP, the response is received on the TCP connection on which the request was sent. If the UE previously has previously negotiated sending of keep-alives associated with the registration, it shall include a "keep" header field parameter with no value in the Via header field, in order to indicate continuous support to send keep-alives, as described in RFC 6223 [143];

NOTE 1: The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

When the UE, that is behind a NAT, receives a 400 (Bad Request) response with 301 Warning header field indicating "incompatible network address format" to the REGISTER request that does not contain a challenge response, the UE shall randomly select a new value for the protected client port, and send the REGISTER request containing the new values in the Security-Client header field.

NOTE 2: The protected server port stays fixed for a UE until all public user identities of the UE have been de-registered.

Editor's Note: [GINI CR#3968] The impact of bulk number registration procedures according to RFC 6140 [191] on the additional procedures in support for hosted NAT is FFS.

## F.2.1.2.5 Authentication

### F.2.1.2.5.1 IMS AKA - general

The procedures of subclause 5.1.1.5.1 apply with with the additional procedures described in the present subclause.

On receiving a 401 (Unauthorized) response to the REGISTER request and the response is deemed to be valid, the UE shall behave as of subclause 5.1.1.5.1 with the exception of subitem 3) which is modified as follows.

The UE shall:

- 3) send another REGISTER request using the temporary set of security associations to protect the message. The header fields are populated as defined for the initial request (see subclause F.2.1.2.2), with the addition that the UE shall include an Authorization header field containing the private user identity and the authentication challenge response calculated by the UE using RES and other parameters, as described in RFC 3310 [49]. The UE shall also insert the Security-Client header field that is identical to the Security-Client header field that was included in the previous REGISTER request (i.e. the REGISTER request that was challenged with the received 401 (Unauthorized) response). The UE shall also insert the Security-Verify header field into the request, by mirroring in it the content of the Security-Server header field received in the 401 (Unauthorized) response. The UE shall set the Call-ID of the integrity protected REGISTER request which carries the authentication challenge response to the same value as the Call-ID of the 401 (Unauthorized) response which carried the challenge.

Whenever the 200 (OK) response is not received before the temporary SIP level lifetime of the temporary set of security associations expires or a 403 (Forbidden) response is received, the UE shall consider the registration to have failed. The UE shall delete the temporary set of security associations it was trying to establish, and use the old set of security associations. The UE should send an unprotected REGISTER request according to the procedure specified in subclause F.2.1.2.2 if the UE considers the old set of security associations to be no longer active at the P-CSCF.

### F.2.1.2.5.2 Void

### F.2.1.2.5.3 IMS AKA abnormal cases

The text in subclause 5.1.1.5.3 applies without changes.

### F.2.1.2.5.4 SIP digest – general

Not applicable.

### F.2.1.2.5.5 SIP digest – abnormal procedures

Not applicable.

### F.2.1.2.5.6 SIP digest with TLS – general

Not applicable.

### F.2.1.2.5.7 SIP digest with TLS – abnormal procedures

Not applicable.

### F.2.1.2.5.8 Abnormal procedures for all security mechanisms

The text in subclause 5.1.1.5.8 applies without changes.

#### F.2.1.2.5A Network-initiated re-authentication

The text in subclause 5.1.1.5A applies without changes.

#### F.2.1.2.5B Change of IPv6 address due to privacy

The text in subclause 5.1.1.5B applies without changes.

#### F.2.1.2.6 User-initiated deregistration

The procedures of subclause 5.1.1.6.1 apply with with the additional procedures described in the present subclause.

On sending a REGISTER request, the UE shall populate the header fields as indicated in subclause 5.1.1.6 with the exception of subitems d) and e) which are modified as follows.

The UE shall populate:

- c) a Contact header field set to either the value of "\*" or SIP URI(s) that contain(s) in the hostport parameter the IP address of the UE or FQDN; and containing the instance ID of the UE in the "+sip.instance" header field parameter, if the UE supports GRUU. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT;
- d) a Via header field set to include the IP address or FQDN of the UE in the sent-by field. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT;

NOTE 1: In case of hosted NAT traversal only the UE public IP addresses are bound to security associations.

NOTE 2: The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

**Editor's Note: [GINI CR#3968] The impact of bulk number registration procedures according to RFC 6140 [191] on the additional procedures in support for hosted NAT is FFS.**

#### F.2.1.2.7 Network-initiated deregistration

The procedures of subclause 5.1.1.7 apply with with the additional procedures described in the present subclause.

Upon receipt of a NOTIFY request on the dialog which was generated during subscription to the reg event package as described in subclause 5.1.1.3, including one or more <registration> element(s) which were registered by this UE with:

- the state attribute set to "terminated" and the event attribute set to "rejected" or "deactivated"; or
- the state attribute set to "active" and the state attribute within the <contact> element belonging to this UE set to "terminated", and associated event attribute element to "rejected" or "deactivated";

the UE shall remove all registration details relating to these public user identities. In case of a "deactivated" event attribute, the UE shall start the initial registration procedure as described in subclause F.2.1.2.2. In case of a "rejected" event attribute, the UE shall release all dialogs related to those public user identities.

### F.2.1.3 Subscription and notification

The text in subclause 5.1.2 applies without changes.

### F.2.1.4 Generic procedures applicable to all methods excluding the REGISTER method

#### F.2.1.4.1 UE originating case

The procedures described in subclause 5.1.2A.1 apply with the additional procedures described in the present subclause.

When the UE sends any request, the requirements in subclause 5.1.2A.1 are replaced by the following requirements. The UE shall include:

- a Via header field set to include the public IP address of the UE or FQDN and the protected server port in the sent-by field. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT; and if this is a request for a new dialog, and the request includes a Contact header field, then the UE should populate the Contact header field as follows:
  - 1) if a public GRUU value ("pub-gruu" header field parameter) has been saved associated with the public user identity to be used for this request, and the UE does not indicate privacy of the P-Asserted-Identity, then insert the public GRUU ("pub-gruu" header field parameter) value in the Contact header field as specified in RFC 5627 [93]; or
  - 2) if a temporary GRUU value ("temp-gruu" header field parameter) has been saved associated with the public user identity to be used for this request, and the UE does indicate privacy of the P-Asserted-Identity, then insert the temporary GRUU ("temp-gruu" header field parameter) value in the Contact header field as specified in RFC 5627 [93].

If this is a request within an existing dialog, and the request includes a Contact header field, and the contact address previously used in the dialog was a GRUU, then the UE should insert the previously used GRUU value in the Contact header field as specified in RFC 5627 [93].

If the UE did not insert a GRUU in the Contact header field, then the UE shall include the public IP address of the UE or FQDN and the protected server port in the hostport parameter in any Contact header field that is otherwise included. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT.

**NOTE:** The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

The UE shall discard any SIP response that is not integrity protected and is received from the P-CSCF outside of the registration and authentication procedures. The requirements on the UE within the registration and authentication procedures are defined in subclause F.2.1.2.4.

When a SIP transaction times out, i.e. timer B, timer F or timer H expires at the UE, the UE may behave as if timer F expired, as described in subclause F.2.1.2.3.

#### F.2.1.4.2 UE terminating case

The procedures described in subclause 5.1.2A.2 apply with the additional procedures described in the present subclause.

When the UE sends any response, the requirements in subclause 5.1.2A.1 are replaced by the following requirement.

If the response includes a Contact header field, and the response is not sent within an existing dialog, then the UE should populate the Contact header field as follows:

- 1) if a public GRUU value ("pub-gruu" header field parameter) has been saved associated with the public user identity from the P-Called-Party-ID header field, and the UE does not indicate privacy of the P-Asserted-Identity, then insert the public GRUU ("pub-gruu" header field parameter) value in the Contact header field as specified in RFC 5627 [93]; and
- 2) if a temporary GRUU value ("temp-gruu" header field parameter) has been saved associated with the public user identity from the P-Called-Party-ID header field, and the UE does indicate privacy of the P-Asserted-Identity, then the UE should insert the temporary GRUU ("temp-gruu" header field parameter) value in the Contact header field as specified in RFC 5627 [93].

If the UE did not insert a GRUU in the Contact header field, then the UE shall:

- include the public IP address of the UE or FQDN and the protected server port in the hostport parameter in any Contact header field that is otherwise included. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT.

**NOTE:** The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

The UE shall discard any SIP request that is not integrity protected and is received from the P-CSCF outside of the registration and authentication procedures. The requirements on the UE within the registration and authentication procedures are defined in subclause F.2.1.2.

## F.2.2 P-CSCF usage of SIP

### F.2.2.1 Introduction

This subclause describes the SIP procedures for supporting hosted NAT scenarios.

The description enhances the procedures specified in subclause 5.2.

The P-CSCF shall support the symmetric response routing mechanism according to RFC 3581 [56A].

**NOTE:** Symmetric response routing is used to support hosted NAT and applicable only to initial, unprotected REGISTER requests and corresponding responses.

### F.2.2.2 Registration

The procedures described in subclause 5.2.2 apply with the additional procedures described in the present subclause.

When the P-CSCF receives a REGISTER request from the UE, the P-CSCF shall behave as of subclause 5.2.2.1.

If IMS AKA is the security mechanism, when the P-CSCF receives a REGISTER request from the UE, the P-CSCF shall perform the procedures of subclause 5.2.2.2 with the following exception to items 2) and 3):

2) in case the REGISTER request was received without integrity protection, then:

- a) check the existence of the Security-Client header field. If the Security-Client header field is not present, then the P-CSCF shall return a suitable 4xx response. If the Security-Client header field is present the P-CSCF shall:
  - in case the UE indicated support for "UDP-enc-tun" then remove and store it.
  - in case the UE does not indicate support for "UDP-enc-tun" then:
    - if the host portion of the sent-by field in the topmost Via header field contains an IP address that differs from the source address of the IP packet, silently drop the REGISTER;
    - otherwise continue with procedures as of subclause 5.2.2.

**NOTE 1:** If the UE does not indicate support for "UDP-enc-tun" and the P-CSCF detects that the UE is located behind a NAT device, then the P-CSCF can just drop the REGISTER to avoid unnecessary signalling traffic.

- b) if the host portion of the sent-by field in the topmost Via header field contains a FQDN, or if it contains an IP address that differs from the source address of the IP packet, the P-CSCF shall:
  - add a "received" header field parameter in accordance with the procedure defined in RFC 3581 [56A]. If the "rport" header field parameter is included in the Via header field, the P-CSCF shall also set the value of the "rport" header field parameter to the source port of the request in accordance with the procedure defined in RFC 3581 [56A]; and
  - check that no any previously registered UE has either the same public IP address (allocated by the NAT and indicated in the Via header field) and the protected server port (specified in the Security-Client header field) or the same public IP address and the protected client port (specified in the Security-Client header field). If there is such UE, the P-CSCF shall return a 400 (Bad Request) response with 301 Warning header field indicating "incompatible network address format" to the unprotected REGISTER request. Otherwise, the P-CSCF shall forward the REGISTER request.

**NOTE 2:** If two UEs are behind the same NAT, the NAT can assign to them the same public IP address (but different NAT's port). Hence, the two respective UE will have different protected server port numbers, and different protected client port numbers.

3) in case the REGISTER request was received integrity protected, then the P-CSCF shall:

- a) check the security association which protected the request. If the security association is a temporary one, the P-CSCF shall:

- in case the host parameter in the Contact address is in the form of a FQDN, ensure that the given FQDN will resolve (e.g., by reverse DNS lookup) to the IP address bound to the security association;
  - in case the P-CSCF has detected earlier that the UE is located behind a NAT, retrieve port\_Uenc from the encapsulating UDP header of the packet received and complete configuration of the temporary set of security associations by configuring port\_Uenc in each of the temporary security associations;
  - check whether the request contains a Security-Verify header field in addition to a Security-Client header field. If there are no such header fields, then the P-CSCF shall return a suitable 4xx response. If there are such header fields, then the P-CSCF shall compare the content of the Security-Verify header field with the content of the Security-Server header field sent earlier and the content of the Security-Client header field with the content of the Security-Client header field received in the challenged REGISTER. If those do not match, then there is a potential man-in-the-middle attack. The request should be rejected by sending a suitable 4xx response. If the contents match, the P-CSCF shall remove the Security-Verify and the Security-Client header field;
- b) if the security association the REGISTER request was received on, is an already established one, then the P-CSCF shall:
- remove the Security-Verify header field if it is present;
  - check if the Security-Client header field containing new parameter values is present, and:
    - if this header field or any required parameter is missing, then the P-CSCF shall return a suitable 4xx response.
    - if this header field and the required parameters are present, then the P-CSCF shall check that no any previously registered UE has the same public IP address and the protected client port (specified in the Security-Client header field). If there is such UE, the P-CSCF shall return a 400 (Bad Request) response with 301 Warning header field indicating "incompatible network address format" to the REGISTER request. Otherwise, the P-CSCF shall remove and store the Security-Client header field before forwarding the request to the S-CSCF;

NOTE 3: When sending the protected REGISTER request to the P-CSCF, the UE will not modify the protected server port value, since the protected server port value stays fixed for a UE until all public user identities of the UE have been de-registered.

When the P-CSCF receives a 401 (Unauthorized) response to an unprotected REGISTER request:

- 1) if this response contains a "received" header field parameter in the Via header field associated with the UE;
- 2) if the request associated with the response was received:
  - A) using UDP and this response contains a "rport" header field parameter in the Via header field associated with the UE; or
  - B) using TCP; and
- 3) the UE indicated support for "UDP-enc-tun" IPsec mode;

the P-CSCF shall:

- 1) delete any temporary set of security associations established towards the UE;
- 2) remove the "ck" and "ik" WWW-Authenticate header field parameters contained in the 401 (Unauthorized) response and bind the values to the proper private user identity and to the temporary set of security associations which will be setup as a result of this challenge. The P-CSCF shall forward the 401 (Unauthorized) response to the UE if and only if the "ck" and "ik" header field parameters have been removed;
- 3) insert a Security-Server header field in the response, containing the P-CSCF security list and the parameters needed for the security association setup, as specified in Annex H of 3GPP TS 33.203 [19]. The P-CSCF shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The P-CSCF shall support the IPsec layer algorithms for integrity protection and for encryption as defined in 3GPP TS 33.203 [19]. The P-CSCF shall indicate "UDP-enc-tun" as the only IPsec mode;

- 4) set up the temporary set of security associations with a temporary SIP level lifetime between the UE and the P-CSCF for the user identified with the private user identity. The P-CSCF shall select UDP encapsulated tunnel mode and shall leave the value for port-Uenc unspecified in each of the temporary security associations. For further details see 3GPP TS 33.203 [19] and RFC 3329 [48]. The P-CSCF shall set the temporary SIP level lifetime for the temporary set of security associations to the value of reg-await-auth timer; and
- 5) send the 401 (Unauthorized) response unprotected to the UE using the mechanisms described in RFC 3261 [26] and RFC 3581 [56A], i.e. in case UDP is used as transport protocol the P-CSCF shall send the response to the IP address indicated in the "received" header field parameter and to the port indicated in the "rport" header field parameter of the Via header field associated with the UE. In case UDP is used as transport protocol, the P-CSCF shall use the IP address and the port on which the REGISTER request was received as source IP address and the source port when sending the response back to the UE.

When the P-CSCF receives a 401 (Unauthorized) response to a protected REGISTER request and that REGISTER request was protected by an old set of security associations that use UDP encapsulated tunnel mode, the P-CSCF shall:

- 1) delete any temporary set of security associations established towards the UE;
- 2) remove the "ck" and "ik" WWW-Authenticate header field parameters contained in the 401 (Unauthorized) response and bind the values to the proper private user identity and to the temporary set of security associations which will be setup as a result of this challenge. The P-CSCF shall forward the 401 (Unauthorized) response to the UE if and only if the "ck" and "ik" header field parameters have been removed;
- 3) insert a Security-Server header field in the response, containing the P-CSCF security list and the parameters needed for the security association setup, as specified in Annex H of 3GPP TS 33.203 [19]. The P-CSCF shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The P-CSCF shall support the IPsec layer algorithms for integrity protection and encryption as defined in 3GPP TS 33.203 [19]. The P-CSCF shall indicate "UDP-enc-tun" as the IPsec mode;
- 4) set up the temporary set of security associations with a temporary SIP level lifetime between the UE and the P-CSCF for the user identified with the private user identity. The P-CSCF shall select UDP encapsulated tunnel mode and shall specify the same port\_Uenc that was used in the old set of security associations. The P-CSCF shall set the temporary SIP level lifetime for the temporary set of security associations to the value of reg-await-auth timer; and
- 5) send the 401 (Unauthorized) response to the UE using the old set of security associations.

Otherwise, when the P-CSCF receives a 401 (Unauthorized) response to an unprotected REGISTER request and:

- this response does not contain a "received" header field parameter in the Via header field associated with the UE;
- this response does not contain "rport" header field parameter in the Via header field associated with the UE and the request associated with the response was received using UDP; or
- when the P-CSCF receives a 401 (Unauthorized) response to a protected REGISTER request and that REGISTER request was protected by an old set of security associations that do not use UDP encapsulated tunnel mode;

the P-CSCF shall proceed as described in subclause 5.2.2.2.

## F.2.3 S-CSCF usage of SIP

### F.2.3.1 S-CSCF usage of SIP

#### F.2.3.1.1 Protected REGISTER with IMS AKA as a security mechanism

The procedures at the S-CSCF described in subclause 5.4.1.2.2 apply.

NOTE: When two UEs that are behind the same NAT register their contact addresses, the NAT can assign to them the same public IP address (but different NAT's ports). If these two UEs select the same protected server port number, and register via different P-CSCFs, then they will have the same contact addresses (i.e. same IP address and protected server port). However, any request targeted to either UE will be sent to the respective P-CSCF, hence not causing any ambiguity at the P-CSCF when forwarding the request via NAT.

---

## F.3 Void

## F.4 P-CSCF usage of SIP in case UDP encapsulated IPsec is not employed

### F.4.1 Introduction

The subclause F.4 describes the SIP procedures for supporting hosted NAT scenarios in case UDP encapsulated IPsec is not employed. In these scenarios the procedures for NAT traversal must take into account that all SIP requests and responses are not protected by an IPsec security association. This subclause also assumes that the UE transmits the SIP messages from the same IP address and port on which the UE expects to receive SIP messages.

### F.4.2 Registration

The procedures described in subclause 5.2.2 apply with the additional procedures described in the present clause.

When the P-CSCF receives a REGISTER request from the UE, the P-CSCF shall add the "received" header field parameter to the Via header field set to the source IP address of the packet header in accordance with the procedure defined in RFC 3261 [26] and RFC 3581 [56A]. If the "rport" header field parameter is included in the Via header field, the P-CSCF shall also set the value of the "rport" header field parameter to the source port of the request, in accordance with the procedure defined in RFC 3581 [56A].

When the P-CSCF detects that the UE is behind a NAT:

- if the UE has indicated in the received REGISTER request support of the keep-alive mechanism defined in SIP outbound (RFC 5626 [92]) according to RFC 6223 [143], the P-CSCF shall indicate to the UE that it supports the keep-alive mechanism; and
- if the UE has not indicated in the received REGISTER request support of the keep-alive mechanism defined in SIP outbound (RFC 5626 [92]) according to RFC 6223 [143]:
  - a) if a P-CSCF registration timer is running, the P-CSCF should not forward the REGISTER request if received half of the time before expiry of the S-CSCF registration timer, unless the request is intended to update the UE's capabilities according to RFC 3840 [62] or to modify the ICSI values or IARI values that the UE intends to use in the g.ims.app-ref feature tag. If the P-CSCF decides to not forward the REGISTER request, the P-CSCF shall build a 200 (OK) response based on the contents of the 200 (OK) response to the previous REGISTER request and send this response to the UE. If the P-CSCF decides to forward the REGISTER request, the P-CSCF shall set the registration expiration interval to the registration expiration interval value indicated in the received 200 (OK) response to the previous REGISTER request; and
  - b) when the P-CSCF receives a 200 (OK) response to the REGISTER request, the P-CSCF shall modify the value of the Expires header field and/or Expires parameter in the Contact header according to the transport protocol. In order to minimize the number of REGISTER requests to the S-CSCF, the P-CSCF may also start a P-CSCF registration timer with a value of 600 seconds if the value received from the S-CSCF was for greater than 1200 seconds, or to half of the time otherwise.

If, upon receiving a REGISTER request from an unregistered user and the P-CSCF discovers that the UE is behind a NAT, the P-CSCF performs the following actions on the Contact header field depending on its content:

- if the Contact header field contains a contact address in the form of an IP address (NOTE), the P-CSCF shall save (for the duration of the registration) this IP address (i.e. the private IP address of the UE) and associated port number (i.e. the private port of the UE) and bind them to the source IP address (i.e. the public IP address of the NAT) and the source port number (i.e. the port number of the NAT) of the IP packet that contained the REGISTER request and forward the REGISTER request;
- if the Contact header field contains more than one contact addresses in the form of an IP address, the P-CSCF shall apply the above procedure to one of those contact addresses by choosing the one with the highest qvalue parameter) and delete any other contact addresses containing an IP address. If the P-CSCF was unable to choose a contact address based on the qvalue, the P-CSCF shall choose one based on local policy and delete any other contact addresses containing an IP address.

NOTE: When the host parameter in the Contact address is in the form of a FQDN, the P-CSCF will resolve the given FQDN (by DNS lookup) to the IP address of the UE. When including the FQDN in the Contact header field the UE insures that the FQDN resolves to the IP address that the UE uses to send the REGISTER request.

When the P-CSCF received a response to the above request, the P-CSCF shall forward the response to the UE using the mechanisms described in RFC 3581 [56A]. In case UDP is used, the P-CSCF shall send the response to the IP address indicated in the "received" header field parameter and to the port indicated in the "rport" header field parameter of the Via header field in the response. If the REGISTER request received from the UE was received over a TCP connection, the P-CSCF shall send the response to the UE over the same TCP connection over which the request was received. The P-CSCF shall transmit the IP packet (containing the response) from the same IP address and port on which the REGISTER request was received.

## F.4.3 General treatment for all dialogs and standalone transactions excluding the REGISTER method

### F.4.3.1 Introduction

The procedures described in subclause 5.2.6 apply with the additional procedures described in subclause F.4.3.

### F.4.3.2 Request initiated by the UE

When the P-CSCF receives, from the UE that is behind a NAT, an initial request for a dialog or a request for a standalone transaction, the P-CSCF shall:

- a) if the "rport" header field parameter is included in the Via header field, set the value of the "rport" header field parameter in the Via header field to the source port of the received IP packet that contained the request;
  - aa) insert the "received" header field parameter in the Via header field containing the source IP address of the received IP packet (that contained the request), as defined in RFC-3581 [56A];
- b) if the request is a dialog-forming request that was received over UDP, bind the source IP address (i.e. the public IP address of the NAT) and associated source port number (i.e. the port number of the NAT) of the received IP packet (that contained the initial dialog-forming request) to:
  - the IP address (i.e. the private IP address of the UE) and associated port number (i.e. the private port of the UE) contained in the Contact header field of the received dialog-forming request, if the Contact header field contained an IP address and associated port number, and save the binding; or
  - the saved IP address (i.e. the private IP address of the UE) and associated port number (i.e. the private port of the UE) contained in the Contact header field of the REGISTER request, if the Contact header field of the received dialog-forming request contained a GRUU, and save the binding; and
- c) if the dialog-forming request was received over TCP connection, keep this TCP connection up during the entire duration of the dialog;

before forwarding the request, based on the topmost Route header field, in accordance with the procedures of RFC 3261 [26].

When the P-CSCF receives a response to the above request, the P-CSCF shall forward the response to the UE using the mechanisms described in RFC 3581 [56A]. In case UDP is used, the P-CSCF shall send the response to the IP address indicated in the "received" header field parameter and to the port indicated in the "rport" header field parameter of the Via header field of the response. If the dialog-forming request received from the UE was received over the TCP connection, the P-CSCF shall send the response to the UE over the same TCP connection over which the dialog-forming request was received. The P-CSCF shall transmit the IP packet (containing the response) from the same IP address and port on which the initial dialog-forming request was received.

For all subsequent requests belonging to the dialog, received from the UE, the P-CSCF shall:

- insert the "received" header field parameter in the Via header field as described in RFC 3261 [26];
- if the "rport" header field parameter is included in the Via header field, set the value of the "rport" header field parameter in the Via header field as defined in RFC 3581 [56A]; and
- forward the request as described in RFC 3261 [26].

For all subsequent responses belonging to the dialog, destined for the UE, the P-CSCF shall forward the responses using the "received" header field parameter and if UDP is used, set the value of the "rport" header field parameter in the Via header field of the response as defined in RFC 3581 [56A].

For all subsequent requests belonging to the dialog and destined for the UE (that contains the private IP address and associated private port number in the Request-URI), the P-CSCF shall send the requests to the UE either:

- over the TCP connection that was established when the initial INVITE request was received; or
- use UDP. When sending the request using UDP, the P-CSCF shall insert the request in an IP packet, and send the IP packet to the saved IP address (i.e. the public IP address of the NAT) and associated port number (i.e. the port number of the NAT). The P-CSCF shall transmit the IP packet (containing the request) from the same IP address and port on which the REGISTER request was received.

**NOTE:** When inserting its SIP URI in the Record-Route header field of the dialog-forming request received from the UE, the P-CSCF can include a pointer in the user part of its SIP URI that points to the saved binding used to route the in-dialog requests to the UE. The Route header field of the in-dialog requests will contain the respective pointer in the user part of the P-CSCF's SIP URI.

### F.4.3.3 Request terminated by the UE

When the P-CSCF receives an initial request for a dialog or a request for a standalone transaction destined for the UE (it contains the private IP address and associated private port number in the Request-URI), the P-CSCF shall send the requests to the UE either:

- over the TCP connection for the related registration or registration flow (if the multiple registrations mechanism is used), if available (e.g. TCP connection was established during the registration procedure); or
- use UDP. When sending the request using UDP, the P-CSCF shall send the request to the saved IP address (i.e. the public IP address of the NAT) and associated port number (i.e. the port number of the NAT) for the related registration or registration flow (if the multiple registrations mechanism is used) that is bound to the private IP address and associated private port number indicated in the Request-URI and saved during the registration procedure. The P-CSCF shall transmit the IP packet (containing the request) from the same IP address and port on which the REGISTER request was received.

**NOTE 1:** If the Contact bound to the terminating UE's registration state includes a transport=tcp URI parameter, for the terminating requests, the P-CSCF follows the procedures specified in RFC 3261 [26] subclause 7 and RFC 3263 [27A] subclause 4.1 for selection of the transport, which recommend to use the TCP connection.

For all subsequent requests belonging to the dialog that are received from the UE, the P-CSCF shall:

- insert the "received" header field parameter in the Via header field as defined in RFC 3261 [26];
- if the "rport" header field parameter is included in the Via header field, set the value of the "rport" header field parameter in the Via header field as defined in RFC 3581 [56A]; and
- forward the request as described in RFC 3261 [26].

For all subsequent responses belonging to the dialog, destined to the UE, the P-CSCF shall forward the responses using the "received" header field parameter and if UDP is used, set the value of the "rport" header field parameter in the Via header field of the response as defined in RFC 3581 [56A].

For all subsequent requests belonging to the dialog and destined for the UE (that contains the private IP address and associated private port number in the Request-URI), the P-CSCF shall send the requests to the UE either:

- over the TCP connection, if available; or
- use UDP. When sending the request using UDP, the P-CSCF shall insert the request in an IP packet, and send the IP packet to the saved IP address (i.e. the public IP address of the NAT) and associated port number (i.e. the port number of the NAT). The P-CSCF shall transmit the IP packet (containing the request) from the same IP address and port on which the REGISTER request was received.

NOTE 2: When inserting its SIP URI in the Record-Route header field in a response to the dialog-forming request received from the UE, the P-CSCF can include a pointer in the user part of its SIP URI that points to the saved binding used to route the in-dialog requests to the UE. The Route header field of the in-dialog requests will contain the respective pointer in the user part of the P-CSCF's SIP URI.

---

## F.5 NAT traversal for media flows

To allow the IMS access gateway to perform address latching, for a given UDP-based media stream, the UE shall use the same port number for sending and receiving packets.

To allow early media flows, the UE shall send keepalive messages for each UDP-based media stream as soon as an SDP offer or answer is received in order to allow the IMS access gateway to perform address latching before the call is established.

To keep NAT bindings and firewall pinholes open for the UDP-based media streams, and enable the IMS access gateway to perform address latching, the UE shall send keepalive messages for each media stream as defined in subclause K.5.2.1.

## Annex G (informative): Void

---

# Annex H (normative): IP-Connectivity Access Network specific concepts when using DOCSIS to access IM CN subsystem

## H.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is a DOCSIS cable access network.

DOCSIS (Data Over Cable Service Interface Specification) is a term referring to the ITU-T Recommendation J112 [87] Annex B standard for cable modem systems.

---

## H.2 DOCSIS aspects when connected to the IM CN subsystem

### H.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the DOCSIS cable access network to provide packet-mode communication between the UE and the IM CN subsystem.

From the perspective of the UE, the necessary IP-CAN bearer for signalling is transparently available to the UE.

The UE is not directly involved in requests for IP-CAN bearer(s) for media flow(s). The IM CN interacts with the PCRF in the DOCSIS IP-CAN to establish IP-CAN bearer(s) for media flow(s), on behalf of the UE.

### H.2.2 Procedures at the UE

#### H.2.2.1 Activation and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall perform a Network Attachment procedure as defined in the CableLabs PacketCable specifications PKT-TR-ARCH-FRM [88]. When using DOCSIS, both IPv4 and IPv6 UEs may access the IM CN subsystem. The procedures for P-CSCF discovery defined in subclause 9.2.1 of this document apply.

##### H.2.2.1A Modification of IP-CAN used for SIP signalling

Not applicable.

##### H.2.2.1B Re-establishment of the IP-CAN used for SIP signalling

Not applicable.

##### H.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure uses the keep-alive procedures described in RFC 6223 [143].

If the P-CSCF fails to respond to the keep-alive request the UE shall acquire a different P-CSCF address using any of the methods described in the subclause H.2.2.1 and perform an initial registration as specified in subclause 5.1.

## H.2.2.2 Void

## H.2.2.3 Void

## H.2.2.4 Void

## H.2.2.5 Handling of the IP-CAN for media

### H.2.2.5.1 General requirements

The UE does not directly request resources for media flow(s).

#### H.2.2.5.1A Activation or modification of IP-CAN for media by the UE

Not applicable.

#### H.2.2.5.1B Activation or modification of IP-CAN for media by the network

Not applicable.

#### H.2.2.5.1C Deactivation of IP-CAN for media

Not applicable.

### H.2.2.5.2 Special requirements applying to forked responses

The UE does not directly request resources for media flow(s). As a result there are no special UE requirements applying to forked responses.

### H.2.2.5.3 Unsuccessful situations

Not applicable.

## H.2.2.6 Emergency service

### H.2.2.6.1 General

If attached to network via DOCSIS access technology, the UE shall always consider being attached to its home operator's network for the purpose of emergency calls.

NOTE: In DOCSIS the UE is unable to receive any indication from the network, that would allow the UE to determine, whether it is currently attached to its home operator's network or to a different network, so the UE assumes itself always attached to the home operator's network when connected via DOCSIS access technology.

#### H.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### H.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

#### H.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### H.2.2.6.3 Current location discovery during an emergency call

Void.

### H.2A Usage of SDP

#### H.2A.0 General

Not applicable.

#### H.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

Not applicable.

#### H.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

#### H.2A.3 Emergency service

No additional procedures defined.

---

### H.3 Application usage of SIP

#### H.3.1 Procedures at the UE

##### H.3.1.0 Void

##### H.3.1.0a IMS\_Registration\_handling policy

Not applicable.

##### H.3.1.1 P-Access-Network-Info header field

If the UE is aware of the access technology, the UE shall include the P-Access-Network-Info header field where indicated in subclause 5.1.

##### H.3.1.1A Cellular-Network-Info header field

Not applicable.

### H.3.1.2 Availability for calls

Not applicable.

### H.3.1.2A Availability for SMS

Void.

### H.3.1.3 Authorization header field

When using SIP digest or SIP digest without TLS, the UE need not include an Authorization header field on sending a REGISTER request, as defined in subclause 5.1.1.2.1.

**NOTE:** In case the Authorization header field is absent, the mechanism only supports that one public user identity is associated with only one private user identity. The public user identity is set so that it is possible to derive the private user identity from the public user identity by removing SIP URI scheme and the following parts of the SIP URI if present: port number, URI parameters, and To header field parameters. Therefore, the public user identity used for registration in this case cannot be shared across multiple UEs. Deployment scenarios that require public user identities to be shared across multiple UEs that don't include an private user identity in the initial REGISTER request can be supported as follows:

- Assign each sharing UE a unique public user identity to be used for registration,
- Assign the shared public user identities to the implicit registration set of the unique registering public user identities assigned to each sharing UE.

### H.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### H.3.1.5 3GPP PS data off

Not applicable.

### H.3.1.6 Transport mechanisms

No additional requirements are defined.

### H.3.1.7 RLOS

Not applicable.

## H.3.2 Procedures at the P-CSCF

### H.3.2.0 Registration and authentication

Void.

### H.3.2.1 Determining network to which the originating user is attached

If the access-type field in the P-Access-Network-Info header field indicated DOCSIS access the P-CSCF shall assume that the initial request for a dialog or standalone transaction or an unknown method destined for a PSAP is initiated in the same country.

NOTE 1: If local policy does not require the insertion of P-Access-Network-Info header field in the P-CSCF even if it is missing in the received initial request, the P-CSCF can assume that the request is initiated by fixed broadband UE in the same country.

NOTE 2: If the network provided and UE provided P-Access-Network-Info header fields indicate different access types the P-CSCF ignores the information in either the network provided or the UE provided P-Access-Network-Info header field according to operator policy.

### H.3.2.2 Location information handling

Upon receipt of an initial request for a dialog or standalone transaction or an unknown method, the P-CSCF based on local policy may include a P-Access-Network-Info header field.

NOTE: The way the P-CSCF deduces that the request comes from a UE connected through DOCSIS access is implementation dependent.

#### H.3.2.3 Void

#### H.3.2.4 Void

#### H.3.2.5 Void

#### H.3.2.6 Resource sharing

Not applicable.

#### H.3.2.7 RLOS

Not applicable.

### H.3.3 Procedures at the S-CSCF

#### H.3.3.1 Notification of AS about registration status

Not applicable.

#### H.3.3.2 RLOS

Not applicable.

# Annex I (normative): Additional routing capabilities in support of traffics in IM CN subsystem

## I.1 Scope

Additional routing functionality is necessary for support of:

- transit traffic as operators may use the IM CN subsystem as a transit network to provide transit functionality for their own CS networks, enterprise networks, or other network operators;
- other traffics such as roaming traffic and incoming traffic destined to CSI UEs (Combining Circuit Switched (CS) and IP Multimedia Subsystem (IMS) services) traffics;
- traffic for the roaming architecture for voice over IMS with local breakout; and
- originating traffic if required by local policy as specified in subclause 5.4.3.2.

Depending on the additional routing functionalities, the required specific functions may reside in a stand-alone entity or may be collocated with an MGCF, a BGCF, an I-CSCF, an S-CSCF, or an IBCF as appropriate for the specific scenario.

When collocated with an I-CSCF, the additional routing capabilities may be performed in advance of I-CSCF procedures as specified in subclause 5.3, or after I-CSCF procedures have failed to identify an S-CSCF supporting the user identified by the Request-URI.

When collocated with an MGCF, the generated requests can be routed to an I-CSCF or to possible targets of the routing procedures defined in subclause I.2.

The BGCF procedures specified in subclause 5.6 are a subset of the more general routing procedures provided in this annex.

NOTE: Depending on the host entity for the additional routing functions, the functionality can be accessed as:

- a) the last set of functions on the host before forwarding a request (e.g., on an MGCF, an S-CSCF or an IBCF);
- b) the first set of functions performed by the host entity when receiving a request at the host entity's entry point (e.g., on a BGCF, I-CSCF or IBCF);
- c) a specified point in the logic of the host (e.g., on the I-CSCF at failure to identify an S-CSCF for the Request-URI); or
- d) a set of functions associated with a separate entry point (e.g., at a separate entry point associated with a BGCF, I-CSCF, IBCF or stand-alone entity).

---

### I.1A General

For all SIP transactions identified, if priority is supported, as containing an authorised Resource-Priority header field, or, if such an option is supported, relating to a dialog which previously contained an authorised Resource-Priority header field. The additional routing functionality shall give priority over other transactions or dialogs. This allows special treatment of such transactions or dialogs.

NOTE 1: The special treatment can include filtering, higher priority processing, routing, call gapping. The exact meaning of priority is not defined further in this document, but is left to national regulation and network configuration.

NOTE<sup>2</sup>: These SIP transactions are exempt from network management controls.

If logging is in progress for this dialog, check whether a trigger for stopping logging of SIP signalling has occurred, as described in RFC 8497 [140] and configured in the trace management object defined in 3GPP TS 24.323 [8K]. If a stop trigger event has occurred then stop logging of signalling, else determine, by checking its debug configuration, whether to log the response.

With the exception of 305 (Use Proxy) responses, the additional routing functionality shall not recurse on 3xx responses.

If the additional routing functionality inserts its own Record-Route header field, then the additional routing functionality may require the periodic refreshment of the session to avoid hung states. If the network element requires the session to be refreshed, the additional routing functionality shall apply the procedures described in RFC 4028 [58] clause 8.

NOTE 3: Requesting the session to be refreshed requires support by at least one of the UEs. This functionality cannot automatically be granted, i.e. at least one of the involved UEs needs to support it.

Based on local policy the additional routing function shall add in requests and in responses in the P-Charging-Vector header field a "transit-ioi" header field parameter with an entry which identifies the operator network which the request or response is transiting or with a void entry.

Based on local policy the additional routing function shall delete or void in requests and in responses in the P-Charging-Vector header field any received "transit-ioi" header field parameter value.

---

## 1.2 Originating, transit and interconnection routing procedures

The additional routing functionality, or associated functional entity, performing these additional routing procedures should analyse the destination address, and determine whether to route to another network, directly, or via the IBCF, or to the BGCF, the MGCF or the I-CSCF in its own network. This analysis may use public (e.g., DNS, ENUM) and/or private database lookups, and/or locally configured data and may, based on operator policy, modify the Request-URI (e.g. to remove number prefixes, to translate local numbers to global numbers, to update the Request-URI with the URI including an obtained ported-to routing number, etc).

In addition, and based upon local policy, the analysis may include the carrier identified by the "cic" tel-URI parameter of the Request-URI and other signalling information from the incoming request as part of the route determination. Examples of other signalling information are: the content of the P-Access-Network-Info header field, the value of the "cpc" tel URI parameter of the P-Asserted-Identity header field, the value of the "phone-context" Tel URI parameter of the Request-URI, the SDP content, the ICSI values in the Contact header field and the content of the P-Asserted-Service header field.

If the additional routing functionality decides that the request shall be routed via a specific entity (e.g. IBCF), it shall insert the URI of this entity in the Route header of the request.

When provided as a stand-alone entity, the network element performing these functions need not Record-Route the INVITE request.

When provided as a stand-alone entity, the network element performing these functions shall not apply the procedures of RFC 3323 [33] relating to privacy.

If overlap signalling using the multiple-INVITE method is supported as a network option, several INVITE requests with the same Call ID and same From header field (including "tag" header field parameter) can be received outside of an existing dialog. Such INVITE requests relate to the same call and the additional routing function shall route such INVITE request received during a certain period of time to the same next hop.

When colocated with a MGCF, based on local policy for calls originated from circuit-switched networks, if the circuit-switched is a transit network the additional routing function shall add in requests in the P-Charging-Vector header field a "transit-ioi" header field parameter with an entry which identifies the PSTN network which the request was transiting or with a void entry.

NOTE 1: Only one "transit-ioi" header field parameter entry is added per transit network.

NOTE 2: The local policy can take bilateral agreements between operators into consideration.

The entity implementing the additional routeing functionality shall remove the P-Served-User header field prior to forwarding the request.

If

- a) the additional routeing functionality supports indicating the traffic leg as specified in RFC 7549 [225];
- b) the Request-URI does not already include an "iotl" SIP URI parameter, and

NOTE 3: If an "iotl" SIP URI parameter is included it contains the value "visitedA-homeB" inserted by the TRF in the roaming architecture for voice over IMS with local breakout scenario.

- c) required by local policy;

then the additional routeing functionality shall:

- a) if the Request-URI contains a SIP URI, append the "iotl" SIP URI parameter set to "homeA-homeB" to the Request-URI; and
- b) if the Request-URI contains a tel URI:
  - convert the tel URI in the Request-URI to the form of a SIP URI with user=phone; and
  - append an "iotl" SIP URI parameter with a value set to "homeA-homeB" in the Request-URI.

---

## 1.3 Providing IMS application services in support of transit & interconnection traffics

### 1.3.1 Introduction

When the IM CN subsystem provides transit functionality to other operator networks or enterprise networks, it may also provide IMS applications services to the operator network or enterprise network.

The transit service invocation, performed by a transit function, is performed based on local configured transit invocation criteria that are provided for the specific transit scenario.

NOTE: The transit invocation criteria for invocation is intended to be per served network basis, for which transit functionality is provided, and not per subscriber basis.

Similar to the initial filter criteria for a user profile, the transit invocation criteria may have service point triggers, used to generate an ordered list of transit invocation criteria to be applied to a request, based on different information in the request, SIP method, SIP header field, and SIP body. The service invocation procedure shall support suppression/avoidance of conflicting services, multiple invocations of the same service and loopback scenarios.

### 1.3.2 Procedures

#### 1.3.2.1 Treatment for dialog and standalone transactions

When the transit function receives an initial request for a dialog, or a request for a standalone transaction, and the request is received either from a functional entity within the same trust domain or contains a valid original dialog identifier (see step 3) or the dialog identifier (From, To and Call-ID header fields) relates to an existing request processed by the transit function, then prior to forwarding the request, the transit function shall:

- 1) check if an original dialog identifier that the transit function previously placed in a Route header field is present in the topmost Route header field of the incoming request.
  - If not present, the transit function shall build an ordered list of transit invocation criteria.

- If present, the request has been sent from an AS in response to a previously sent request, an ordered list of transit invocation criteria already exists and the transit function shall not change the ordered list of transit invocation criteria.

- 2) remove its own SIP URI from the topmost Route header field;
- 3) check whether the initial request matches any unexecuted transit invocation criteria. If there is a match, then the transit function shall select the first matching unexecuted transit invocation criteria from the ordered list of transit invocation criteria and the transit function shall insert the AS URI to be contacted into the Route header field as the topmost entry followed by its own URI populated;

NOTE: Depending on the result of processing the transit invocation criteria the transit function can contact one or more AS(s) before processing the outgoing Request-URI.

- 4) if the request is not forwarded to an AS and if local policy requires the application of other additional routing capabilities, handled by entities other than the transit function, the transit function shall apply the additional routing capabilities if they are locally available or forward the request to an entity that implements the additional routing capabilities;
- 5) determine the destination address (e.g. DNS access) using the URI placed in the topmost Route header field if present, otherwise based on the Request-URI. If the destination requires interconnect functionalities (e.g. the destination address is of an IP address type other than the IP address type used in the IM CN subsystem), the transit function shall forward the request to the destination address via an IBCF in the same network;
- 6) in case of an initial request for a dialog, based on local policy record-route; and
- 7) route the request based on SIP routing procedures.

When the transit function receives a target refresh request, or a subsequent request other than target refresh request, for a dialog, prior to forwarding the request, the transit function shall:

- 1) remove its own URI from the topmost Route header field; and
- 2) forward the request based on the topmost Route header field.

With the exception of 305 (Use Proxy) responses, the transit function shall not recurse on 3xx responses.

### 1.3.2.1A Handling of header fields related to charging

When the transit function receives a request from a functional entity that is not an AS and if the request is forwarded to an AS the transit function shall:

- store the value of the "orig-ioi" header field parameter received in the P-Charging-Vector header field if present;

NOTE 1: Any received "orig-ioi" header field parameter will be a type 2 IOI. The type 2 IOI identifies the service provider from which the request was sent.

- remove the "orig-ioi" header field parameter from the P-Charging-Vector header field, if present;
- store the value of the "transit-ioi" header field parameter and remove the "transit-ioi" header field parameter, if present; and
- insert in the P-Charging-Vector header field an IOI type 3 value in an "orig-ioi" header field parameter identifying the network sending the request and based on operator option a Relayed-Charge header field with contents set to the value of the received "transit-ioi" header field parameter.

When forwarding the request from an AS to a functional entity that is not an AS the transit function shall:

- store the value of the "orig-ioi" header field parameter received in the P-Charging-Vector header field if present;

NOTE 2: Any received "orig-ioi" header field parameter will be a type 3 IOI. The type 3 IOI identifies the service provider from which the request was sent.

- remove the "orig-ioi" header field parameter from the P-Charging-Vector header field, if present; and

- insert in the P-Charging-Vector header field the "orig-ioi" header field parameter with the IOI type 2 value stored when the initial request for a dialog or the request for a standalone transaction was received from an entity that was not an AS;
- insert the "transit-ioi" header field parameter if previously stored; and
- remove the Relayed-Charge header field, if present.

When the transit function receives a 1xx or 2xx response to a request from a functional entity that is not an AS and if the response is forwarded to an AS the transit function shall:

- store the values of the "orig-ioi", the "term-ioi" and the "transit-ioi" header field parameter received in the P-Charging-Vector header field if present;

NOTE 3: Any received "term-ioi" header field parameter will be a type 2 IOI. The type 2 IOI identifies the service provider from which the response was sent.

- remove the "orig-ioi", the "term-ioi", and the "transit-ioi" header field parameters from the P-Charging-Vector header field, if present; and
- insert in the P-Charging-Vector header field an IOI type 3 value in a "term-ioi" header field parameter identifying the network sending the response, an IOI type 3 value in an "orig-ioi" header field parameter stored when the request was received from an AS, and based on operator option a Relayed-Charge header field with contents set to the value of the received "transit-ioi" header field parameter.

When forwarding any response to a request from an AS to a functional entity that is not an AS the transit function shall remove the Relayed-Charge header field, if present.

When forwarding the 1xx or 2xx response to a request from an AS to a functional entity that is not an AS the transit function shall:

- remove the "orig-ioi" and the "term-ioi" header field parameter from the P-Charging-Vector header field, if present; and

NOTE 4: Any received "term-ioi" and "orig-ioi" header field parameter will be a type 3 IOI. The type 3 IOI identifies the service provider from which the response was sent.

- insert in the P-Charging-Vector header field an "orig-ioi" header field parameter with the IOI type 2 value, an "term-ioi" header field parameter with the IOI type 2 value received in the 1xx or 2xx response to the request from a functional entity that was not an AS, insert the "transit-ioi" header field parameter if previously stored.

### 1.3.2.2 Original dialog identifier for transit function

The original dialog identifier is an implementation specific token that the transit function encodes into the own transit function URI in a Route header field, prior to forwarding the request to an AS. This is possible because the transit function is the only entity that creates and consumes the value.

The token may identify the original dialog of the request, so in case an AS acting as a B2BUA changes the dialog, the transit function is able to identify the original dialog when the request returns to the transit function. In a case of a standalone transaction, the token indicates that the request has been sent to the transit function from an AS in response to a previously sent request. The token can be encoded in different ways, such as e.g., a character string in the user-part of the transit function URI, a parameter in the transit function URI or port number in the transit function URI.

The transit function shall ensure that the value chosen is unique, in order for the transit function to recognize the value when received in a subsequent message of one or more dialogs and make the proper association between related dialogs that pass through an AS.

An original dialog identifier is sent to each AS invoked due to transit invocation criteria evaluation such that the transit function can associate requests as part of the same sequence that trigger transit invocation criteria evaluation in priority order (and not rely on SIP dialog information that may change due to B2BUA AS).

- NOTE: If the same original dialog identifier is included in more than one request from a particular AS (based on service logic in the AS), then the transit function will continue the transit invocation criteria evaluation sequence. If the AS wants transit invocation criteria evaluation to start from the beginning for a request, then AS does not include an original dialog identifier.

## 1.4 Loopback routing procedures

### 1.4.1 Introduction

In order to support traffics for the roaming architecture for voice over IMS with local breakout the additional routing functionality will perform the procedures described in this subclause. An additional routing functionality performing the procedures in this subclause is always located in the visited PLMN and is referred to as Transit and Roaming Function (TRF).

The TRF performs local break out and routes the INVITE request via a specific entity e.g. IBCF or BGCF.

Loopback routing requires support in the visited network and the home network. If the visited network supports loopback routing then the P-CSCF will, based on local policy, express this support by adding a `g.3gpp.trf` feature-capability indicator value to the URI of the desired TRF.

The home network decides based on local operator policy if loopback routing shall be applied. If loopback routing is applied, the home network routes the INVITE request back to the TRF located in the visited network indicating that loopback routing is used by including the `g.3gpp.loopback` feature-capability indicator in a Feature-Caps header field.

In the loopback scenario OMR as specified in 3GPP TS 29.079 [11D] is used to determine the optimal media path between the visited network and the terminating network without passing through the home network.

### 1.4.2 TRF procedure

When the TRF receives an initial request for a dialog, the TRF shall:

- 1) retain the "icid-value" header field parameter in the P-Charging-Vector header field;
- 2) store the value of the "orig-ioi" header field parameter received in the P-Charging-Vector header field, if present, and remove the "orig-ioi" header field parameter from the P-Charging-Vector header field. Insert a type 2 "orig-ioi" header field parameter into the P-Charging-Vector header field. Set the type 2 "orig-ioi" header field parameter to a value that identifies the sending network in which the TRF resides. The TRF shall not include the "term-ioi" header field parameter. Store the value of a "transit-ioi" header field parameter received in the P-Charging-Vector header field, if present, and remove the "transit-ioi" header field parameter from the P-Charging-Vector header field before forwarding the request;
- 3) if required by local policy, perform number normalization and enum translation in the same way as performed by S-CSCF in subclause 5.4.3.2 step 10);
- 4) if the P-Access-Network header field is available, determine the entity for local break out (e.g. IBCF or BGCF) using:
  - a) the location of the originating user; and
  - b) the destination address,then include a Route header field set to the URI associated with the determined entity in the forwarded request;
- 5) create a Record-Route header field containing the TRF own SIP URI;
- 6) remove the "+g.3gpp.loopback" header field parameter from the Feature-Caps header field of the outgoing request;
- 6A) if the TRF supports indicating the traffic leg as specified in RFC 7549 [225] and required by local policy:
  - a) if the Request-URI in the INVITE request contains a SIP URI, append an "iotl" SIP URI parameter set to "visitedA-homeB" to the Request-URI; and
  - b) if the Request-URI in the INVITE request contains a tel URI:
    - convert the tel URI in the Request-URI to the form of a SIP URI with user=phone; and

- append the "iotl" SIP URI parameter set to "visitedA-homeB" in the Request-URI; and

7) route the request based on SIP routing procedures.

When the TRF receives a 1xx or 2xx response to the INVITE request above, the TRF shall:

- store the value of the "transit-ioi" header field parameter received in the P-Charging-Vector header field and remove the "transit-ioi" header field parameter from the P-Charging-Vector header field, if present;
- remove the "orig-ioi" header field parameter and the "term-ioi" header field parameter from the P-Charging-Vector header field before forwarding the response; and

NOTE: Any received "term-ioi" header field parameter will be a type 2 IOI identifying the sending network of the response.

- insert in the P-Charging-Vector header field the "orig-ioi" header field parameter, if received in the request, and the type 1 "term-ioi" header field parameter in the response. The TRF shall set the type 1 "term-ioi" header field parameter to a value that identifies the network in which the TRF resides and the type 1 "orig-ioi" header field parameter is set to the previously received value of the type 1 "orig-ioi" header field parameter.

When the TRF receives subsequent requests or responses to subsequent requests containing the "+g.3gpp.loopback" header field parameter from the Feature-Caps header field, the TRF shall remove the "+g.3gpp.loopback" header field parameter from the Feature-Caps header field of the outgoing request or the outgoing response.

When the TRF receives responses to initial or subsequent requests from the terminating side, the TRF shall insert in the P-Charging-Vector header field, if present, the "loopback" header field parameter to the outgoing response.

When the TRF receives subsequent requests from the terminating side, the TRF shall insert in the P-Charging-Vector header field, if present, the "loopback" header field parameter to the outgoing request.

When the TRF receives a subsequent request, the TRF shall:

- 1) retain the "icid-value" header field parameter in the P-Charging-Vector header field;
- 2) store the value of the "orig-ioi" header field parameter received in the P-Charging-Vector header field, if present, and remove the "orig-ioi" header field parameter from the P-Charging-Vector header field;
- 3) if the subsequent request is:
  - a) received from originating home network and forwarded to terminating home network, insert a type 2 "orig-ioi" header field parameter into the P-Charging-Vector header field, and set the type 2 "orig-ioi" header field parameter to a value that identifies the sending network in which the TRF resides. The TRF shall not include the "term-ioi" header field parameter; or
  - b) received from terminating home network and forwarded to originating home network, insert a type 1 "orig-ioi" header field parameter into the P-Charging-Vector header field, and set the type 1 "orig-ioi" header field parameter to a value that identifies the sending network in which the TRF resides. The TRF shall not include the "term-ioi" header field parameter; and
- 4) store the value of a "transit-ioi" header field parameter received in the P-Charging-Vector header field, if present, and remove the "transit-ioi" header field parameter from the P-Charging-Vector header field before forwarding the request.

When the TRF receives a response to a subsequent request, the TRF shall:

- 1) store the value of the "transit-ioi" header field parameter received in the P-Charging-Vector header field and remove the "transit-ioi" header field parameter from the P-Charging-Vector header field, if present;
- 2) remove the "orig-ioi" header field parameter and the "term-ioi" header field parameter from the P-Charging-Vector header field before forwarding the response; and
- 3) if the response to the subsequent request is:
  - a) received from terminating home network and forwarded to originating home network, insert in the P-Charging-Vector header field the "orig-ioi" header field parameter, if received in the request, and the type 1 "term-ioi" header field parameter in the response. The TRF shall set the type 1 "term-ioi" header field

parameter to a value that identifies the network in which the TRF resides and the type 1 "orig-ioi" header field parameter is set to the previously received value of the type 1 "orig-ioi" header field parameter; and

- b) received from originating home network and forwarded to terminating home network, insert in the P-Charging-Vector header field the "orig-ioi" header field parameter, if received in the request, and the type 2 "term-ioi" header field parameter in the response. The TRF shall set the type 2 "term-ioi" header field parameter to a value that identifies the network in which the TRF resides and the type 2 "orig-ioi" header field parameter is set to the previously received value of the type 2 "orig-ioi" header field parameter.

---

## 1.5 Overload control

### 1.5.1 Introduction

The additional routing functionality, or associated functional entity, performing additional routing procedures described in I.3 may support the event-based overload control mechanism.

### 1.5.2 Outgoing subscriptions to load-control event

Based on operator policy, the additional routing functionality may subscribe to the load-control event package with one or more target SIP entities. The list of target SIP entities is provisioned.

Subscription to the load-control event package is triggered by internal events (e.g. the physical device hosting the SIP entity is power-cycled) or through a management interface.

The AS shall perform subscriptions to the load-control event package to a target entity in accordance with RFC 6665 [28] and with RFC 7200 [201]. When subscribing to the load-control event, additional routing functionality shall:

- 1) Send a SUBSCRIBE request in accordance with RFC 6665 [28] and with RFC 7200 [201] to the target entity, with the following elements:
  - an Expires header field set to a network specific value;
- 2) If the target entity is located in a different network and local policy requires the application of IBCF capabilities, forward the request to an IBCF acting as an exit point.

The additional routing functionality shall automatically refresh ongoing subscriptions to the load-control event package either 600 seconds before the expiration time if the initial subscription was for greater than 1200 seconds, or when half of the time has expired if the initial subscription was for 1200 seconds or less.

The additional routing functionality can terminate a subscription according to RFC 6665 [28].

# Annex J (normative): Void

---

# Annex K (normative): Additional procedures in support of UE managed NAT traversal

## K.1 Scope

This annex describes the UE, P-CSCF, and S-CSCF procedures in support of UE managed NAT traversal. For ICE, the IBCF procedures are also described. In this scenario, both the media flows and the SIP signalling both traverse a NA(P)T device located in the customer premises domain. The term "hosted NAT" is used to address this function. This annex does not consider the case where the NAT is behind the P-CSCF as different NAT traversal procedures are necessary for this architectural scenario.

The procedures described in this subclause of this annex rely on the UE to manage the NAT traversal process. As part of the UE management process, the UE can learn whether it is behind a NAT or not, and choose whether the procedures in this annex are applied or not.

The protection of SIP messages is provided by applying either UDP encapsulation to IPSec packets in accordance with RFC 3948 [63A] and as defined in 3GPP TS 33.203 [19] or by utilizing TLS as defined in 3GPP TS 33.203 [19].

NOTE 1: This annex describes the mechanism for support of UE managed NAT traversal scenario defined in 3GPP TS 23.228 [7]. This does not preclude other mechanisms but they are out of the scope of this annex.

NOTE 2: It is recognized that outbound can be useful for capabilities beyond NAT traversal (e.g. multiple registrations) however this annex does not consider such capabilities at this time. Such capabilities can require additional information elements in the REGISTER request so that the P-CSCF and S-CSCF can distinguish whether to apply procedures as of annex F or annex K.

---

## K.2 Application usage of SIP

### K.2.1 Procedures at the UE

#### K.2.1.1 General

This subclause describes the UE SIP procedures for supporting a UE managed hosted NAT traversal approach. The description enhances the procedures specified in subclause 5.1.

#### K.2.1.2 Registration and authentication

##### K.2.1.2.1 General

The text in subclause 5.1.1.1 applies without changes.

##### K.2.1.2.1A Parameters contained in the ISIM

The text in subclause 5.1.1.1A applies without changes.

##### K.2.1.2.1B Parameters provisioned to a UE without ISIM or USIM

The text in subclause 5.1.1.1B applies without changes.

## K.2.1.2.2 Initial registration

### K.2.1.2.2.1 General

The procedures described in subclause 5.1.1.2.1 apply with the additional procedures described in the present subclause.

NOTE 1: In accordance with the definitions given in subclause 3.1 the IP address acquired initially by the UE in a hosted NAT scenario is the UE private IP address.

On sending a REGISTER request, the UE shall populate the header fields as indicated in subitems a) through j) of subclause 5.1.1.2 with the exceptions of subitems c) and d) which are modified as follows.

The UE shall populate:

- c) a Contact header field according to the following rules: the Contact header field shall be set to include SIP URI(s) containing the private IP address or FQDN of the UE in the hostport parameter. The UE shall also include an instance ID ("sip.instance" header field parameter) and "reg-id" header field parameter as described in RFC 5626 [92]. The UE shall include all supported ICSI values (coded as specified in subclause 7.2A.8.2) in a g.3gpp.icsi-ref media feature tag as defined in subclause 7.9.2 and RFC 3840 [62] for the IMS communication services it intends to use, and IARI values (coded as specified in subclause 7.2A.9.2), for the IMS applications it intends to use in a g.3gpp.iari-ref media feature tag as defined in subclause 7.9.3 and RFC 3840 [62];
- d) a Via header field set to include the private IP address or FQDN of the UE in the sent-by field. For TCP, the response is received on the TCP connection on which the request was sent. For UDP, the UE shall include the "rport" header field parameter as defined in RFC 3581 [56A].

NOTE 2: The UE will learn its public IP address from the "received" header field parameter in the topmost Via header field in the 401 (Unauthorized) response to the unprotected REGISTER request.

NOTE 3: If the UE specifies a FQDN in the hostport parameter in the Contact header field and in the sent-by field in the Via header field of an unprotected REGISTER request, this FQDN will not be subject to any processing by the P-CSCF or other IMS entities.

When a 401 (Unauthorized) response to a REGISTER request is received with integrity protection the UE shall behave as described in subclause K.2.1.2.5.

When a 401 (Unauthorized) response to a REGISTER request is received and this response is received without integrity protection, the procedures described in subclause 5.1.1.2 apply with the following additions:

The UE shall compare the IP address in the "received" header field parameter with the corresponding value in the sent-by parameter in the topmost Via header field to detect if the UE is behind a NAT. If the comparison indicates that the respective values are the same, the UE concludes that it is not behind a NAT.

- if the UE is not behind a NAT the UE shall proceed with the procedures described in subclause 5.1;
- if the UE is behind a NAT the UE shall verify using the Security-Server header field that either the mechanism-name "tls" or "ipsec-3gpp" and the mode "UDP-enc-tun" is selected. If the verification succeeds the UE shall behave as described in subclause K.2.1.2.5 and store the IP address contained in the "received" header field parameter as the UE's public IP address. If the verification does not succeed the UE shall abort the registration.

On receiving the 200 (OK) response to the REGISTER request, the procedures described in subclause 5.1.1.2 apply with the following additions:

The UE shall determine the P-CSCFs ability to support the keep-alive procedures as described in RFC 5626 [92] by checking whether the "outbound" option-tag is present in the Require header field:

- if no "outbound" option-tag is present, the UE may use some other explicit indication in order to find out whether the P-CSCF supports the outbound edge proxy functionality. Such indication may be accomplished either through UE local configuration means or the UE can examine the 200 (OK) response to its REGISTER request for Path header fields, and if such are present check whether the bottommost Path header field contains the "ob" SIP URI parameter. If the UE determines that the P-CSCF supports the outbound edge proxy functionality, the UE can use the keep-alive techniques defined in subclause K.2.1.5 and RFC 5626 [92] towards the P-CSCF; or
- if an "outbound" option-tag is present, the UE shall initiate keep-alive mechanisms as defined in subclause K.2.1.5 and RFC 5626 [92] towards the P-CSCF.

NOTE 4: Presence of the "outbound" option-tag in the Require header field indicates that both the P-CSCF and S-CSCF fully support the outbound procedures. The number of subsequent outbound registrations for the same private user identity but with a different reg-id value is based on operator policy.

#### K.2.1.2.2.2 Initial registration using IMS AKA

The procedures described in subclause 5.1.1.2.2 apply with the additional procedures described in the present subclause.

On sending a REGISTER request, the UE shall populate the header fields as indicated in subclause 5.1.1.2.2 with the exceptions of the subitems which are modified as follows:

- c) additionally for the Via header field, for UDP, if the REGISTER request is protected by a security association, include the public IP address or FQDN and the protected server port value in the sent-by field. For TCP, if the REGISTER request is protected by a security association, the UE shall include the public IP address or FQDN;
- d) the Security-Client header field set to specify the security mechanisms the UE supports, the IPsec layer algorithms the UE supports and the parameters needed for the security association setup. The UE shall support the setup of two pairs of security associations as defined in 3GPP TS 33.203 [19]. The syntax of the parameters needed for the security association setup is specified in annex H of 3GPP TS 33.203 [19]. The UE shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The UE shall support the IPsec layer algorithms for integrity and confidentiality protection as defined in 3GPP TS 33.203 [19], and shall announce support for them according to the procedures defined in RFC 3329 [48]. In addition to transport mode, the UE shall support UDP encapsulated tunnel mode as per RFC 3948 [73A] and shall announce support for both modes as described in 3GPP TS 33.203 [19];

#### K.2.1.2.2.3 Initial registration using SIP digest without TLS

The procedures described in subclause 5.1.1.2.3 apply without modification.

#### K.2.1.2.2.4 Initial registration using SIP digest with TLS

The procedures described in subclause 5.1.1.2.4 apply without modification.

#### K.2.1.2.2.5 Initial registration using NASS-IMS bundled authentication

The procedures described in subclause 5.1.1.2.5 apply without modification.

#### K.2.1.2.3 Initial subscription to the registration-state event package

The procedures described in subclause 5.1.1.3 apply with the additional procedures described in subclause K.2.1.4.1.

#### K.2.1.2.4 User-initiated re-registration

##### K.2.1.2.4.1 General

The procedures described in subclause 5.1.1.4 apply with the additional procedures described in the present subclause.

On sending a REGISTER request that does not contain a challenge response, the UE shall populate the header fields as indicated in subclause 5.1.1.4.1 with the exception of subitems c) and d) which are modified as follows.

The UE shall populate:

- c) a Contact header field set to include SIP URI(s) that contain(s) in the hostport parameter the private IP address of the UE or FQDN, its instance ID ("sip.instance" header field parameter) along with the same "reg-id" header field parameter used for the initial, successful, registration for the given P-CSCF public identity combination as described in RFC 5626 [92]. The UE shall include all supported ICSI values (coded as specified in subclause 7.2A.8.2) in a g.3gpp.icsi-ref media feature tag as defined in subclause 7.9.2 and RFC 3840 [62] for the IMS communication services it intends to use, and IARI values (coded as specified in subclause 7.2A.9.2), for the IMS applications it intends to use in a g.3gpp.iari-ref media feature tag as defined in subclause 7.9.3 and RFC 3840 [62]; and

d) a Via header field according to the following rules:

- For UDP, the UE shall include the public IP address or FQDN in the sent-by field. The UE shall also include the "rport" header field parameter as defined in RFC 3581 [56A]. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT; or
- For TCP, the UE shall include the public IP address or FQDN of the UE in the sent-by field. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT;

When the timer F expires at the UE, the UE shall:

- 1) stop processing of all ongoing dialogs and transactions associated with that, if any (i.e. no further SIP signalling will be sent by the UE on behalf of these transactions or dialogs); and
- 2) after releasing all IP-CAN bearers used for the transport of media according to the procedures in subclause 9.2.2, the UE shall follow the procedures in RFC 5626 [92] to form a new flow to replace the failed one. When registering to create a new flow to replace the failed one, procedures in subclause 5.1.1.2 apply.

NOTE: These actions can also be triggered as a result of the failure of a STUN keep-alive. It is an implementation option whether these actions are also triggered by other means than expiration of timer F, e.g., based on ICMP messages.

If failed registration attempts occur in the process of creating a new flow, the flow recovery procedures defined in RFC 5626 [92] shall apply.

#### K.2.1.2.4.2 IMS AKA as a security mechanism

The procedures described in subclause 5.1.1.4.2 apply without modification.

#### K.2.1.2.4.3 SIP Digest without TLS as a security mechanism

The procedures described in subclause 5.1.1.4.3 apply without modification.

#### K.2.1.2.4.4 SIP Digest with TLS as a security mechanism

The procedures described in subclause 5.1.1.4.4 apply without modification.

#### K.2.1.2.4.5 NASS-IMS bundled authentication as a security mechanism

The procedures described in subclause 5.1.1.4.5 apply without modification.

### K.2.1.2.5 Authentication

#### K.2.1.2.5.1 IMS AKA – general

The procedures of subclause 5.1.1.5.1 apply with the additional procedures described in the present subclause.

On receiving a 401 (Unauthorized) response to the REGISTER request and the response is deemed to be valid and signalling security is to be used, the UE shall behave as of subclause 5.1.1.5.1 with the exception of subitem 3) which is modified as follows.

The UE shall:

- 3) send another REGISTER request using the temporary set of security associations to protect the message. The header fields are populated as defined for the initial registration (see subclause K.2.1.2.2), with the addition that the UE shall include an Authorization header field containing the private user identity and if the "algorithm" header field parameter is "AKAv1-MD5", the authentication challenge response shall be calculated by the UE using RES and other parameters, as described in RFC 3310 [49]. If the "algorithm" header field parameter is "MD5", the UE shall calculate SIP digest-response parameters as indicated in RFC 2617 [21] and shall build an Authorization header field based on these parameters. The UE shall also insert the Security-Client header field that is identical to the Security-Client header field that was included in the previous REGISTER request (i.e. the REGISTER request that was challenged with the received 401 (Unauthorized) response). The UE shall also

insert the Security-Verify header field into the request, by mirroring in it the content of the Security-Server header field received in the 401 (Unauthorized) response. The UE shall set the Call-ID of the integrity-protected REGISTER request which carries the authentication challenge response to the same value as the Call-ID of the 401 (Unauthorized) response which carried the challenge.

For IPsec, if the 200 (OK) response is not received before the temporary SIP level lifetime of the temporary set of security associations expires or a 403 (Forbidden) response is received, the UE shall consider the registration to have failed. The UE shall delete the temporary set of security associations it was trying to establish, and use the old set of security associations. The UE should send an unprotected REGISTER request according to the procedure specified in subclause K.2.1.2.2 if the UE considers the old set of security associations to be no longer active at the P-CSCF.

#### K.2.1.2.5.2 Void

#### K.2.1.2.5.3 IMS AKA abnormal cases

The text in subclause 5.1.1.5.3 applies without changes.

#### K.2.1.2.5.4 SIP digest without TLS – general

The text in subclause 5.1.1.5.4 applies without changes.

#### K.2.1.2.5.5 SIP digest without TLS – abnormal procedures

The procedures of subclause 5.1.1.5.5 apply with the additional procedures described in the present subclause.

On receiving a 403 (Forbidden) response, the UE shall consider the registration to have failed. If performing SIP digest with TLS, the UE should send an initial REGISTER according to the procedure specified in subclause K.2.1.2.2 if the UE considers the TLS session to be no longer active at the P-CSCF.

#### K.2.1.2.5.6 SIP digest with TLS – general

The text in subclause 5.1.1.5.6 applies without changes.

#### K.2.1.2.5.7 SIP digest with TLS – abnormal procedures

The text in subclause 5.1.1.5.7 applies without changes.

#### K.2.1.2.5.8 NASS-IMS bundled authentication – general

The text in subclause 5.1.1.5.8 applies without changes.

#### K.2.1.2.5.9 NASS-IMS bundled authentication – abnormal procedures

The text in subclause 5.1.1.5.9 applies without changes.

#### K.2.1.2.5.10 Abnormal procedures for all security mechanisms

The text in subclause 5.1.1.5.10 applies without changes.

#### K.2.1.2.5A Network initiated re-authentication

The procedures of subclause 5.1.1.5A apply with the additional procedures described in the present subclause.

On starting the re-authentication procedure sending a REGISTER request that does not contain a challenge response, the UE shall behave as of subclause 5.1.1.5A with the exception of subitem 2) which is modified as follows.

The UE shall:

- 2) start the re-authentication procedures at the appropriate time (as a result of the S-CSCF procedure described in subclause 5.4.1.6) by initiating a re-registration as described in subclause K.2.1.2.4, if required.

### K.2.1.2.5B Change of IPv6 address due to privacy

The text in subclause 5.1.1.5B applies without changes.

### K.2.1.2.6 User-initiated deregistration

#### K.2.1.2.6.1 General

The procedures of subclause 5.1.1.6.1 apply with the additional procedures described in the present subclause.

On sending a REGISTER request, the UE shall populate the header fields as indicated in subclause 5.1.1.6.1 with the exception of subitems c) and d) which are modified as follows.

The UE shall populate:

- c) a Contact header field set to either the value of "\*" or SIP URI(s) that contain(s) in the hostport parameter the IP address of the UE or FQDN, its instance ID ("sip.instance" header field parameter) along with the same "reg-id" header field parameter used for the initial, successful, registration for the given P-CSCF public identity combination as described in RFC 5626 [92];. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT;
- d) a Via header field according to the following rules:
  - For UDP, the UE shall include the public IP address or FQDN. The UE shall also include the "rport" header field parameter as defined in RFC 3581 [56A]. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT; or
  - For TCP, the UE shall include the public IP address or FQDN of the UE in the sent-by field. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT;

NOTE: In case of hosted NAT traversal only the UE public IP addresses are bound to security associations or TLS session.

#### K.2.1.2.6.2 IMS AKA as a security mechanism

The text in subclause 5.1.1.6.2 applies without changes.

#### K.2.1.2.6.3 SIP digest as a security mechanism

The text in subclause 5.1.1.6.3 applies without changes.

#### K.2.1.2.6.4 SIP digest with TLS as a security mechanism

The text in subclause 5.1.1.6.4 applies without changes.

#### K.2.1.2.6.5 Initial registration using NASS-IMS bundled authentication

The text in subclause 5.1.1.6.5 applies without changes.

### K.2.1.2.7 Network-initiated deregistration

The procedures of subclause 5.1.1.7 apply with the additional procedures described in the present subclause.

Upon receipt of a NOTIFY request on the dialog which was generated during subscription to the reg event package as described in subclause 5.1.1.3, including one or more <registration> element(s) which were registered by this UE with:

- the state attribute set to "terminated" and the event attribute set to "rejected" or "deactivated"; or
- the state attribute set to "active" and the state attribute within the <contact> element belonging to this UE set to "terminated", and associated event attribute element to "rejected" or "deactivated";

The UE shall remove all registration details relating to these public user identities. In case of a "deactivated" event attribute, the UE shall start the initial registration procedure as described in subclause K.2.1.2.2. In case of a "rejected" event attribute, the UE shall release all dialogs related to those public user identities.

### K.2.1.3 Subscription and notification

The text in subclause 5.1.2 applies without changes.

### K.2.1.4 Generic procedures applicable to all methods excluding the REGISTER method

#### K.2.1.4.1 UE-originating case

The procedures described in subclause 5.1.2A.1 apply with the additional procedures described in the present subclause.

When the UE sends any request, the requirements in subclause 5.1.2A.1 are extended by the following requirements. The UE shall include:

- a Via header field according to the following rules:
  - For UDP, the UE shall include the public IP address or FQDN and the protected server port value in the sent-by field. The UE shall also include the "rport" header field parameter as defined in RFC 3581 [56A]. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT; or
  - For TCP, the UE shall include the public IP address or FQDN of the UE in the sent-by field. The UE shall only use an FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT; and
- if the request contains a Contact header field, include a Contact header field according to the following rules:
  - if this is a request for a new or existing dialog, and the UE did insert a GRUU in the Contact header field, then the UE shall also include its instance ID ("sip.instance" header field parameter), and an "ob" SIP URI parameter as described in RFC 5626 [92]; or
  - if this is a request for a new or existing dialog, and the UE did not insert a GRUU in the Contact header field, then the UE shall include the public IP address of the UE or FQDN and the protected server port value bound to the security association or TLS session in the hostport parameter along with its instance ID ("sip.instance" header field parameter), and an "ob" SIP URI parameter as described in RFC 5626 [92]. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT.

NOTE: The means to ensure that the FQDN resolves to the public IP address of the NAT are outside of the scope of this specification. One option for resolving this is local configuration.

Where a security association or TLS session exists, the UE shall discard any SIP response that is not protected by the security association or TLS session and is received from the P-CSCF outside of the registration and authentication procedures. The requirements on the UE within the registration and authentication procedures are defined in subclause K.2.1.2.

When a SIP transaction times out, i.e. timer B, timer F or timer H expires at the UE, the UE may behave as if timer F expired, as described in subclause K.2.1.2.4.

#### K.2.1.4.2 UE-terminating case

The procedures described in subclause 5.1.2A.2 apply with the additional procedures described in the present subclause.

When the UE sends any response, the requirements in subclause 5.1.2A.2 are extended by the following requirement. If the UE did not include a GRUU in the Contact header field, then the UE shall:

- include the public IP address of the UE or FQDN and the protected server port value bound to the security association or TLS session in the hostport parameter in any Contact header field that is otherwise included. The UE shall only use a FQDN, if it is ensured that the FQDN resolves to the public IP address of the NAT.

The UE shall discard any SIP request that is not integrity protected and is received from the P-CSCF outside of the registration and authentication procedures. The requirements on the UE within the registration and authentication procedures are defined in subclause K.2.1.2.

### K.2.1.5 Maintaining flows and detecting flow failures

STUN Binding Requests are used by the UE as a keep-alive mechanism to maintain NAT bindings for signalling flows over connectionless transport (for dialogs outside a registration as well as within a registration) as well as to determine whether a flow (as described in RFC 5626 [92]) is still valid (e.g. a NAT reboot could cause the transport parameters to change). As such, the UE acts as a STUN client and shall follow the requirements defined by RFC 5389 [100]. Further, when using UDP encapsulated IPsec, the keep-alive capabilities defined within should not be used.

CRLF as defined in RFC 5626 [92] is used by the UE as a keep-alive mechanism to maintain NAT bindings for signalling flows over connection oriented transports (for dialogs outside a registration as well as within a registration) as well as to determine whether a flow (as described in RFC 5626 [92]) is still valid (e.g. a NAT reboot could cause the transport parameters to change). As such, the UE shall follow the requirements defined by RFC 5626 [92].

If the UE determines that the flow to a given P-CSCF is no longer valid (the UE does not receive a STUN reply (or CRLF) or the reply indicates a new public IP Address) the UE shall consider the flow and any associated security associations invalid and perform the initial registration procedures defined in subclause K.2.1.2.2.

When a NAT is not present, it may not be desirable to send keep-alive requests (i.e. given battery considerations for wireless UEs). As such, if a UE can reliably determine that a NAT is not present (i.e. by comparing the "received" header field parameter in the Via header field in the response to the initial un-protected REGISTER request with the locally assigned IP address) then the UE may not perform the keep-alive procedures.

### K.2.1.6 Emergency services

#### K.2.1.6.1 General

In addition to the procedures in subclause 5.1.6.1, the following additional procedures apply. When receiving and sending requests unprotected, the UE shall transmit and receive all SIP messages using the same IP port.

#### K.2.1.6.2 Initial emergency registration

When a UE performs an initial emergency registration the UE shall perform the actions as specified in subclause K.2.1.2.2. The remaining procedures described in subclause 5.1.6.2 apply without modification.

#### K.2.1.6.2A New initial emergency registration

The text in subclause 5.1.6.2A applies without changes.

#### K.2.1.5A.3 Initial subscription to the registration-state event package

The text in subclause 5.1.6.3 applies without changes.

#### K.2.1.6.4 User-initiated emergency reregistration

The UE shall perform user-initiated emergency reregistration as specified in subclause K.2.1.2.4. The remaining procedures described in subclause 5.1.6.4 apply without modification.

#### K.2.1.6.5 Authentication

The UE shall perform the authentication procedures as specified in subclause K.2.1.2.5. The remaining procedures described in subclause 5.1.6.5 apply without modification.

#### K.2.1.6.6 User-initiated emergency deregistration

The text in subclause 5.1.6.6 applies without changes.

### K.2.1.6.7 Network-initiated emergency deregistration

The text in subclause 5.1.6.7 applies without changes.

### K.2.1.6.8 Emergency session setup

#### K.2.1.6.8.1 General

The text in subclause 5.1.6.8.1 applies without changes.

#### K.2.1.6.8.2 Emergency session set-up in case of no registration

The text in subclause 5.1.6.8.2 applies without changes.

#### K.2.1.6.8.3 Emergency session set-up with an emergency registration

After a successful initial emergency registration, the UE shall apply the procedures as specified in subclause K.2.1.4, subclause 5.1.3, and subclause 5.1.4. The remaining procedures described in subclause 5.1.6.8.3 apply without modification.

#### K.2.1.6.8.4 Emergency session set-up within a non-emergency registration

The UE shall apply the procedures as specified in subclause K.2.1.4, subclause 5.1.3, and subclause 5.1.4. The remaining procedures described in subclause 5.1.6.8.4 apply without modification.

### K.2.1.6.9 Emergency session release

The text in subclause 5.1.6.9 applies without changes.

## K.2.2 Procedures at the P-CSCF

### K.2.2.1 Introduction

This subclause describes the SIP procedures for supporting hosted NAT scenarios.

The description enhances the procedures specified in subclause 5.2.

### K.2.2.2 Registration

#### K.2.2.2.1 General

The procedures described in subclause 5.2.2.1 apply without changes.

#### K.2.2.2.2 IMS AKA as a security mechanism

The procedures described in subclause 5.2.2.2 apply with the additional procedures described in the present subclause.

When the P-CSCF receives a REGISTER request from the UE, the P-CSCF shall behave as in subclause 5.2.2.2 with the exception of subitems 2) and 3) which are modified as follows.

2) in case the REGISTER request was received without protection, then:

- a) check the existence of the Security-Client header field. If the Security-Client header field is not present and signalling security is used, then the P-CSCF shall return a suitable 4xx response. If the Security-Client header field is present the P-CSCF shall:
  - in case the UE indicated support for "UDP-enc-tun" then remove and store it; or

- in case the UE does not indicate support for "UDP-enc-tun" then:
  - if the host portion of the sent-by field in the topmost Via header field contains an IP address that differs from the source address of the IP packet, silently drop the REGISTER request;
  - otherwise continue with procedures as of subclause 5.2.2.2;

NOTE 2: If the UE does not indicate support for "UDP-enc-tun" and the P-CSCF detects that the UE is located behind a NAT device, then the P-CSCF can just drop the REGISTER request to avoid unnecessary signalling traffic.

3) in case the REGISTER request was received integrity protected, then the P-CSCF shall:

- a) check the security association which protected the request. If IPsec is used and the security association is a temporary one the P-CSCF shall:
  - in case the hostport parameter in the Contact address is in the form of a FQDN, ensure that the given FQDN will resolve (e.g., by reverse DNS lookup) to the IP address bound to the security association;
  - in case the P-CSCF has detected earlier that the UE is located behind a NAT and IPsec is being used, retrieve port\_Uenc from the encapsulating UDP header of the packet received and complete configuration of the temporary set of security associations by configuring port\_Uenc in each of the temporary security associations;
  - check whether the request contains a Security-Verify header field in addition to a Security-Client header field. If there are no such header fields, then the P-CSCF shall return a suitable 4xx response. If there are such header fields, then the P-CSCF shall compare the content of the Security-Verify header field with the content of the Security-Server header field sent earlier and the content of the Security-Client header field with the content of the Security-Client header field received in the challenged REGISTER request. If those do not match, then there is a potential man-in-the-middle attack. The request should be rejected by sending a suitable 4xx response. If the contents match, the P-CSCF shall remove the Security-Verify and the Security-Client header field;

When the P-CSCF receives a 401 (Unauthorized) response to an unprotected REGISTER request and the P-CSCF previously determined that the UE is behind a NAT and the UE indicated support for "UDP-enc-tun" IPsec mode, the P-CSCF shall:

- 1) delete any temporary set of security associations established towards the UE;
- 2) for IPsec, remove the "ck" and "ik" WWW-Authenticate header field parameters contained in the 401 (Unauthorized) response and bind the values to the proper private user identity and to the temporary set of security associations which will be setup as a result of this challenge. The P-CSCF shall forward the 401 (Unauthorized) response to the UE if and only if the "ck" and "ik" header field parameters have been removed;
- 3) insert a Security-Server header field in the response, containing the P-CSCF security list and the parameters needed. The P-CSCF shall support the setup of two pairs of security associations, as defined in 3GPP TS 33.203 [19]. The syntax of the parameters needed of the IPsec security association setup is specified in annex H of 3GPP TS 33.203 [19]. The P-CSCF shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The P-CSCF shall support the IPsec layer algorithms for integrity protection and for encryption as defined in 3GPP TS 33.203 [19]. The P-CSCF shall indicate "UDP-enc-tun" as the only IPsec mode.
- 4) set up the temporary set of security associations with a temporary SIP level lifetime between the UE and the P-CSCF for the user identified with the private user identity. The P-CSCF shall select UDP encapsulated tunnel mode and shall leave the value for port-Uenc unspecified in each of the temporary security associations. For further details see 3GPP TS 33.203 [19] and RFC 3329 [48]. The P-CSCF shall set the temporary SIP level lifetime for the temporary set of security associations to the value of reg-await-auth timer; and
- 5) send the 401 (Unauthorized) response unprotected to the UE using the mechanisms described in RFC 3261 [26] and RFC 3581 [56A], i.e. the P-CSCF shall send the response to the IP address indicated in the "received" header field parameter and, in case UDP is used, to the port indicated in the "rport" header field parameter (if present) of the Via header field associated with the UE. In case TCP is used as transport protocol, the P-CSCF shall use the port on which the REGISTER request was received as client port for sending the response back to the UE.

When the P-CSCF receives a 401 (Unauthorized) response to a protected REGISTER request and the P-CSCF previously determined that the UE is behind a NAT and that REGISTER request was protected by an old set of security associations that use UDP encapsulated tunnel mode, the P-CSCF shall:

- 1) delete any temporary set of security associations established towards the UE;
- 2) remove the "ck" and "ik" WWW-Authenticate header field parameters contained in the 401 (Unauthorized) response and bind the values to the proper private user identity and to the temporary set of security associations which will be setup as a result of this challenge. The P-CSCF shall forward the 401 (Unauthorized) response to the UE if and only if the "ck" and "ik" header field parameters have been removed;
- 3) insert a Security-Server header field in the response, containing the P-CSCF security list and the parameters needed for the security association setup, as specified in Annex H of 3GPP TS 33.203 [19]. The P-CSCF shall support the "ipsec-3gpp" security mechanism, as specified in RFC 3329 [48]. The P-CSCF shall support the IPsec layer algorithms for integrity protection and encryption as defined in 3GPP TS 33.203 [19]. The P-CSCF shall indicate "UDP-enc-tun" as the IPsec mode;
- 4) set up the temporary set of security associations with a temporary SIP level lifetime between the UE and the P-CSCF for the user identified with the private user identity. The P-CSCF shall select UDP encapsulated tunnel mode and shall specify the same port\_Uenc that was used in the old set of security associations. The P-CSCF shall set the temporary SIP level lifetime for the temporary set of security associations to the value of reg-await-auth timer; and
- 5) send the 401 (Unauthorized) response to the UE using the old set of security associations and using the rules for sending responses as described in RFC 3261 [26] and RFC 3581 [56A], i.e. the P-CSCF shall send the response to the IP address indicated in the "received" header field parameter and if UDP is used, to the port indicated in the "rport" header field parameter (if present) of the Via header field associated with the UE. Otherwise, when the P-CSCF receives a 401 (Unauthorized) response to an unprotected REGISTER request and:
  - this response does not contain a "received" header field parameter in the Via header field associated with the UE;
  - this response does not contain "rport" header field parameter in the Via header field associated with the UE and the request associated with the response was received using UDP; or
  - when the P-CSCF receives a 401 (Unauthorized) response to a protected REGISTER request and that REGISTER request was protected by an old set of security associations that do not use UDP encapsulated tunnel mode;

the P-CSCF shall proceed as described in subclause 5.2.2.2 of the main body of this specification.

#### K.2.2.2.3 SIP digest without TLS as a security mechanism

The text in subclause 5.2.2.3 applies without changes.

#### K.2.2.2.4 SIP digest with TLS as a security mechanism

The procedures described in subclause 5.2.2.4 apply without changes.

#### K.2.2.2.5 NASS-IMS bundled authentication as a security mechanism

The text in subclause 5.2.2.5 applies without changes.

### K.2.2.3 General treatment for all dialogs and standalone transactions excluding the REGISTER method

#### K.2.2.3.1 Requests initiated by the UE

##### K.2.2.3.1.1 General for all requests

The procedures described in subclause 5.2.6.3.1 apply with the additional procedures described in the present subclause.

When the P-CSCF receives from the UE an initial request for a dialog or a request for a standalone transaction, the requirements are extended by the following requirements.

Before forwarding the request, based on the topmost Route header field, in accordance with the procedures of RFC 3261 [26], the P-CSCF shall ensure that all signalling during the lifetime of the dialogue is sent over the same IMS flow set as the dialogue initiating request.

**NOTE:** The suggested way to ensure all signalling is sent over the same IMS flow set is to form an IMS flow token in the same way that a P-CSCF would form this for the Path header field and insert this IMS flow token in the user portion of the URI used in the record route header field value.

#### K.2.2.3.1.2 General for all responses

The procedures in subclause 5.2.6.3.2 apply without changes.

#### K.2.2.3.1.2A Abnormal cases

The text in subclause 5.2.6.3.2A applies without changes.

#### K.2.2.3.1.3 Initial request for a dialog

The text in subclause 5.2.6.3.3 applies without changes.

#### K.2.2.3.1.4 Responses to an initial request for a dialog

The text in subclause 5.2.6.3.4 applies without changes.

#### K.2.2.3.1.5 Target refresh request for a dialog

The text in subclause 5.2.6.3.5 applies without changes.

#### K.2.2.3.1.6 Responses to a target refresh request for a dialog

The text in subclause 5.2.6.3.6 applies without changes.

#### K.2.2.3.1.7 Request for a standalone transaction

The text in subclause 5.2.6.3.7 applies without changes.

#### K.2.2.3.1.8 Responses to a request for a standalone transaction

The text in subclause 5.2.6.3.8 applies without changes.

#### K.2.2.3.1.9 Subsequent request other than a target refresh request

The text in subclause 5.2.6.3.9 applies without changes.

#### K.2.2.3.1.10 Responses to a subsequent request other than a target refresh request

Void

#### K.2.2.3.1.11 Request for an unknown method that does not relate to an existing dialog

The text in subclause 5.2.6.3.11 applies without changes.

#### K.2.2.3.1.12 Responses to a request for an unknown method that does not relate to an existing dialog

Void

### K.2.2.3.2 Requests terminated by the UE

#### K.2.2.3.2.1 General for all requests

Void

#### K.2.2.3.2.2 General for all responses

Void

#### K.2.2.3.2.3 Initial request for a dialog

The procedures described in subclause 5.2.6.4.3 apply with the additional procedures described in the present subclause.

When the P-CSCF receives, destined for the UE, a request, the requirements are extended by the following requirements. The P-CSCF shall:

- forward the request to the terminating UE over the appropriate flow within the denoted IMS flow set.

#### K.2.2.3.2.4 Responses to an initial request for a dialog

The text in subclause 5.2.6.4.4 applies without changes.

#### K.2.2.3.2.5 Target refresh request for a dialog

The procedures described in subclause 5.2.6.4.5 apply with the additional procedures described in the present subclause.

When the P-CSCF receives, destined for the UE, a request, the requirements are extended by the following requirements. The P-CSCF shall:

- forward the request to the terminating UE over the appropriate flow within the denoted IMS flow set.

#### K.2.2.3.2.6 Responses to a target refresh request for a dialog

The text in subclause 5.2.6.4.6 applies without changes.

#### K.2.2.3.2.7 Request for a standalone transaction

The procedures described in subclause 5.2.6.4.7 apply with the additional procedures described in the present subclause.

When the P-CSCF receives, destined for the UE, a request, the requirements are extended by the following requirements. The P-CSCF shall:

- forward the request to the terminating UE over the appropriate flow within the denoted IMS flow set.

#### K.2.2.3.2.8 Responses to a request for a standalone transaction

The text in subclause 5.2.6.4.8 applies without changes.

#### K.2.2.3.2.9 Subsequent request other than a target refresh request

The procedures described in subclause 5.2.6.4.9 apply with the additional procedures described in the present subclause.

When the P-CSCF receives, destined for the UE, a request, the requirements are extended by the following requirements. The P-CSCF shall:

- forward the request to the terminating UE over the appropriate flow within the denoted IMS flow set.

#### K.2.2.3.2.10 Responses to a subsequent request other than a target refresh request

The text in subclause 5.2.6.4.10 applies without changes.

K.2.2.3.2.11 Request for an unknown method that does not relate to an existing dialog

Void

K.2.2.3.2.12 Responses to a request for an unknown method that does not relate to an existing dialog

Void

K.2.2.4 Void

K.2.2.5 Emergency services

K.2.2.5.1 General

The procedures described in subclause 5.2.10.1 apply without changes.

K.2.2.5.2 General treatment for all dialogs and standalone transactions excluding the REGISTER method – from an unregistered user

The procedures described in subclause 5.2.10.2 apply with the additional procedures described in the present subclause.

When the P-CSCF receives from the UE an initial request for a dialog or a request for a standalone transaction, the requirements are extended by the following requirements.

Before forwarding the request, based on the topmost Route header field, in accordance with the procedures of RFC 3261 [26], the P-CSCF shall ensure that all signalling during the lifetime of the dialogue is sent over the same IMS flow set as the dialogue initiating request.

NOTE: The suggested way to ensure all signalling is sent over the same IMS flow set is to form an IMS flow token in the same way that a P-CSCF would form this for the Path header field and insert this IMS flow token in the user portion of the URI used in the Record-Route header field value.

K.2.2.5.3 General treatment for all dialogs and standalone transactions excluding the REGISTER method after emergency registration

The procedures described in subclause 5.2.10.3 apply with the additional procedures described in the present subclause.

When the P-CSCF receives from the UE an initial request for a dialog, or a standalone transaction, or an unknown method, the following requirements:

- 1) include in the Request-URI an emergency service URN, i.e. a service URN with a top-level service type of "sos" as specified in RFC 5031 [69], if necessary, and execute the procedure described in step 4, 5, 6, and 7, in subclause 5.2.6.3.3, subclause 5.2.6.3.7, subclause 5.2.6.3.11, subclause 5.2.7.2 and subclause K.2.2.3.1, as appropriate. An additional sub-service type can be added if information on the type of emergency service is known. The entry in the Request-URI that the P-CSCF includes may either be:
  - as received from the UE in the Request-URI in accordance with RFC 5031 [69]; or
  - as deduced from the Request-URI received from the UE.

K.2.2.5.4 General treatment for all dialogs and standalone transactions excluding the REGISTER method – non-emergency registration

The procedures described in subclause 5.2.10.4 apply with the additional procedures described in the present subclause.

When the P-CSCF receives from the UE an initial request for a dialog, or a standalone transaction, or an unknown method, the following requirements are extended:

1) include in the Request-URI an emergency service URN, i.e. a service URN with a top-level service type of "sos" as specified in RFC 5031 [69], if necessary, and execute the procedure described in step 3, 4, 5, 6, and 7, in subclause 5.2.6.3.3, subclause 5.2.6.3.7, subclause 5.2.6.3.11 subclause 5.2.7.2 and subclause K.2.2.3.1, as appropriate. An additional sub-service type can be added if information on the type of emergency service is known. The entry in the Request-URI that the P-CSCF includes may either be:

- as received from the UE in the Request-URI in accordance with RFC 5031 [69]; or
- as deduced from the Request-URI received from the UE; and

#### K.2.2.5.5 Abnormal cases

The text in subclause 5.2.10.5 applies without changes.

### K.2.4 Void

---

## K.3 Application usage of SDP

### K.3.1 UE usage of SDP

The procedures as of subclause 6.1 apply.

### K.3.2 P-CSCF usage of SDP

The procedures as of subclause 6.2 apply.

---

## K.4 Void

## K.5 Application usage of ICE

### K.5.1 Introduction

The following subclauses describe the usage of the Interactive Connectivity Establishment (ICE) procedures as documented in RFC 5245 [99]

### K.5.2 UE usage of ICE

#### K.5.2.1 General

NAT bindings also need to be kept alive for media. RFC 5245 [99] provides requirements for STUN based keepalive mechanisms. UEs that do not implement the ICE procedures as defined in RFC 5245 [99] should implement the keepalive procedures defined in RFC 5245 [99]. In the case where keepalives are required and the other end does not support ICE (such that STUN cannot be used for a keepalive) or the UE can not discover STUN or TURN servers to gather candidates, the UE shall send an empty (no payload) RTP packet with a payload type of 20 as a keepalive as long as the other end has not negotiated the use of this value. If this value has already been negotiated, then some other unused static payload type from table 5 of RFC 3551 [55A] shall be used. When sending an empty RTP packet, the UE shall continue using the sequence number (SSRC) and timestamp as the negotiated RTP stream.

### K.5.2.2 Call initiation – UE-origination case

The UE should support the agent requirements for ICE as defined by RFC 5245 [99] when sending the initial INVITE request. RFC 5245 [99] provides procedures for:

- 1) Gathering candidate addresses for RTP and RTCP prior to sending the INVITE;
- 2) Encoding the candidate addresses in the SDP that is included with the INVITE;
- 3) Acting as a STUN server to receive binding requests from the remote client when it does connectivity checks;
- 4) Performing connectivity checks on received candidate addresses for RTP and RTCP;
- 5) Determining and possibly selecting a better active address based on the requirements in RFC 5245 [99];
- 6) Subsequent offer/answer exchanges; and
- 7) Sending media.

When supporting the ICE procedures, the UE shall also support the STUN agent requirements as described in RFC 5389 [100] in order to gather STUN addresses, the TURN client requirements as described in RFC 5766 [101] in order to gather TURN Server addresses and the STUN Server requirements defined in RFC 5245 [99] as well as the requirements for STUN Servers defined in RFC 5389 [100] for responding to connectivity checks.

RFC 5245 [99] provides an algorithm for determining the priority of a particular candidate. The following additional requirements are provided to the UE:

- 1) The type preference assigned for each type of candidate from least to highest should be: Relayed Transport Address, STUN address, local address; and
- 2) If the UE has a dual IPv4/IPv6 stack, IPv6 addresses may be assigned a higher local preference than IPv4 addresses based on the operator's policy.

RFC 5245 [99] provides guidance on choosing the in-use candidate and recommends that a UE choose relayed candidates as the in-use address. The following additional requirements are provided to the UE:

- 1) If a TURN server is available, the Relayed Transport Address should be used as the initial active transport address (i.e. as advertised in the m/c lines of the SDP); and
- 2) If a TURN server is not available, an address obtained via STUN should be used as the initial active transport address.

Regardless of whether the UE supports the above procedures, the UE shall, upon receipt of an SDP answer with candidate addresses, perform connectivity checks on the candidate addresses as described in RFC 5245 [99]. In order to perform connectivity checks, the UE shall act as a STUN client as defined in RFC 5389 [100]. Further, the UE shall also follow the procedures in RFC 5245 [99] when sending media.

### K.5.2.3 Call termination – UE-termination case

The UE should support agent requirements for ICE as defined by RFC 5245 [99] when receiving an initial INVITE request. RFC 5245 [99] provides procedures for:

- 1) Gathering candidate addresses for RTP and RTCP prior to sending the answer as described in RFC 5245 [99];
- 2) Encoding the candidate addresses in the SDP answer as described in RFC 5245 [99];
- 3) Acting as a STUN server to receive binding requests from the remote client when it does connectivity checks;
- 4) Performing connectivity checks on received candidate addresses for RTP and RTCP;
- 5) Determining and possibly selecting a better active address based on the requirements in RFC 5245 [99];
- 6) Subsequent offer/answer exchanges; and
- 7) Sending media.

When supporting the ICE procedures, the UE shall also support the STUN agent requirements as described in RFC 5389 [100] in order to gather STUN addresses, the TURN client requirements as described in RFC 5766 [101] in order to gather TURN Server addresses and the STUN Server requirements defined in RFC 5245 [99] as well as the requirements for STUN Servers defined in RFC 5389 [100] for responding to connectivity checks.

RFC 5245 [99] provides an algorithm for determining the priority of a given candidate. The additional requirements for the UE:

- 1) The priority of candidate addresses from least to highest should be: Relayed Transport Address, STUN address, local address; and
- 2) If the UE has a dual IPv4/IPv6 stack, IPv6 addresses MAY be placed at a higher priority than IPV4 addresses based on the operator's policy.

RFC 5245 [99] provides guidance on choosing the in-use candidate and recommends that a UE choose relayed candidates as the in-use address. The following additional requirements are provided to the UE:

- 1) If a TURN server is available, the Relayed Transport Address should be used as the initial active transport address (i.e. as advertised in the m/c lines of the SDP); and
- 2) If a TURN server is not available, an address obtained via STUN should be used as the initial active transport address.

Regardless of whether the UE supports the above procedures, the UE shall, upon receipt of an SDP offer with candidate addresses, perform connectivity checks on the candidate addresses as described in RFC 5245 [99]. In order to perform connectivity checks, the UE shall act as a STUN client as defined in RFC 5389 [100]. Further, the UE shall also follow the procedures in RFC 5245 [99] when sending media.

When receiving an SDP offer which does not indicate support for ICE, the UE aborts the ICE procedures and reverts to RFC 3264 [27B] offer/answer procedures; per RFC 5245 [99]. However, if the terminating UE is behind a NA(P)T device this may result in the inability to pass media for the session as the terminating UE will respond with its locally assigned IP address which is unreachable. In order to ensure successful media exchange, the terminating UE shall provide either a STUN derived IP address and port or a TURN provided IP address and port in the m/c lines of the SDP answer. If the provided address and port is a TURN address and port, the policy charging and control framework will be unable to establish proper filter criteria as the address is that of the TURN server and not that of the UE or NAT in front of the UE; see RFC 5245 [99] subclause B.3 for further details. To rectify this issue, the terminating UE shall also include a candidate attribute as described in RFC 5245 [99] identifying the server reflexive IP address and port (i.e. the IP address and port on the public side of the NAT) used when a TURN provided address and port is provided in the m/c line of the SDP answer.

### K.5.3 P-CSCF support of ICE

The P-CSCF procedures to support ICE as specified in RFC 5245 [99] are defined in subclause 6.7.2.7.

### K.5.4 Void

---

# Annex L (normative): IP-Connectivity Access Network specific concepts when using EPS to access IM CN subsystem

## L.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is Evolved Packet System (EPS). The EPS IP-CAN has an EPS core network which can be supported by an E-UTRAN radio access network.

---

## L.2 EPS aspects when connected to the IM CN subsystem via E-UTRAN

### L.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by EPS to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause. Requirements for the P-GW in support of this communication are specified in 3GPP TS 29.061 [11], and 3GPP TS 29.212 [13B].

When using the EPS, each IP-CAN bearer is provided by an EPS bearer.

### L.2.2 Procedures at the UE

#### L.2.2.1 EPS bearer context activation and P-CSCF discovery

The policy on the PDN connection established during the EPS attach procedure identifies parameters for composing the ESM messages sent during the EPS attach procedure as specified in 3GPP TS 24.301 [8J], when the UE performs the EPS attach procedure in order to communicate with IM CN subsystem.

The UE may support the policy on the PDN connection established during the EPS attach procedure.

If the UE supports the policy on the PDN connection established during the EPS attach procedure, the UE may support being configured with the policy on the PDN connection established during the EPS attach procedure using one or more of the following methods:

- a) the EPS\_initial\_attach\_ConRefs node of EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the EPS\_initial\_attach\_ConRefs node of EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the EPS\_initial\_attach\_ConRefs node of 3GPP TS 24.167 [8G].

If the UE is configured with both the EPS\_initial\_attach\_ConRefs node of 3GPP TS 24.167 [8G] and the EPS\_initial\_attach\_ConRefs node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the EPS\_initial\_attach\_ConRefs node of the EF<sub>IMSConfigData</sub> file shall take precedence.

NOTE 1: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

Prior to communication with the IM CN subsystem, the UE shall:

- a) if not attached for EPS services yet, perform a EPS attach procedure as specified in 3GPP TS 24.301 [8J]. If the UE requests establishment of a PDN connection during the EPS attach procedure, and the UE supports and is

configured with the policy on the PDN connection established during the EPS attach procedure, the UE shall compose the ESM messages sent during the EPS attach procedure, according to the policy on the PDN connection established during the EPS attach procedure;

- b) ensure that a EPS bearer context used for SIP signalling according to the APN and P-GW selection criteria described in 3GPP TS 23.401 [7B], is available. This EPS bearer context shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration. As a result, the EPS bearer context provides the UE with information that makes the UE able to construct an IPv4 or an IPv6 address;

NOTE 2: The default EPS bearer context can also be used for SIP signalling as well as any other EPS bearer context.

When the EPS bearer context establishment procedure for the SIP signalling is initiated by the UE:

- I. if a default EPS bearer context is not available with the selected P-GW, the UE shall indicate to the network in the PDN CONNECTIVITY REQUEST that the request is for SIP signalling. If the request is authorized, the network establishes a bearer with the appropriate QCI as described in 3GPP TS 24.301 [8J]. The UE may also use this EPS bearer context for DNS and DHCP signalling;
- II. if the default EPS bearer context is available with the selected P-GW, and is to be used for SIP signalling no additional steps are needed; and
- III. if the default EPS bearer context is available with the selected P-GW and an EPS bearer for SIP signalling with the correct QCI and TFT is to be established, the UE shall indicate to the network, by setting the IM CN Subsystem Signalling Flag in the Protocol Configuration Options information element in the BEARER RESOURCE ALLOCATION REQUEST message, that the request is for SIP signalling. If the request is authorized, the network either establishes a new dedicated bearer or modifies an existing bearer with the appropriate QCI and TFT as described in 3GPP TS 24.301 [8J]. The general QoS negotiation mechanism is described in 3GPP TS 24.301 [8J]; and

NOTE 3: An EPS bearer with a QCI value other than the one for signalling can carry both IM CN subsystem signalling and media, in case the media does not need to be authorized by Policy and Charging control mechanisms as defined in 3GPP TS 29.212 [13B] and the media stream is not mandated by the P-CSCF to be carried in a separate EPS bearer.

- c) acquire a P-CSCF address(es).

The methods for P-CSCF discovery are:

- I. When using IPv4, employ the Dynamic Host Configuration Protocol (DHCP) RFC 2132 [20F], the DHCPv4 options for SIP servers RFC 3361 [35A], and RFC 3263 [27A] as described in subclause 9.2.1. When using IPv6, employ Dynamic Host Configuration Protocol for IPv6 (DHCPv6) RFC 3315 [40], the DHCPv6 options for SIP servers RFC 3319 [41] and DHCPv6 options for Domain Name Servers (DNS) RFC 3646 [56C] as described in subclause 9.2.1.
- II. Transfer P-CSCF address(es) within the EPS bearer context activation procedure.

The UE shall indicate the request for a P-CSCF address to the network within the Protocol Configuration Options information element of the PDN CONNECTIVITY REQUEST message or BEARER RESOURCE ALLOCATION REQUEST message.

If the network provides the UE with a list of P-CSCF IPv4 or IPv6 addresses in the ACTIVATE DEFAULT EPS BEARER CONTEXT REQUEST message or ACTIVATE DEDICATED EPS BEARER CONTEXT REQUEST message, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the highest preference and the last P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the lowest preference.

- III. The UE selects a P-CSCF from the list (see 3GPP TS 31.103 [15B]) stored in the ISIM.

- IV. The UE selects a P-CSCF from the list in IMS management object.

The UE shall use method IV to select a P-CSCF, if

- a P-CSCF is to be discovered in the home network;
- the UE is roaming; and
- the IMS management object contains the P-CSCF list.

The UE shall use method III to select the P-CSCF, if:

- a P-CSCF is to be discovered in the home network;
- the UE is roaming;
- either the UE does not contain the IMS management object, or the UE contains the IMS management object but the IMS management object does not contain the P-CSCF list; and
- the ISIM residing in the UICC supports the P-CSCF list.

The UE can freely select method I or II for P-CSCF discovery, if:

- the UE is in the home network; or
- the UE is roaming and the P-CSCF is to be discovered in the visited network.

The UE can select method IV, if:

- the UE is in the home network; and
- the IMS management object contains the P-CSCF list.

In case method I is selected and several P-CSCF addresses or FQDNs are provided to the UE, the selection of P-CSCF address or FQDN shall be performed as indicated in RFC 3361 [35A] when using IPv4 or RFC 3319 [41] when using IPv6. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the UE is implementation specific.

NOTE 4: The UE decides whether the P-CSCF is to be discovered in the serving network or in the home network based on local configuration, e.g. whether the application on the UE is permitted to use local breakout.

If the UE is designed to use I above, but receives P-CSCF address(es) according to II, then the UE shall either ignore the received address(es), or use the address(es) in accordance with II, and not proceed with the DHCP request according to I.

If the UE is configured to use Option II above and detects that all P-CSCFs known by the UE have been used when the UE selects a different P-CSCF as a result of:

- receiving 305 (Use Proxy) to the REGISTER request;
- receiving 504 (Server Time-out); or
- expiration of the timer F at the UE,

then if there are more than one PDN connection that UE is connected to and unless the IP-CAN bearer is in use by other applications, the UE shall:

- 1) release IP-CAN bearer that is used only for the transport of SIP signalling and that are not used for other non-IMS applications, but shall not release emergency IP-CAN bearers; and
- 2) unless the UE decides the service is no longer needed,
  - a) perform a new P-CSCF discovery procedure as described in subclause 9.2.1; and
  - b) perform the procedures for initial registration as described in subclause 5.1.1.2.

When using IPv4, the UE may request a DNS Server IPv4 address(es) via RFC 2132 [20F] or by the Protocol Configuration Options information element when activating a EPS bearer context according to 3GPP TS 24.301 [8J].

When using IPv6, the UE may request a DNS Server IPv6 address(es) via RFC 3315 [40] and RFC 3646 [56C] or by the Protocol Configuration Options information element when activating an EPS bearer context according to 3GPP TS 24.301 [8J].

The encoding of the request and response for IPv4 or IPv6 address(es) for DNS server(s) and list of P-CSCF address(es) within the Protocol Configuration Options information element is described in 3GPP TS 24.301 [8J].

When:

- the UE obtains an EPS bearer context used for SIP signalling by performing handover of the connection from another IP-CAN;
- IP address of the UE is not changed during the handover; and
- the UE already communicates with the IM CN subsystem via the connection with the other IP-CAN, e.g. the UE determines that its contact with host portion set to the UE IP address (or FQDN of the UE) associated with the connection with the other IP-CAN has been bound to a public user identity;

the UE shall continue using the P-CSCF address(es) acquired in the other IP-CAN.

The UE may support the policy on when a UE roaming in a VPLMN is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS. If the UE roams in the EPS IP-CAN, has a session and the policy indicates "roaming in a VPLMN and having an ongoing session, is not allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS", the UE shall not handover the PDN connection providing access to IMS from EPC via WLAN to EPS.

If the UE roams in the EPS IP-CAN, has a session and the policy indicates "roaming in a VPLMN and having an ongoing session, is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS", the UE shall, if not prevented by other rules or policies, handover the PDN connection providing access to IMS from EPC via WLAN to EPS.

If the UE roams in the EPS IP-CAN and the policy indicates "roaming in a VPLMN is not allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS, irrespective of if the UE is in a session or not", the UE shall not handover the PDN connection providing access to IMS from EPC via WLAN to EPS. The UE can re-establish a new PDN connection to another IP-CAN type in idle mode, e.g. due to UE domain preference.

If the UE supports the policy on whether a roaming UE when in a session is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS, the UE may support being configured with the policy on whether a roaming UE when in a session is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN EPS using one or more of the following methods:

- a) the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of 3GPP TS 24.167 [8G].

If the UE is configured with both the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of 3GPP TS 24.167 [8G] and the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the Allow\_Handover\_PDN\_connection\_WLAN\_And\_EPS node of the EF<sub>IMSConfigData</sub> file shall take precedence.

NOTE 5: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

## L.2.2.1A Modification of a EPS bearer context used for SIP signalling

The EPS bearer context shall not be modified from being used exclusively for SIP signalling to a general purpose EPS bearer. After the establishment of an EPS bearer context used for SIP signalling, the UE shall not set the IM CN Subsystem Signalling Flag in the Protocol Configuration Options information element of any subsequent BEARER RESOURCE MODIFICATION REQUEST message for that APN. The UE shall ignore the IM CN Subsystem Signalling Flag if received from the network in the Protocol Configuration Options information element.

After the establishment of a EPS bearer context used for SIP signalling, the UE shall not indicate the request for a P-CSCF address to the network within the Protocol Configuration Options information element of any subsequent BEARER RESOURCE MODIFICATION REQUEST message for that APN. The UE shall ignore P-CSCF address(es) if received from the network in the Protocol Configuration Options information element.

### L.2.2.1B Re-establishment of the EPS bearer context for SIP signalling

If the UE registered a public user identity with an IP address allocated for the APN of the EPS bearer context used for SIP signalling, the EPS bearer context used for SIP signalling is deactivated as result of signalling from the network and:

- i) if the UE is required to perform an initial registration according to subclause L.3.1.2;
- ii) if the signalling from the network results in requiring the UE to initiate activation of the PDN connection of the EPS bearer context used for SIP signalling; or
- iii) if the UE needs to continue having a public user identity registered with an IP address allocated for the APN;

the UE shall:

- A) if the non-access stratum is performing the UE requested PDN connectivity procedure and the EPS bearer context activation procedure(s) for the APN triggered as result of the signalling from the network, wait until the UE requested PDN connectivity procedure and the EPS bearer context activation procedure(s) for the APN finish; and
- B) perform the procedures in subclause L.2.2.1, bullets a), b) and c).

If none of the bullets i), ii) and iii) of this subclause evaluate to true, or the procedures in bullet B) of this subclause were unable to ensure that the EPS bearer context used for SIP signalling is available or were unable to acquire any P-CSCF address(es):

- 1) if the SIP signalling was carried over a dedicated EPS bearer context, the UE shall release all resources established as a result of SIP signalling by sending to the network either:
  - a) a BEARER RESOURCE MODIFICATION REQUEST message, if there are EPS bearer contexts to this PDN that are not related SIP sessions; or
  - b) a PDN DISCONNECT REQUEST message if all the EPS bearer contexts to this PDN are related to SIP sessions.

NOTE: If the SIP signalling was carried over the default EPS bearer context, all the resources established as a result of SIP signalling are released without any explicit NAS signalling.

If the default EPS bearer context of the PDN connection of the EPS bearer context used for SIP signalling was deactivated at the start of this subclause, and the procedures in bullet B) of this subclause ensured that the EPS bearer context used for SIP signalling is available and acquired the P-CSCF address(es), the UE shall perform a new initial registration according to subclause 5.1.1.2.

### L.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure performs one of the following procedures:

- A) if the UE used method II for P-CSCF discovery and if the UE receives one or more P-CSCF address(es) in the Protocol Configuration Options information element of a Modify EPS Bearer Context Request message the one or more P-CSCF address(es) do not include the address of the currently used P-CSCF, then the UE shall acquire a different P-CSCF address from the one or more P-CSCF address(es) in the Modify EPS Bearer Context Request message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority.

If the UE used method II for P-CSCF discovery and if the UE has previously sent the "P-CSCF Re-selection support" PCO indicator at PDN creation and if the UE receives one or more P-CSCF address(es) in the Protocol

Configuration Options information element of a Modify EPS Bearer Context Request message, then the UE shall acquire a P-CSCF address from the one or more P-CSCF addresse(s) in the Modify EPS Bearer Context Request message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority;

- B if the UE uses RFC 6223 [143] as part of P-CSCF restoration procedures, and if the P-CSCF fails to respond to a keep-alive request, then the UE shall acquire a different P-CSCF address using one of the methods I, III and IV for P-CSCF discovery described in the subclause L.2.2.1.

If the UE has an ongoing session and acquired the new P-CSCF address by using procedure A described above, the UE may wait until the UE has detected that the ongoing session has ended before performing an initial registration as specified in subclause 5.1.

In all other cases, when the UE has acquired the P-CSCF address, the UE not having an ongoing session shall perform an initial registration as specified in subclause 5.1.

NOTE 1: For UEs using procedure A described above, the network ensures that P-CSCF address(es) in the Protocol Configuration Options information element of a Modify EPS Bearer Context Request message is sent only during P-CSCF restoration procedures as defined in subclause 5 of 3GPP TS 23.380 [7D].

NOTE 2: The P-CSCF can be completely unreachable, so it is up to UE implementation to detect the end of an ongoing session, e.g. using media plane inactivity detection. Services depending on signalling such as CW and MT calls will not work during this time.

## L.2.2.2 Session management procedures

The existing procedures for session management as described in 3GPP TS 24.301 [8J] shall apply while the UE is connected to the IM CN subsystem.

## L.2.2.3 Mobility management procedures

The existing procedures for mobility management as described in 3GPP TS 24.301 [8J] shall apply while the UE is connected to the IM CN subsystem.

## L.2.2.4 Cell selection and lack of coverage

The existing mechanisms and criteria for cell selection as described in 3GPP TS 36.304 [19B] shall apply while the UE is connected to the IM CN subsystem.

## L.2.2.5 EPS bearer contexts for media

### L.2.2.5.1 General requirements

NOTE 1: In EPS, the UE cannot control whether media streams belonging to different SIP sessions are established on the same EPS bearer context or not. During establishment of a session, the UE establishes data streams(s) for media related to the session. Such data stream(s) can result in activation of additional EPS bearer context(s). Either the UE or the network can request for resource allocations for media, but the establishment and modification of the EPS bearer is controlled by the network as described in 3GPP TS 24.301 [8J].

NOTE 2: When the UE wishes to allocate bandwidth for RTP and RTCP, the UE uses the rules as those outlined in 3GPP TS 29.213 [13C].

If the resource allocation is initiated by the UE, the UE starts reserving resources whenever it has sufficient information about the media streams, and used codecs available as specified in 3GPP TS 24.301 [8J].

NOTE 3: If the resource reservation requests are initiated by the EPS IP CAN, then the bearer establishment is initiated by the network after the P-CSCF has authorised the respective IP flows and provided the QoS requirements over the Rx interface to the PCRF as described in 3GPP TS 29.214 [13D].

#### L.2.2.5.1A Activation or modification of EPS bearer contexts for media by the UE

If the UE is configured not to initiate resource allocation for media according to 3GPP TS 24.167 [8G], then the UE shall refrain from requesting additional EPS bearer context(s) for media until the UE considers that the network did not initiate resource allocation for the media.

#### L.2.2.5.1B Activation or modification of EPS bearer contexts for media by the network

If the UE receives an activation request from the network for a EPS bearer context which is associated with the EPS bearer context used for signalling, the UE shall, based on the information contained in the Traffic Flow Template information element, correlate the media EPS bearer context with a currently ongoing SIP session establishment or SIP session modification.

If the UE receives a modification request from the network for a EPS bearer context that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) modify the related EPS bearer context in accordance with the request received from the network.

#### L.2.2.5.1C Deactivation of EPS bearer context for media

When a data stream for media related to a session is released, if the EPS bearer resource transporting the data stream is no longer needed and allocation of the EPS bearer resource was requested by the UE, then the UE releases the EPS bearer resource.

NOTE: The EPS bearer resource can be needed e.g. for other data streams of a session or for other applications in the UE.

#### L.2.2.5.1D Default EPS bearer context usage restriction policy

The default EPS bearer context usage restriction policy consists of zero or more default EPS bearer context usage restriction policy parts.

The default EPS bearer context usage restriction policy part consists of a mandatory media type condition and an optional ICSI condition.

The default EPS bearer context usage restriction policy does not apply to UE detected emergency calls.

Sending media is restricted according to the default EPS bearer context usage restriction policy, if sending media is restricted according to at least one default EPS bearer context usage restriction policy part of the default EPS bearer context usage restriction policy.

Sending media is restricted according to the default EPS bearer context usage restriction policy part if:

- 1) the media is to be sent for a media stream negotiated in a session offered or established by SIP signalling;
- 2) the media stream is of a media type indicated in the media type condition of the EPS bearer context usage restriction policy part;
- 3) the following is true:
  - a) the default EPS bearer context usage restriction policy part does not have the ICSI condition; or
  - b) the session is offered or established by SIP signalling related to an IMS communication service identified in the ICSI condition of the default EPS bearer context usage restriction policy part; and
- 4) the media is to be sent via the default EPS bearer context of the PDN connection for SIP signalling.

The UE may support the default EPS bearer context usage restriction policy.

If the UE supports the default EPS bearer context usage restriction policy:

- 1) the UE shall not send media restricted according to the default EPS bearer context usage restriction policy; and

- 2) the UE may support being configured with the default EPS bearer context usage restriction policy using one or more of the following methods:
  - a) the Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of the EF<sub>IMSCConfigData</sub> file described in 3GPP TS 31.102 [15C];
  - b) the Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of the EF<sub>IMSCConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
  - c) Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of 3GPP TS 24.167 [8G].

If the UE is configured with both the the Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of 3GPP TS 24.167 [8G] and the Ethe Default\_EPS\_bearer\_context\_usage\_restriction\_policy node of F<sub>IMSCConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the EF<sub>IMSCConfigData</sub> file shall take precedence.

NOTE: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

### L.2.2.5.2 Special requirements applying to forked responses

NOTE 1: The procedures in this subclause only apply when the UE requests activation and modification of media bearers. In the case where the network activates and modifies the media bearers the network takes care of the handling of media bearers in the case of forking.

Since the UE does not know that forking has occurred until a second, provisional response arrives, the UE requests resource allocation as required by the initial response received. If a subsequent provisional response is received, different alternative actions may be performed depending on the requirements in the SDP answer:

- 1) the bearer requirements of the subsequent SDP can be accommodated by the existing resources requested. The UE performs no further resource requests.
- 2) the subsequent SDP introduces different QoS requirements or additional IP flows. The UE requests further resource allocation according to subclause L.2.2.5.1.
- 3) the subsequent SDP introduces one or more additional IP flows. The UE requests further resource allocation according to subclause L.2.2.5.1.

NOTE 2: When several forked responses are received, the resources requested by the UE are the "logical OR" of the resources indicated in the multiple responses to avoid allocation of unnecessary resources. The UE does not request more resources than proposed in the original INVITE request.

When a final answer is received for one of the early dialogs, the UE proceeds to set up the SIP session. The UE shall release all the unneeded IP-CAN resources. Therefore, upon the reception of the first final 200 (OK) response for the INVITE request (in addition to the procedures defined in RFC 3261 [26] subclause 13.2.2.4), the UE shall:

- 1) in case resources were established or modified as a consequence of the INVITE request and forked provisional responses that are not related to the accepted 200 (OK) response, send release request to release the unneeded resources.

### L.2.2.5.3 Unsuccessful situations

One of the Rx and Gx interface related error codes can be received by the UE in either the PDN CONNECTIVITY REJECT message, the BEARER RESOURCE MODIFICATION REJECT message, or the BEARER RESOURCE ALLOCATION REJECT message. If the UE receives a Rx and Gx interface related error code, the UE shall either handle the resource reservation failure as described in subclause 6.1.1 or retransmit the message up to three times. The Rx and Gx interface related error codes are further specified in 3GPP TS 29.214 [13D] and 3GPP TS 29.212 [13B].

## L.2.2.6 Emergency service

### L.2.2.6.1 General

Emergency bearers are defined for use in emergency calls in EPS and core network support of these bearers is indicated to the UE in NAS signalling. Where the UE recognises that a call request is an emergency call and the core network

supports emergency bearers, the UE shall use these EPS bearer contexts for both signalling and media for emergency calls made using the IM CN subsystem.

Some jurisdictions allow emergency calls to be made when the UE does not contain an ISIM or USIM, or where the credentials are not accepted. Additionally, where the UE is in state EMM-REGISTERED.LIMITED-SERVICE and EMM-REGISTERED.PLMN-SEARCH, a normal ATTACH has been attempted but it can also be assumed that a registration in the IM CN subsystem will also fail. In such cases, subject to the lower layers indicating that the network does support emergency bearer services in limited service state (see 3GPP TS 36.331 [19F]), the procedures for emergency calls without registration can be applied, as defined in subclause 5.1.6.8.2. If the EPS authentication procedure has already succeeded during the latest normal or emergency ATTACH procedure, the UE shall perform an initial emergency registration, as described in subclause 5.1.6.2 before attempting an emergency call as described in subclause 5.1.6.8.3.

NOTE 1: The UE can determine that EPS authentication procedure has succeeded during the emergency ATTACH procedure when a non-null integrity protection algorithm (i.e. other than EIA0 algorithm) is received in the NAS signalling SECURITY MODE COMMAND message.

When activating an EPS bearer context to perform emergency registration, the UE shall request a PDN connection for emergency bearer services as described in 3GPP TS 24.301 [8J]. The procedures for EPS bearer context activation and P-CSCF discovery, as described in subclause L.2.2.1 of this specification apply accordingly.

In order to find out whether the UE is attached to the home PLMN or to the visited PLMN, the UE shall compare the MCC and MNC values derived from its IMSI with the MCC and MNC of the PLMN the UE is attached to. If the MCC and MNC of the PLMN the UE is attached to do not match with the MCC and MNC derived from the IMSI, then for the purpose of emergency calls in the IM CN subsystem the UE shall consider to be attached to a VPLMN.

NOTE 2: In this respect an equivalent HPLMN, as defined in 3GPP TS 23.122 [4C] will be considered as a visited network.

NOTE 3: The UE verifies if a detected emergency number is still present in the Extended Local Emergency Number List after attach to a different PLMN. It is possible for the number to no longer be present in the Extended Local Emergency Number List if:

- the PLMN attached to relies on the Local Emergency Number List for deriving a URN; or
- the previously received Extended Emergency Number List Validity field indicated "Extended Local Emergency Numbers List is valid only in the PLMN from which this IE is received".

If the UE detected an emergency number, the UE subsequently performs an attach procedure or an emergency attach procedure with a different PLMN than the PLMN from which the UE received the last Extended Local Emergency Number List, the dialled number is not stored in the ME, in the USIM and in the Local Emergency Number List; and

- the ATTACH ACCEPT message received from the different PLMN contains the Extended Local Emergency Number List and the emergency number is present in the updated Extended Local Emergency Number List then the UE uses the updated Extended Local Emergency Number List when it performs the procedures in subclause L.2.2.6.1B; and
- the ATTACH ACCEPT message received from the different PLMN contains no Extended Local Emergency Number List or the emergency number is no longer present in the updated Extended Local Emergency Number List then the UE shall attempt UE procedures for SIP that relate to emergency using emergency service URN "urn:service:sos".

If the dialled number is equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]), then the UE shall recognize such a number as for an emergency call and:

- if the dialled number is equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform either procedures in the subclause L.2.2.6.1B or the procedures in subclause L.2.2.6.1A; and
- if the dialled number is not equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform procedures in the subclause L.2.2.6.1B.

If the dialled number is not equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]) and:

- if the dialled number is equal to an emergency number stored in the ME, in the USIM or in the Local Emergency Number List (as defined in 3GPP TS 24.008 [8]), then the UE shall recognize such a number as for an emergency call and performs the procedures in subclause L.2.2.6.1A.

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, if:

- the 380 (Alternate Service) response contains a Contact header field;
- the value of the Contact header field is a service URN; and
- the service URN has a top-level service type of "sos";

then the UE determines that "emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.3.1 if the 380 (Alternate Service) response does not contain a Contact header field with service URN that has a top-level service type of "sos", then the UE determines that "no emergency service information is included" as described 3GPP TS 23.167 [4B].

If the "emergency service information is included" as described 3GPP TS 23.167 [4B]:

- 1) if the URN in the Contact header field matches an emergency service URN in table L.2.2.6.1, then the type of emergency service is the value corresponding to the matching entry in table L.2.2.6.1; and
- 2) if the URN in the Contact header field does not match any emergency service URN in table L.2.2.6.1, then the type of emergency service is not identified.

NOTE 4: In bullet 2), the URN in the Contact header field either contains "no emergency subservice type" as described in 3GPP TS 23.167 [4B] triggering an emergency call, or contains an "emergency subservice type that does not map into an emergency service category for the CS domain" as described in 3GPP TS 23.167 [4B] triggering a normal call when the dialled number is available or triggering an emergency call when the dialled number is not available. The country specific URN is an example of a "emergency subservice type that does not map into an emergency service category for the CS domain".

When the emergency registration expires, the UE should disconnect the PDN connection for emergency bearer services as described in 3GPP TS 24.301 [8J].

Upon receiving a 3xx other than 380 (Alternative service), 4xx, 5xx or 6xx response to an INVITE request for a UE detectable emergency call, the UE shall perform domain selection as specified in 3GPP TS 23.167 [4B] annex H, to re-attempt the emergency call.

#### L.2.2.6.1A Type of emergency service derived from emergency service category value

The type of emergency service for an emergency number is derived from the settings of the emergency service category value (bits 1 to 5 of the emergency service category value as specified in subclause 10.5.4.33 of 3GPP TS 24.008 [8]). Table L.2.2.6.1 below specifies mappings between a type of emergency service and an emergency service URN. The UE shall use the mapping to match an emergency service URN and a type of emergency service. If a dialled number is an emergency number but does not map to a type of emergency service the service URN shall be "urn:service:sos".

**Table L.2.2.6.1: Mapping between type of emergency service and emergency service URN**

| Type of emergency service | Emergency service URN     |
|---------------------------|---------------------------|
| Police                    | urn:service:sos.police    |
| Ambulance                 | urn:service:sos.ambulance |
| Fire Brigade              | urn:service:sos.fire      |
| Marine Guard              | urn:service:sos.marine    |
| Mountain Rescue           | urn:service:sos.mountain  |

NOTE 1: It is not possible for a UE to indicate more than one type of emergency service in an emergency service URN.

If an IP-CAN, capable of providing local emergency numbers, did not provide a local emergency number that matches the dialled number (see subclause 5.1.6.1) and multiple types of emergency service can be derived for a dialled number from the information configured on the USIM then:

- if the UE is in the HPLMN, the UE shall map any one of these types of emergency service to an emergency service URN as specified in table L.2.2.6.1; and
- if the UE is in the VPLMN, the UE shall select "urn:service:sos".

NOTE 2: If the Non-3GPP emergency number indicator within the Non-3GPP NW provided policies IE (see 3GPP TS 24.008 [8]) provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers permitted", the UE also considers WLAN provided local emergency numbers (see 3GPP TS 24.302 [8U], subclause 4.7). If the Non-3GPP NW provided policies IE provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers not permitted", the UE does not consider WLAN provided local emergency numbers. If the Non-3GPP NW provided policies IE is not provided through registration procedures over 3GPP access, the UE does not consider WLAN provided local emergency numbers.

If an IP-CAN, capable of providing local emergency numbers, provided a local emergency number that matches the dialled number (see subclause 5.1.6.1), and:

- if the UE can derive one or more types of emergency service from the information received from the IP-CAN for the dialled number and the UE cannot derive types of emergency service from the information configured on the USIM for the dialled number; or
- if the UE is able to derive identical types of emergency service from both the information received from the IP-CAN for the dialled number and from the information configured on the USIM for the dialled number,

then the UE shall map any one of these emergency service types to an emergency service URN as specified in table L.2.2.6.1.

NOTE 3: How the UE resolves clashes where an emergency number is associated with one or more different types of emergency service configured in the USIM and in information received from the access network, is implementation dependent.

#### L.2.2.6.1B Type of emergency service derived from extended local emergency number list

The Extended Local Emergency Number List (defined in 3GPP TS 24.301 [8J]) can contain sub-services of the associated emergency service URN for the detected emergency number.

If:

- the length of sub-services field is greater than "0", the UE shall construct the emergency service URN using "urn:service:sos" followed by adding a dot followed by the content of the sub-services field; and
- the length of sub-services field is "0", the UE shall use the emergency service URN "urn:service:sos".

EXAMPLE 1: For a detected number, if the sub-service is "gas", then the UE constructs "urn:service:sos.gas" as the associated emergency service URN.

EXAMPLE 2: For a detected number, if no sub-service is provided, then the UE uses "urn:service:sos" as the associated emergency service URN.

#### L.2.2.6.2 eCall type of emergency service

If the IP-CAN indicates the eCall support indication or the CS domain is not available to the UE, the UE can send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

If the IP-CAN does not indicate the eCall support indication and the CS domain is available to the UE, the UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

### L.2.2.6.3 Current location discovery during an emergency call

Void.

---

## L.2A Usage of SDP

### L.2A.0 General

NOTE 1: When:

- establishing a session which is not an emergency session; or
- modifying a session which is not an emergency session;

and if the IMSVoPS indicator is received in the EPS network feature support information element (see 3GPP TS 24.301 [8J]) and no persistent EPS bearer context exists at the UE, the UE constructs SDP based on the restrictions indicated in the IMSVoPS indicator. Regardless whether the IMSVoPS indicator indicating voice is supported or not, m-lines can be set to "audio" and exclude voice codecs from the SDP answer or SDP offer. When a persistent EPS bearer context exists, m-lines can be set to "audio" and include voice codecs in the SDP answer or SDP offer.

NOTE 2: When the UE is accessing the IM CN subsystem via E-UTRAN, the appropriate specification for access domain selection is 3GPP TS 23.221 [6].

### L.2A.1 Impact on SDP offer / answer of activation or modification of EPS bearer context for media by the network

If, due to the activation of EPS bearer context from the network the related SDP media description needs to be changed, the UE shall update the related SDP information by sending, within a SIP request, a new SDP offer for each of the existing SIP dialogs,

If the UE receives a modification request from the network for a EPS bearer context that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) if, due to the modification of the EPS bearer context, the related SDP media description need to be changed, update the related SDP information by sending, within a SIP request, a new SDP offer for each of the existing SIP dialogs, and respond to the EPS bearer context modification request.

NOTE: The UE can decide to indicate additional media streams as well as additional or different codecs in the SDP offer than those used in the already ongoing session.

### L.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

If the UE receives an SDP offer where the SDP offer includes all media streams for which the originating side indicated its local preconditions as met, if the precondition mechanism is supported by the terminating UE and the IP-CAN performs network-initiated resource reservation for the terminating UE and the available resources are not sufficient for the received offer, the terminating UE shall indicate its local preconditions and provide the SDP answer to the originating side without waiting for resource reservation.

NOTE: If the resource reservation is controlled by the EPS IP-CAN, the resource reservation request is initiated by the network after the P-CSCF has authorised the respective IP flows and provided the QoS requirements over the Rx interface to the PCRF as described in 3GPP TS 29.214 [13D].

## L.2A.3 Emergency service

NOTE: When establishing an emergency session or when modifying an emergency session, the IMSVoPS indicator does not influence handling of SDP offer and SDP answer.

---

## L.3 Application usage of SIP

### L.3.1 Procedures at the UE

#### L.3.1.0 Registration and authentication

The UE shall perform reregistration of a previously registered public user identity bound to any one of its contact addresses when changing to an IP-CAN for which usage is specified in annex R or annex W. The reregistration is performed using the new IP-CAN.

NOTE 1: This document does not specify how the UE detects that the used IP-CAN has changed. The information that is forcing the reregistration is also used to generate the content for the P-Access-Network-Info header field.

NOTE 2: The UE will send the reregistration irrespective of whether it has a SIP dialog or not.

If the UE supports the 3GPP PS data off, then the UE shall in all REGISTER requests include the "+g.3gpp.ps-data-off" header field parameter defined in subclause 7.9.8 set to a value indicating the 3GPP PS data off status.

When the UE sends a REGISTER request, if the 3GPP PS data off status is "active", then the UE shall only include media feature tags associated with services that are 3GPP PS data off exempt services in the g.3gpp.icsi-ref media feature tag, as defined in subclause 7.9.2 and RFC 3840 [62], for the IMS communication services it intends to use.

If the UE is registered, and the 3GPP PS data off status is changed or the UE is provided by the network with a new list of 3GPP PS data off exempt services while the 3GPP PS data off status is "active", then the UE shall perform a reregistration of the previously registered public user identity.

A UE supporting ANBR as specified in 3GPP TS 26.114 [9B] shall also support RAN-assisted codec adaptation as specified in 3GPP TS 36.300 [268] and 3GPP TS 36.321 [269].

If the UE supports ANBR, upon receiving a 200 (OK) response to the REGISTER request and if the 200 (OK) response contains a Feature-Caps header field with the g.3gpp.anbr feature-capability indicator the UE shall assume that the network supports RAN-assisted codec adaptation as specified in 3GPP TS 36.300 [268] and 3GPP TS 36.321 [269]. The UE is allowed to include the SDP 'anbr' attribute during session establishment as specified in 3GPP TS 26.114 [9B].

#### L.3.1.0a IMS\_Registration\_handling policy

The IMS\_Registration\_handling policy indicates whether the UE deregisters from IMS after a configured amount of time after receiving an indication that the IMS Voice over PS Session is not supported.

The UE may support the IMS\_Registration\_handling policy.

If the UE supports the IMS\_Registration\_handling policy, the UE may support being configured with the IMS\_Registration\_handling policy using one or more of the following methods:

- a) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G].

If the UE is configured with both the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G] and the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file shall take precedence.

NOTE 1: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

If the UE is registered with IMS and the IMSVoPS indicator, provided by the lower layers (see 3GPP TS 24.301 [8J]), indicates voice is not supported, the UE shall:

- A) if the `Stay_Registered_When_VoPS_Not_Supported` leaf indicates requirement to stay registered, the UE needs not to deregister and maintains the registration as required for IMS services; or

NOTE 2: The UE will periodically refresh the registration when needed.

- B) if the `Stay_Registered_When_VoPS_Not_Supported` leaf indicates requirement to deregister and the `Deregistration_Timer` leaf used to configure the NoVoPS-dereg timer defined in table 7.8.1 contains a timer value for the time to wait before deregistering from IMS, start a timer with the value indicated in the policy and:
- a) if the timer expires before the UE receives an indication from the lower layers that IMS voice is supported:
    - 1) if there is no ongoing IMS session, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6; or
    - 2) if there is ongoing IMS session, and
      - i) if the UE does not receive indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6 as soon as the ongoing IMS based service is terminated; or
      - ii) if the UE receives indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, cancel the timer; or

NOTE 3: How the UE selects reregistration or deregistration is implementation dependent (e.g., SMS service)

- b) if the UE receives an indication from the lower layers that IMS voice is supported before the timer expires, cancel the timer.

If the `IMS_Registration_handling` policy is not configured, the UE behaviour is implementation specific.

### L.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

NOTE: If the P-Access-Network-Info header field includes radio cell identity, the P-Access-Network-Info header field populated by the UE that supports Multi-RAT Dual Connectivity with the EPC as described in 3GPP TS 37.340 [264] will contain the information about the radio cell identity of the Master RAN node that is serving the UE.

#### L.3.1.1A Cellular-Network-Info header field

Not applicable.

### L.3.1.2 Availability for calls

This subclause documents the minimal requirements for being available for voice communication services when using EPS.

A UE shall perform an initial registration as specified in subclause 5.1.1.2 using an EPS bearer context for SIP signalling (see annex L.2.2.1), if all the following conditions are met:

- 1) if the UE is operating in one of the following modes of operation (see 3GPP TS 24.301 [8J]):
  - a) PS mode 1;

- b) CS/PS mode 1 and the UE is attached for EPS-Services only;
- 2) if the UE is capable of receiving any (but not necessarily all) of the media types which the CS domain supports, such that the media type can also be used when accessing the IM CN subsystem using the current IP-CAN;
- 3) if:
  - a) the media type of item 2 is an "audio" media type
  - b) the UE supports codecs suitable for (conversational) speech; and
  - c) the "audio" media type is not restricted from inclusion in an SDP message according to the media type restriction policy as specified in subclause 6.1.1and one of the following is true:
  - a) 3GPP PS data off status is "inactive";
  - b) 3GPP PS data off status is "active", the UE is in the HPLMN or the EHPLMN, and MMTEL voice is a 3GPP PS data off exempt service; or
  - c) 3GPP PS data off status is "active", the UE is in the VPLMN, the UE is configured with an indication that MMTEL voice is a 3GPP PS data off exempt service in a VPLMN, and MMTEL voice is a 3GPP PS data off roaming exempt service.
- 4) if the UE determines that its contact has not been bound to a public user identity using the IP-CAN, such that the contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to the media of item 2 and item 3;
- 5) if the IMSVoPS indicator, provided by the lower layers (see 3GPP TS 24.301 [8J]), indicates voice is supported;
- 6) if the procedures to perform the initial registration are enabled (see 3GPP TS 24.305 [8T]); and
- 7) if the EPS bearer context used for SIP signalling is:
  - a) available; or
  - b) not available, and the UE:
    - i. is allowed to send a PDN CONNECTIVITY REQUEST message to establish an EPS bearer context that is needed for performing the initial registration; or
    - ii. is allowed to send a BEARER RESOURCE ALLOCATION REQUEST message, wishes to establish an EPS bearer with the correct QCI and TFT for performing the initial registration, and a default EPS bearer context for the APN exists.

NOTE 1: 3GPP TS 24.301 [8J] specifies conditions that prevent the UE from sending a PDN CONNECTIVITY REQUEST message or a BEARER RESOURCE ALLOCATION REQUEST message.

NOTE 2: Regardless of any of the above conditions, a UE might attempt to register with the IM CN subsystem at any time.

EXAMPLE: As an example of the note, a UE configured to preferably attempt to use the EPS to access IM CN subsystem can perform an initial registration as specified in subclause 5.1.1.2, if the conditions in items 2, 3, 4, 5, 6 and 7 in this subclause, evaluate to true.

The UE indicates to the non-access stratum the status of being available for voice over PS when:

- I) the UE is capable of receiving any (but not necessarily all) of the media types which the CS domain supports, such that the media type can also be used when accessing the IM CN subsystem using the current IP-CAN; II) if the media type of item I is an "audio" media type, the UE supports codecs suitable for (conversational) speech, the "audio" media type is not restricted from inclusion in an SDP message according to the media type restriction policy as specified in subclause 6.1.1, and:
  - a) 3GPP PS data off status is "inactive";

- b) 3GPP PS data off status is "active", the UE is in the HPLMN or the EHPLMN, and MMTEL voice is a 3GPP PS data off exempt service; or
- c) 3GPP PS data off status is "active", the UE is in the VPLMN, the UE is configured with an indication that MMTEL voice is a 3GPP PS data off exempt service in a VPLMN, and MMTEL voice is a 3GPP PS data off roaming exempt service; and

III) the UE determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media.

The UE indicates to the non-access stratum the status of being not available for voice over PS when:

- I) in response to receiving the IMSVoPS indicator indicating voice is supported, the UE:
  - initiated an initial registration as specified in subclause 5.1.1.2, received a final response to the REGISTER request sent, but the conditions for indicating the status of being available for voice over PS are not met; or
  - did not initiate an initial registration as specified in subclause 5.1.1.2 and, these conditions for indicating the status of being available for voice over PS are not met; or
- II) the conditions for indicating the status of being available for voice over PS are no longer met.

NOTE 3: The status of being not available for voice over PS is used for domain selection for UE originating sessions / calls specified in 3GPP TS 23.221 [6] subclause 7.2a.

### L.3.1.2A Availability for SMS

The UE determines that the UE is able to use SMS using IMS if the UE:

- I) is capable of using the MIME type "application/vnd.3gpp.sms" (see 3GPP TS 24.341 [8L]), such that the MIME type can also be used when accessing the IM CN subsystem using the current IP-CAN;
- II) supports the role of an SM-over-IP sender (see 3GPP TS 24.341 [8L]);
- IIA) determines the EPS bearer context used for SIP signalling exists;
- III) determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media;
- IV) the UE does not determine that SMS over IP is restricted in 3GPP TS 24.341 [8L] subclause 5.2.1.3; and
- V) the 3GPP PS data off status is:
  - "inactive";
  - "active", the UE is in the HPLMN or the EHPLMN, and SMS over IMS is a 3GPP PS data off exempt service; or
  - "active", the UE is in the VPLMN, the UE is configured with an indication that SMS over IMS is a 3GPP PS data off exempt service in a VPLMN, and SMS over IMS is a 3GPP PS data off roaming exempt service.

When above criteria are not matched, the UE determines that SMS using IMS is unavailable.

NOTE: The status that SMS using IMS is unavailable is used for domain selection for UE originating SMS specified in 3GPP TS 23.221 [6] subclause 7.2c.

### L.3.1.3 Authorization header field

Void.

### L.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Upon receiving an INVITE request not including the "precondition" option-tag in the Supported header field and not including the "precondition" option-tag in the Require header field, and the IP-CAN performs network-initiated resource reservation for the UE, the UE:

- 1) if the INVITE request contains an SDP offer and the local resources required at the terminating UE for the received SDP offer are not available:
  - a) shall not alert the user; and
  - b) shall send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. If the INVITE request includes a Supported header field indicating support of reliable provisional responses, the UE shall send the 183 (Session Progress) response reliably. In the 183 (Session Progress) response, the UE shall include an SDP answer; and
- 2) if the INVITE request does not contain an SDP offer and the INVITE request includes a Supported header field indicating support of reliable provisional responses:
  - a) shall generate an SDP offer;
  - b) if the local resources required at the terminating UE for the generated SDP offer are not available:
    - A) shall not alert the user; and
    - B) shall reliably send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. In the 183 (Session Progress) response, the UE shall include the generated SDP offer.

Upon successful reservation of local resources, if the precondition mechanism is not used by the terminating UE, the UE can send 180 (Ringing) response to the INVITE request and can alert the user.

### L.3.1.5 3GPP PS data off

If the 3GPP PS data off status is "active" the UE shall only send initial requests that:

- 1) are associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are associated with an emergency service;
- 3) are associated with access to RLOS; or
- 4) are associated with 3GPP PS data off exempt services configured in the UE using one or more of the following methods:
  - the non\_3GPP\_ICSI<sub>s</sub>\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSI<sub>s</sub>\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
  - the non\_3GPP\_ICSI<sub>s</sub>\_roaming\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the VPLMN;
  - the non\_3GPP\_ICSI<sub>s</sub>\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSI<sub>s</sub>\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
  - the non\_3GPP\_ICSI<sub>s</sub>\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the 3GPP PS data off status changes from "inactive" to "active" the UE shall release all dialogs that

- 1) are not associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are not associated with an emergency service; and
- 3) are not associated with 3GPP data off exempt services configured in the UE using one or more of the following methods:
  - the non\_3GPP\_ICSIIs\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
  - the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the VPLMN;
  - the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
  - the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

### L.3.1.6 Transport mechanisms

No additional requirements are defined.

### L.3.1.7 RLOS

#### L.3.1.7.1 General

The support for RLOS as described in this subclause is optional for the UE.

#### L.3.1.7.2 Registration

A UE containing a UICC on sending an unprotected REGISTER request for RLOS, shall perform the actions as specified in subclause 5.1.1.2 with the following additions:

- a) the UE shall in the REGISTER request include a "+g.3gpp.rlos" Contact header field parameter, as defined in subclause 7.9.9.

NOTE: The UE can choose to use initial registration using IMS AKA or initial registration using GPRS-IMS bundled authentication.

A UE not containing a UICC on sending an unprotected REGISTER request for RLOS shall perform the actions as specified in subclause 5.1.1.2 for registration using GPRS-IMS bundled authentication with the following additions:

- a) the UE shall generate a home network domain name according to the rules specified in 3GPP TS 23.003 [3] using the PLMN to which the UE is currently attached and set the Request-URI to the SIP URI of the so generated home network domain name;
- b) the UE shall include a To header field set to "[sip:unavailable@unknown.invalid](#)" (specified in 3GPP TS 23.003 [3]);
- c) the UE shall include a From header field set to "[sip:unavailable@unknown.invalid](#)" (specified in 3GPP TS 23.003 [3]); and
- d) the UE shall in the REGISTER request include a "+g.3gpp.rlos" Contact header field parameter, as defined in subclause 7.9.9

On reception of a 200 (OK) response to the REGISTER request for RLOS, the UE shall perform the actions as specified in subclause 5.1.1.2 and shall locally store an indication that RLOS session setup is possible. The indication is valid for an implementation specific time.

On receiving a 403 (Forbidden) response containing a Response-Source header field with a "fe" header field parameter set to "<urn:3gpp:fe:s-cscf>" for an initial registration that included a "+g.3gpp.rlos" Contact header field parameter in the REGISTER request, then the UE shall locally store an indication that setup of a RLOS session is possible. The indication is stored for an implementation dependent time.

### L.3.1.7.3 Session Setup

#### L.3.1.7.3.1 Void

#### L.3.1.7.3.2 RLOS session set-up in case of unsuccessful registration

The UE shall establish a RLOS session as described in this sub-clause only after it has initiated a RLOS registration and has received a 403 (Forbidden) response sent from an S-CSCF.

When establishing a RLOS session in case of an unregistered user, the UE is allowed to receive responses to RLOS requests and requests inside an established RLOS session on the unprotected ports. The UE shall reject or silently discard all other messages. Additionally, the UE shall transmit signalling packets pertaining to the RLOS session from the same IP address and unprotected port on which it expects to receive signalling packets containing the responses to RLOS requests and the requests inside the established RLOS session.

When establishing a RLOS session for an unregistered user, the UE shall use the local IP address and P-CSCF address as used when sending the RLOS registration. The UE shall send only the initial INVITE requests to the port advertised to the UE during the P-CSCF discovery procedure. If the UE does not receive any specific port information during the P-CSCF discovery procedure, the UE shall send the initial INVITE request to the SIP default port values as specified in RFC 3261 [26].

The UE shall apply the procedures as specified in subclause 5.1.2A.1 and subclause 5.1.3 with the following additions:

- 1) the UE shall set the From header field of the INVITE request to the public user identity as used in the RLOS registration;
- 2) the UE shall:
  - a) if a dial string for a specific RLOS service is available in the UE, use the dial string to build the Request-URI as specified in subclause 5.1.2A.1.3; and
  - b) if no dial string for a specific RLOS service is available in the UE use the dummy MSISDN value as defined in 3GPP TS 23.003 [3] to build the Request-URI as specified in subclause 5.1.2A.1.3;
- 3) the UE shall insert in the INVITE request, a To header field with the same value as in the Request-URI;

- 4) The UE shall insert a P-Preferred-Service header field according to RFC 6050 [121] set to "urn:urn-7:3gpp-service.ims.icsi.rlos";
- 5) The UE shall insert an Accept-Contact header field field containing the "+g.3gpp.icsi-ref" header field parameter containing an ICSI value set to "urn:urn-7:3gpp-service.ims.icsi.rlos";
- 6) the UE shall include in the P-Access-Network-Info header field in any request for a dialog, any subsequent request (except CANCEL requests) or response (except CANCEL responses) within a dialog or any request. Insertion of the P-Access-Network-Info header field into the ACK request is optional. The UE shall populate the P-Access-Network-Info header field with the current point of attachment to the IP-CAN as specified for the access network technology (see subclause 7.2A.4).;
- 7) The UE shall populate the P-Preferred-Identity header field in the INVITE request with an IMEI based identity in the form of a SIP URI as specified in 3GPP TS 23.003 [3] subclause 13.13;
- 8) a Contact header field set to include SIP URI that contains in the hostport parameter the IP address of the UE and an unprotected port where the UE will receive incoming requests belonging to this dialog. The UE shall also include a "sip.instance" media feature tag containing Instance ID as described in RFC 5626 [92]. The UE shall also include the "+g.3gpp.icsi-ref" header field parameter containing an ICSI value set to "urn:urn-7:3gpp-service.ims.icsi.rlos" . The UE shall not include either the public or temporary GRUU in the Contact header field;
- 9) a Via header field set to include the IP address of the UE in the sent-by field and for the UDP the unprotected server port value where the UE will receive responses, while for the TCP, the response is received on the TCP connection on which the RLOS request was sent. For the UDP, the UE shall also include "rport" header field parameter with no value in the top Via header field.;

NOTE 1: The UE inserts the same IP address and port number into the Contact header field and the Via header field, and sends all IP packets to the P-CSCF from this IP address and port number.

- 10) if the UE has its location information available, or a URI that points to the location information, the UE shall include a Geolocation header field in the INVITE request in the following way:
  - if the UE is aware of the URI that points to where the UE's location is stored, include the URI as the Geolocation header field value, as described in RFC 6442 [89]; or
  - if the UE is aware of its location information, include the location information in a PIDF location object, in accordance with RFC 4119 [90], include the location object in a message body with the content type application/pidf+xml, and include a Content ID URL, referring to the message body, as the Geolocation header field value, as described RFC 6442 [89], and include a Content-Disposition header field with a disposition type "render" value and a "handling" header field parameter with an "optional" value, as described in RFC 3261 [26];
- 11) if the UE includes a Geolocation header field, the UE shall also include a Geolocation-Routing header field with a "yes" header field value, which indicates that the location of the UE can be used by other entities to make routing decisions, as described in RFC 6442 [89]; and
- 12) if the UE has neither geographical location information available, nor a URI that points to the location information, the UE shall not insert a Geolocation header field in the INVITE request.

The UE shall build a proper preloaded Route header field value for all new dialogs. The UE shall build a Route header field value containing only the P-CSCF URI which was used in the RLOS registration.

When a SIP transaction times out, i.e. timer B, timer F or timer H expires at the UE, the UE may behave as if timer F expired, as described in subclause 5.1.1.4.

If the response for the initial INVITE request indicates that the UE is behind NAT, and the INVITE request was sent over TCP connection, the UE shall keep the TCP connection during the entire duration of the emergency session. In this case the UE will receive all responses to the emergency requests and the requests inside the established emergency session over this TCP connection.

If the Via header field of any provisional response, or of the final 200 (OK) response, for the initial INVITE request contains a "keep" header field parameter with a value, unless the UE detects that it is not behind a NAT, the UE shall start to send keep-alives associated with the session towards the P-CSCF, as described in RFC 6223 [143].

### L.3.1.7.3.3 RLOS session set-up in case of successful registration

The UE shall apply the procedures as specified in subclauses 5.1.2A and 5.1.3 with the following additions:

- 1) the UE shall include in the Request-URI of the initial INVITE request the dummy MSISDN value as defined in 3GPP TS 23.003 [3];
- 2) the UE shall insert in the INVITE request, a To header field with the same value as in the Request-URI;
- 3) The UE shall insert a P-Preferred-Service header field according to RFC 6050 [121] set to "urn:urn-7:3gpp-service.ims.icsi.rlos"; and
- 4) The UE shall insert an Accept-Contact header field field containing the "+g.3gpp.icsi-ref" header field parameter containing an ICSI value set to "urn:urn-7:3gpp-service.ims.icsi.rlos";

## L.3.2 Procedures at the P-CSCF

### L.3.2.0 Registration and authentication

Void.

#### L.3.2.1 Determining network to which the originating user is attached

If the P-CSCF is configured to handle emergency requests, in order to determine from which network the request was originated the P-CSCF shall check the MCC and MNC fields received:

- during the registration procedure from the Rx interface as defined in 3GPP TS 29.214 [13D] (e.g. used for deployments without IMS-level roaming interfaces where the P-CSCF is located in the home network); or
- from the P-Access-Network-Info header field.

NOTE: The above check can be against more than one MNC code stored in the P-CSCF.

#### L.3.2.2 Location information handling

Void.

#### L.3.2.3 Prohibited usage of PDN connection for emergency bearer services

If the P-CSCF detects that a UE uses a PDN connection for emergency bearer services for a non-emergency REGISTER request, the P-CSCF shall reject that request by a 403 (Forbidden) response.

NOTE: By assigning specific IP address ranges for a PDN connection for emergency bearer services and configuring those ranges in P-CSCF, the P-CSCF can detect based on the registered Contact address if UE uses an emergency PDN connection for initial registration.

#### L.3.2.4 Support for paging policy differentiation

The P-CSCF may support paging policy differentiation by marking packet(s) to be sent towards the UE related to that IMS capability. A specific DSCP (IPv4) value and/or a specific Traffic Class (IPv6) value are assigned by local configuration in the P-CSCF.

If local policy requires to provide such marking, the P-CSCF shall identify terminating requests which:

- a) contain SDP with an "audio" media line and which are related to a IMS multimedia telephony service session specified in TS 24.173 [8H]; or
- b) do not contain an SDP offer but some indication, e.g. a feature capability indicator, indicates that an "audio" media line that would meet network policy for such differentiation, could form part of the subsequent SDP offer.

NOTE 1: Precise details of such indications, if any, are subject to operator policy. Alternatively the operator policy can be to not preferentially page requests without an SDP offer.

For such identified requests:

- a) where an unreliable transport mechanism is used as the transport protocol for SIP, the P-CSCF shall mark packets containing an INVITE request; and
- b) if a reliable transport mechanism is used as the transport protocol for SIP:
  - 1) if a new reliable transport connection needs to be established, the P-CSCF shall turn on the marking of packets within the reliable transport connection in advance of sending an INVITE request; and
  - 2) if there is an existing reliable transport connection, the P-CSCF may turn on the marking of packets within the reliable transport connection in advance of sending an INVITE request.

In both these cases for a reliable transport connection, the P-CSCF shall turn off the marking of packets within the reliable transport connection at an appropriate time.

### L.3.2.5 Void

### L.3.2.6 Resource sharing

#### L.3.2.6.1 Registration

If PCC is supported for this access technology a P-CSCF supporting resource sharing shall insert a Resource-Share header field with the value set to "supported" as described in subclause 7.2.13 and perform the actions in the following subclauses.

#### L.3.2.6.2 UE-originating case

Upon receiving an initial INVITE request from a served UE, if the P-CSCF supports resource sharing and local policy requires that resources are reserved already on the SDP offer in the initial INVITE request, the P-CSCF can:

- 1) for each m-line in the SDP offer, internally generate a set of temporary resource sharing rules where:
  - a) if the media line is not subject to resource sharing according to local policies, each resource sharing rule contains a sharing key with a value that is unique and not used by any another media stream in any ongoing session involving the UE;
  - b) directionality is included according to local policy; and
  - c) if the media line is subject to resource sharing according to local policies, each resource sharing rule contains a sharing key with the value as assigned to other ongoing media stream(s) of some ongoing session(s) involving the UE that also use the shared resources; and
- 2) apply resource-sharing as specified in 3GPP TS 29.214 [13D] using the temporary resource sharing rules.

When the P-CSCF supporting resource receives a 18x response or a 2xx response containing the initial SDP answer, a Resource-Share header field with the value "media-sharing" and the "origin" header field parameter set to "session-initiator", the P-CSCF:

- 1) shall store resource sharing rules and the value of the corresponding sharing key as described in subclause 7.2.13.5 and use the stored sharing keys to identify resource sharing rules for the media streams in this session; and
- 2) will apply resource sharing as specified in 3GPP TS 29.214 [13D] using the stored sharing rules.

NOTE 1: If a Resource-Share header field containing the same stored sharing key values and updated resource sharing rules are received in any other session involving the served UE, the updated resource sharing rules overrides the resource sharing rules received in this session.

If P-CSCF supports resource sharing and when the first response to the initial INVITE request (with the exception of the 100 (Trying) response) contains a Resource-Share header field with the value "no-media-sharing" and the "origin" header field parameter set to the value "session-initiator", the P-CSCF shall not share media in this session.

NOTE 2: When resource sharing is not possible, sharing keys identifying the temporary set of resource sharing rules used over the Rx interface if resources were reserved using the SDP offer can still be kept but can never be used in any other session involving this UE as long as this session is ongoing.

If P-CSCF supports resource sharing and when the first response to the initial INVITE request (with the exception of the 100 (Trying) response) containing the initial SDP answer does not contain a Resource-Share header field, the P-CSCF may apply resource sharing using local configuration.

### L.3.2.6.3 UE-terminating case

#### L.3.2.6.3.1 The initial INVITE request contains an initial SDP offer

If P-CSCF supports resource sharing and when P-CSCF receives an initial INVITE request destined to the served user containing the Resource-Share header field parameter with the value "media-sharing" and the "origin" header field parameter set to the value "session-receiver" and if local policy requires resource reservation using the initial SDP offer the P-CSCF shall:

- 1) store resource sharing rules and corresponding sharing key values as described in subclause 7.2.13.5 and use each stored sharing key to identify resource sharing rules for media streams in this session; and
- 2) apply resource sharing as specified in 3GPP TS 29.214 [13D] using the stored resource sharing rules.

NOTE: If a Resource-Share header field containing the stored sharing key are received in any other session involving the served UE, the updated resource sharing rules overrides the resource sharing rules received in this session.

Upon receiving a response to the above INVITE request containing an initial SDP answer, if the initial INVITE request containing the initial SDP offer contained the Resource-Share header field set to the value "media-sharing" and the "origin" header field parameter set to "session-receiver" and if local policy requires resource reservation on the initial SDP answer, the P-CSCF shall:

- 1) store resource sharing rules and corresponding sharing key values as described in subclause 7.2.13.5 and use the stored sharing keys to identify resource sharing rules for media streams in this session; and
- 2) apply resource sharing as specified in 3GPP TS 29.214 [13D] using the stored resource sharing rules.

If P-CSCF supports resource sharing and when P-CSCF receives an initial INVITE request containing the Resource-Share header field with the value "no-media-sharing" and the "origin" header field parameter set to the value "session-receiver", the P-CSCF shall not share media in this session.

If P-CSCF supports resource sharing and when P-CSCF receives an initial INVITE request not containing a Resource-Share header field, the P-CSCF may apply resource sharing using local configuration.

If the P-CSCF supporting resource sharing receives a request or response from the home network destined to the served user containing a Resource-Share header field with the "origin" header field parameter set to the value "session-initiator" or without the "origin" header field parameter, the P-CSCF shall not use the content of the header field and remove the header field from the outgoing response or request.

#### L.3.2.6.3.2 The 18x response or the 2xx responses contains an initial SDP offer

When the P-CSCF supporting resource sharing receives an 18x response or a 2xx response from a served UE and the response contains an initial SDP offer and local policy requires resource reservation using the initial SDP offer, the P-CSCF shall :

- 1) for each m-line in the SDP offer, internally generate a set of temporary resource sharing rules where:
  - each resource sharing rule contains a sharing key with a value that is unique and not used by any another media stream in any ongoing session involving the UE; and
  - directionality is included according to local policy; and

- 2) apply resource-sharing as specified in 3GPP TS 29.214 [13D] using the temporary resource sharing rules.

Upon receiving a PRACK request or an ACK request containing the initial SDP answer and a Resource-Share header field with the value "media-sharing" and the "origin" header field parameter set to "session-receiver", the P-CSCF shall:

- 1) store resource sharing rules and the value of the corresponding sharing key as described in subclause 7.2.13.5 and use stored sharing key to identify resource sharing rules for the media streams in this session; and
- 2) apply resource sharing rules as specified in 3GPP TS 29.214 [13D] using the stored sharing rules.

Upon receiving a PRACK request or an ACK request containing the initial SDP answer and a Resource-Share header field with the value "no-media-sharing", the P-CSCF shall not share resources in this session.

NOTE: If resources can't be shared the temporary set of resource sharing rules used over Rx interface when reserving resources using the initial SDP offer can still be kept but can never be used in any other session involving this UE as long as this dialog is ongoing.

Upon receiving a PRACK request or an ACK request containing the initial SDP answer and the response does not contain a Resource-Share header field, the P-CSCF may apply resource sharing using local configuration.

#### L.3.2.6.4 Abnormal cases

If P-CSCF receives a request or response from the served UE and there is a conflict with the given instructions over Rx and the UE behaviour, the P-CSCF shall:

- immediately stop resource sharing for all media streams in this session as described in 3GPP TS 29.214 [13D]; and
- if resource sharing options is determined by an AS, include the Resource-Share header field set to the value "no-media-sharing" along with the "origin" header field set to "session-initiator" or "session-receiver" as appropriate in the outgoing request or response.

NOTE 1: How P-CSCF detects that there is a conflict with the given instruction over Rx and the UE behaviour is implementation dependent and not further described.

NOTE 2: A typical example of a conflict between a given instruction over Rx and the UE behaviour is if media sharing is allowed in both uplink and downlink direction and if in the communication waiting use case, the UE sends a 200 (OK) response to the INVITE request without putting the first call on hold. The UE's behaviour is then regarded as unpredictable and resource sharing cannot be used for any session using the stored sharing key value involving that UE.

The P-CSCF shall remove the Resource-Share header field from the request or response received from a served user.

#### L.3.2.6.5 Resource sharing options updated by AS

At any point in an ongoing session the AS in the home network can include in an subsequent request or response a Resource-Share header field containing updated resource sharing options and when such an update is received the P-CSCF shall store the new sharing rules as described in subclause 7.2.13.8.4 and apply any change as described in 3GPP TS 29.214 [13D].

### L.3.2.7 Priority sharing

#### L.3.2.7.1 General

If P-CSCF supports priority sharing, PCC is supported for this access technology and if according to operator policy, the P-CSCF shall apply the procedures in the following subclauses.

If P-CSCF supports priority sharing, the P-CSCF shall remove the Priority-Share header field from outgoing requests or responses destined to the served UE.

### L.3.2.7.2 Registration procedure

The P-CSCF supporting priority sharing and if according to operator policy shall include the `g.3gpp.priority-share` feature-capability indicator defined in subclause 7.9A.10 in a Feature-Caps header field in the SIP REGISTER request.

### L.3.2.7.3 Session establishment procedure

When receiving the Priority-Share header field defined in subclause 7.2.16 in an initial INVITE request or in a 18x or a 2xx response to the initial INVITE request destined to the served UE and if according to operator policy, the P-CSCF shall apply priority sharing according to 3GPP TS 29.214 [13D] based on the value of the Priority-Share header field.

### L.3.2.7.4 Subsequent request procedure

When receiving the Priority-Share header field in a re-INVITE request, in a 18x or in a 2xx responses to the re-INVITE request destined to the served UE and if according to operator policy, the P-CSCF shall apply priority sharing according to 3GPP TS 29.214 [13D] based on the value of the Priority-Share header field.

When receiving the Priority-Share header field in an subsequent request or in a 2xx responses to the subsequent request destined to the served UE and if according to operator policy, the P-CSCF shall apply priority sharing according to 3GPP TS 29.214 [13D], based on the value of the Priority-Share header field.

## L.3.2.8 RLOS

### L.3.2.8.1 General

The support for RLOS as described in this subclause is optional for the P-CSCF.

### L.3.2.8.2 Registration

A P-CSCF supporting RLOS shall perform the procedures as specified in subclause 5.2.2 and in addition shall perform the procedures specified in this subclause.

When the P-CSCF receives a REGISTER request from the UE, the P-CSCF shall:

- 1) the REGISTER request contains a "+g.3gpp.rlos" Contact header field parameter:
  - a) if the P-Access-Network-Info header field indicates an IP-CAN for which procedures are defined in an Annex different than Annex L the P-CSCF shall reject the REGISTER request by sending a 403 (Forbidden) response;
  - b) based on the outcome of the IP address and APN check with the PCRF as described in 3GPP TS 23.228 [7] the P-CSCF may reject the REGISTER request by sending a 403 (Forbidden); and
  - c) The P-CSCF shall include a Response-Source header field with a "fe" header field parameter set to "<urn:3gpp:fe:p-cscf.orig>"; and
- 2) if the REGISTER request contains a "+g.3gpp.rlos" Contact header field parameter and the public user identity in the REGISTER request indicates a user for which the operator of the P-CSCF does not have a roaming agreement, select a preconfigured S-CSCF and insert a Route header field with the S-CSCF URI for originating requests and forward the request to the selected S-CSCF.

When the P-CSCF receives a 403 (Forbidden) response to a REGISTER request that contained a "+g.3gpp.rlos" Contact header field parameter, the P-CSCF shall:

- 1) create a temporary unauthenticated subscriber record for the registered public user identity;
- 2) associate the S-CSCF with the registered public user identity and associated contact address;
- 3) store the registered public user identity as a default public user identity for use with procedures for the P-Asserted-Identity header field for requests received from the UE;
- 4) store the values received in the P-Charging-Function-Addresses header field;

- 5) if a "term-ioi" header field parameter is received in the P-Charging-Vector header field, store the value of the received "term-ioi" header field parameter; and

NOTE: Any received "term-ioi" header field parameter will contain a type 1 IOI. The type 1 IOI identifies the home network of the registered user.

- 6) void.

### L.3.2.8.3 Session Setup

#### L.3.2.8.3.1 General

If the P-CSCF supports RLOS, the P-CSCF shall accept unprotected requests on the IP address and the unprotected port advertised to the UE during the P-CSCF discovery or the SIP default port.

When the P-CSCF sends unprotected responses to the UE, it shall use the same IP address and port where the corresponding request was received.

#### L.3.2.8.3.2 General treatment for RLOS session setup – requests from an unregistered user

If the P-CSCF receives an initial request for a dialog or standalone transaction, or an unknown method from an unregistered user on the IP address and the unprotected port advertised to the UE during the P-CSCF discovery or the SIP default port,

The P-CSCF shall inspect the Request-URI independent of values of possible entries in the received Route header fields for the presence of the dummy MSISDN or a RLOS service specific dial string. The P-CSCF shall consider the Request URI of the initial request as indicating RLOS, if the Request-URI contains the dummy URI or a RLOS service specific dial string and if the request contains a P-Preferred-Service header field according to RFC 6050 [121] set to "urn:urn-7:3gpp-service.ims.icsi.rlos".

If the P-CSCF detects that the initial request for a dialog or a standalone transaction, or an unknown method indicates RLOS, and the P-CSCF has previously stored a temporary unauthenticated subscriber record for the public user identity contained in the From header field of the request:

- 1) shall include a topmost Route header field set to the URI of the S-CSCF as stored in the unauthenticated subscriber record;

NOTE 2: How the list of E-CSCF is obtained by the P-CSCF is implementation dependent.

- 2) shall execute the procedure described in subclause 5.2.6.3.3, subclause 5.2.6.3.7, subclause 5.2.6.3.11 and subclause 5.2.7.2, as appropriate except for:

- verifying the preloaded route against the received Service-Route header field;
- routing to IBCF; and
- inserting a type 1 "orig-ioi" header field parameter in the P-Charging-Vector header field;

- 3) shall insert a P-Asserted-Identity header field set to the public user identity as stored in the unauthenticated subscriber record; and

- 4) if the P-CSCF detects that the UE is behind a NAT, and the UE's Via header field contains a "keep" header field parameter, shall add a value to the parameter, to indicate that it is willing to receive keep-alives associated with the dialog from the UE, as defined in RFC 6223 [143].

When the P-CSCF receives any 1xx or 2xx response to the above requests, the P-CSCF shall execute the appropriate procedure for the type of request described in subclause 5.2.6.3.4, subclause 5.2.6.3.8, and subclause 5.2.6.3.12, except that the P-CSCF may rewrite the port number of its own Record-Route entry to an unprotected port where the P-CSCF wants to receive the subsequent incoming requests from the UE belonging to this dialog.

When the P-CSCF receives a target refresh request from the UE for a dialog, the P-CSCF shall execute the procedure described in subclause 5.2.6.3.5, except for inserting a type 1 "orig-ioi" header field parameter in the P-Charging-Vector header field.

When the P-CSCF receives from the UE subsequent requests other than a target refresh request (including requests relating to an existing dialog where the method is unknown), the P-CSCF shall execute the procedure described in subclause 5.2.6.3.9, except for inserting a type 1 "orig-voi" header field parameter in the P-Charging-Vector header field.

When the P-CSCF receives any 1xx or 2xx response to the above requests, the P-CSCF shall execute the appropriate procedure for the type of request described in subclause 5.2.6.3.5 or subclause 5.2.6.3.9.

#### L.3.2.8.3.3 General treatment for RLOS session setup – requests from a registered user

The P-CSCF shall follow procedures specified subclause 5.2.6.

### L.3.2.9 Support of ANBR and RAN-assisted codec adaptation

If the network supports ANBR as specified in 3GPP TS 26.114 [9B] and RAN-assisted codec adaptation as specified in 3GPP TS 36.300 [268] and 3GPP TS 36.321 [269], then the P-CSCF might be configured to indicate ANBR support.

If the P-CSCF is configured to indicate ANBR support, when the P-CSCF receives the 200 (OK) response to the REGISTER request the P-CSCF shall include the "g.3gpp.anbr" feature-capability indicator in the Feature-Caps header field of the 200 (OK) response to the REGISTER request.

## L.3.3 Procedures at the S-CSCF

### L.3.3.1 Notification of AS about registration status

Not applicable.

### L.3.3.2 RLOS

#### L.3.3.2.1 General

The support for RLOS as described in this subclause is optional.

#### L.3.3.2.2 Registration

A S-CSCF supporting RLOS shall perform the procedures as specified in subclause 5.4.1.2 and in addition shall perform the procedures specified in this subclause.

Upon receipt of a REGISTER request that is part of an initial registration as described in subclause 5.4.1.2.1

- 1) if REGISTER request contains a "+g.3gpp.rlos" Contact header field parameter, the S-CSCF:
  - a) if the S-CSCF supports GPRS-IMS-Bundled authentication and the public user identity in the REGISTER request indicates a user for which the operators of the S-CSCF does not have a roaming agreement with the home network operator, shall reject the request by returning a 420 (Bad Extension) response in which the Unsupported header field contains the value "sec-agree"; and
  - b) if the S-CSCF does not support GPRS-IMS-Bundled authentication and the public user identity in the REGISTER request indicates a user for which the operators of the S-CSCF does not have a roaming agreement with the home network operator, shall reject the request by returning a 403 (Forbidden) response and include a Response-Source header field with a "fe" header field parameter set to "<urn:3gpp:fe:s-cscf>". The S-CSCF shall create a temporary record for the public user identity which is registered with a default service profile which is valid for an implementation specific time; and

Upon receipt of a REGISTER request without an Authorization header field as described in subclause 5.4.1.2.1E and the REGISTER request contains a "+g.3gpp.rlos" Contact header field parameter, the S-CSCF shall skip the procedures in subclause 5.4.1.2.1E and shall

- 1) identify the user by the public user identity as received in the To header field of the REGISTER request. The S-CSCF shall derive the private user identity from the public user identity being registered by removing URI

scheme and the following parts of the URI if present: port number, URI parameters, and To header field parameters;

- 2) check if the P-Visited-Network-ID header field is included in the REGISTER request, and if it is included identify the visited network by the value of this header field;
- 3) check whether a "received" header field parameter exists in the Via header field provided by the UE. If a "received" header field parameter exists, the S-CSCF shall compare the IP address recorded in the "received" header field parameter against the UE's IP address stored during registration. In case of IPv6 stateless autoconfiguration, the S-CSCF shall compare the prefix of the IP address recorded in the "received" header field parameter against the UE's IP address prefix stored during registration. If no "received" header field parameter exists in the Via header field provided by the UE, then the S-CSCF shall compare IP address recorded in the "sent-by" parameter against the stored UE IP address. In case of IPv6 stateless autoconfiguration, S-CSCF shall compare the prefix of the IP address recorded in the "sent-by" parameter against the UE's IP address prefix stored during registration. In any case, if the stored IP address (or prefix) and the (prefix of the) IP address recorded in the Via header field provided by the UE do not match, the S-CSCF shall query the HSS as described in 3GPP TS 29.228 [14] with the derived private user identity and the public user identity as input and store the received IP address (or prefix) of the UE. If the stored IP address (or prefix) and the (prefix of the) IP address recorded in the Via header field provided by the UE still do not match the S-CSCF shall reject the registration with a 403 (Forbidden) response and skip the following steps;
- 4) determine the duration of the registration by checking the registration expiration interval value in the received REGISTER request and bind it either to the respective contact address of the UE or to the registration flow and the associated contact address (if the multiple registration mechanism is used). Based on local policy, the S-CSCF may reduce the duration of the registration or send back a 423 (Interval Too Brief) response specifying the minimum allowed time for registration;
- 5) update registration bindings;
- 6) create a temporary record for the public user identity being registered with a default service profile;
- 7) store the "icid-value" header field parameter received in the P-Charging-Vector header field;
- 8) if an "orig-ioi" header field parameter is received in the P-Charging-Vector header field, store the value of the received "orig-ioi" header field parameter;
- 9) check whether a Path header field was included in the REGISTER request and construct a list of preloaded Route header fields from the list of entries in the received Path header field. The S-CSCF shall preserve the order of the preloaded Route header fields and bind them either to the contact address of the UE and the contact information that was received in the REGISTER request; and
- 10) create and send a 200 (OK) response for the REGISTER request as specified in subclause 5.4.1.2.2F;

In case the timer reg-await-auth is running for this user, S-CSCF supports RLOS as specified in TS 23.228 [7] and the REGISTER request contains a "+g.3gpp.rlos" Contact header field parameter, the S-CSCF shall:

- 1) check if the Call-ID of the request matches with the Call-ID of the 401 (Unauthorized) response which carried the last challenge. The S-CSCF shall only proceed further if the Call-IDs match;
- 2) stop timer reg-await-auth;
- 3) check whether an Authorization header field is included, containing:
  - a) the private user identity of the user in the "username" header field parameter;
  - b) if the "integrity-protected" header field parameter is set to "yes", the "algorithm" header field parameter set to "AKAv1-MD5"
  - c) if the "integrity-protected" header field parameter is set to "tls-connected", the "algorithm" header field parameter set to "AKAv2-SHA-256" if the S-CSCF supports the IMS AKA using HTTP Digest AKAv2 without IPsec security association; and
  - d) the authentication challenge response needed for the authentication procedure in the "response" header field parameter.

The S-CSCF shall only proceed with the following steps in this paragraph if the authentication challenge response was included;

- 4) check whether the received authentication challenge response and the expected authentication challenge response (calculated by the S-CSCF using XRES and other parameters as described in RFC 3310 [49] when AKAv1 is used or as described in RFC 4169 [227] when AKAv2 is used) match. The XRES parameter was received from the HSS as part of the Authentication Vector. The S-CSCF shall only proceed with the following steps if the challenge response received from the UE and the expected response calculated by the S-CSCF do not match;
- 5) if there are public user identities (including the public user identity being registered, if previously registered) that belong to this user that have been previously registered with the same private user identity, and with an old contact address different from the one received in the REGISTER request and if the previous registrations have not expired:
  - a) terminate all dialogs, associated with the previously registered public user identities (including the public user identity being registered, if previously registered), with a status code 480 (Temporarily Unavailable) in the Reason header field of the BYE request, as specified in subclause 5.4.5.1.2;
  - b) send a NOTIFY request, to the subscribers to the registration event package of the previously registered public user identities, that indicates that all previously registered public user identities (excluding the public user identity being registered) belonging to this user identified with its private user identity, have been deregistered, as described in subclause 5.4.2.1.2. For the public user identity being registered, the NOTIFY request contains the new contact information; and
  - c) delete all information associated with the previously registered public user identities;
- 6) store the following information in the local data:
  - a) the public user identities due to the received REGISTER request which is set to the public user identity as received in the REGISTER request. The public user identity is identified as non-barred;
  - b) a default service profile that indicates that the public user identity is registered for RLOS;
  - c) if S-CSCF restoration procedures are supported, the restoration information if received as specified in 3GPP TS 29.228 [14]; and
  - d) if PCRF based P-CSCF restoration procedures are supported, all the user profile(s) corresponding to the public user identities being registered (explicitly or implicitly), including the IMSI, if available;
- 7) update registration bindings and
  - a) bind to each non-barred registered public user identity the registered contact information including all header field parameters contained in the Contact header field and all associated SIP URI parameters, and
  - b) if the Contact header field of the REGISTER request contained a "+sip.instance" and a "reg-id" header field parameter, and the SIP URI in the Path header field inserted by the P-CSCF contained an "ob" SIP URI parameter header field, and:
    - if the public user identity has not previously been registered with the same "+sip.instance" and "reg-id" Contact header field parameter values, then create the registration flow in addition to any existing registration flow; or
    - if the public user identity has previously been registered with the same "+sip.instance" and "reg-id" header field parameter values, then determine whether the request refreshes or replaces an existing registration flow. If the request:
      - i) refreshes an existing registration flow, then the S-CSCF shall leave the flow intact; or
      - ii) replaces the existing registration flow with a new flow, then the S-CSCF shall:
        - a) terminate any dialog, as specified in subclause 5.4.5.1.2, with a status code 480 (Temporarily Unavailable) in the Reason header field of the BYE request, associated with the registration flow being replaced; and

- b) send a NOTIFY request to the subscribers to the registration event package for the public user identity indicated in the REGISTER request, as described in subclause 5.4.2.1.2;
- 8) check whether a Path header field was included in the REGISTER request and construct a list of preloaded Route header fields from the list of entries in the received Path header field. The S-CSCF shall preserve the order of the preloaded Route header fields and bind them either to the contact address of the UE or the registration flow and the associated contact address (if the multiple registration mechanism is used) and the contact information that was received in the REGISTER request;
- 9) determine the duration of the registration by checking the value of the registration expiration interval value in the received REGISTER request and bind it either to the respective contact address of the UE or to the registration flow and the associated contact address (if the multiple registration mechanism is used). Based on local policy, the S-CSCF may reduce the duration of the registration or send back a 423 (Interval Too Brief) response specifying the minimum allowed time for registration.;
- 10) store the "icid-value" header field parameter received in the P-Charging-Vector header field;
- 11) if an "orig-ioi" header field parameter is received in the P-Charging-Vector header field, store the value of the received "orig-ioi" header field parameter; and
- 12) create a 403 (Forbidden) response for the REGISTER request including a Response-Source header field with a "fe" header field parameter set to "<urn:3gpp:fe:s-cscf >" and send the so generated response.

### L.3.3.2.3 Session Setup

#### L.3.3.2.3.1 General

A S-CSCF supporting RLOS shall perform the procedures as specified in subclause 5.4.3.2 and in addition shall perform the procedures specified in this subclause.

When the S-CSCF receives from the served user from an initial request for a dialog or a request for a standalone transaction and performing the procedures in subclause 5.4.3.2 and:

- 1) if there is no original dialog identifier that the S-CSCF previously placed in a Route header field is present in the topmost Route header field of the incoming request; and
- 2) if the Request-URI contains the dummy MSISDN value as defined in 3GPP TS 23.003 [3] or a RLOS service specific dial string and a P-Preferred-Service header set to "urn:urn-7:3gpp-service.ims.icsi.rlos" is included in the request;

the S-CSCF shall build an ordered list of initial filter criteria based on the temporary unauthenticated subscriber record for the public user identity of the served user instead of building the ordered list of initial filter criteria as described in bullet 3).

---

## L.4 3GPP specific encoding for SIP header field extensions

### L.4.1 Void

---

## L.5 Use of circuit-switched domain

There is no CS domain in this access technology.

NOTE 1: If the UE sends an INVITE request including voice codecs which is not successful due to a failure from the lower layers indicating that access is barred for originating calls but not specific to CSFB (see 3GPP TS 24.301 [8J]) and if the CS domain is supported and available, the UE can attempt the voice call via the CS domain.

NOTE 2: If the UE has sent an INVITE request including voice codecs, receives a 500 (Server Internal Error) response to this INVITE request containing no Retry-After header field, including a Reason header field with a protocol value set to "FAILURE\_CAUSE" including a cause value header field parameter set to "1" as specified in subclause 7.2A.18.12.2, a Response-Source header field with a "fe" header field parameter set to "<urn:3gpp:fe:p-cscf.orig>", and the UE is attached to both PS and CS domains, the UE can attempt the voice call via the CS domain, e.g. by initiating a service request for CS fallback (see 3GPP TS 24.301 [8J]).

---

# Annex M (normative): IP-Connectivity Access Network specific concepts when using cdma2000<sup>®</sup> packet data subsystem to access IM CN subsystem

## M.1 Scope

This annex defines IP-CAN specific requirements for call control protocol for use in the IM CN subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is the cdma2000<sup>®</sup> packet data subsystem. It also defines procedures for invoking CS domain services.

---

## M.2 cdma2000<sup>®</sup> packet data subsystem aspects when connected to the IM CN subsystem

### M.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the cdma2000<sup>®</sup> packet data subsystem to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this subclause. Requirements for the IP-CAN bearer control point (i.e. the point where the UE has attached itself to the cdma2000<sup>®</sup> packet data subsystem) support of this communication are specified in 3GPP2 X.S0011-E [127].

### M.2.2 Procedures at the UE

#### M.2.2.1 Establishment of IP-CAN bearer and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall:

- a) establish a connection with the cdma2000<sup>®</sup> wireless IP network specified in 3GPP2 X.S0011-E [127]. Upon establishment a connection with the cdma2000<sup>®</sup> wireless IP network, the UE can have an IPv4 address only, an IPv6 address only, or both IPv4 and IPv6 addresses simultaneously;
- b) ensure that an IP-CAN bearer used for SIP signalling is available. This IP-CAN bearer shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the last deregistration;

The UE shall choose one of the following options when performing establishment of this IP-CAN bearer:

I. A dedicated IP-CAN bearer for SIP signalling:

The UE shall indicate to the IP-CAN bearer control point that this is an IP-CAN bearer intended to carry IM CN subsystem-related signalling only. The UE may also use this IP-CAN bearer for DNS and DHCP access.

II. A general-purpose IP-CAN bearer:

The UE may decide to use a general-purpose IP-CAN bearer to carry IM CN subsystem-related signalling. The UE may carry both signalling and media on the general-purpose IP-CAN bearer; and

- c) discover a P-CSCF.

The methods for P-CSCF discovery are:

- I. Use DHCP mechanism
- II Retrieve the list of P-CSCF address(es) stored in the IMC
- III Obtain the list of P-CSCF address(es) from the IMS management object

The UE can freely select method I, II, or III for P-CSCF discovery. If DHCP is used, the following procedures apply:

Upon establishing an IP-CAN bearer, the UE may use the Dynamic Host Configuration Protocol (DHCP) specified in RFC 2131 [40A] or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) specified in RFC 3315 [40] to discover the P-CSCF.

Prior to accessing the DHCP server, the UE will have obtained an IP address via means other than DHCP and DHCPv6, see 3GPP2 X.S0011-E [127].

If the UE uses DHCP for P-CSCF discovery and the UE is unaware of the address of the DHCP server, the UE shall send the DHCPINFORM using the limited broadcast IP address (i.e., 255.255.255.255) and UDP port 67. If the UE knows the IP address of the DHCP server, the UE shall send the DHCPINFORM to the DHCP server's unicast IP address and UDP port 67. The DHCP server shall send the DHCPACK on the IP address specified in the Client IP Address field of the DHCPINFORM. The DHCP server may include, in the DHCPACK, the SIP Server DHCP Option specified in RFC 3361 [35A], which carries either a list of IPv4 address(es) of the P-CSCF(s) or a list of DNS fully qualified domain name(s) that can be mapped to one or more P-CSCF(s). If the UE uses DHCPv6 for P-CSCF discovery and the UE is unaware of the address of the DHCP Server, the UE shall send an Information Request using the IPv6 multicast address FF02::1:2 and the UDP port 547. If the UE knows the IP address of the DHCPv6 server, the UE shall send the Information Request message to the DHCPv6 server's IP address and UDP port 547. In the Information Request, the UE may request either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option specified in RFC 3319 [41]. The DHCP server shall send the Reply to the IP address specified in the Information Request. The DHCP server may include in the Reply either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option, as requested by the UE.

In case several P-CSCF's IP addresses or domain names are provided to the UE, the UE shall perform P-CSCF selection according to RFC 3361 [35A] or RFC 3319 [41]. The UE shall perform the procedure for the resolution of domain name according to RFC 3263 [27A].

### M.2.2.1A Modification of IP-CAN used for SIP signalling

Not applicable.

### M.2.2.1B Re-establishment of the IP-CAN used for SIP signalling

Not applicable.

### M.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure uses the keep-alive procedures described in RFC 6223 [143].

If the P-CSCF fails to respond to the keep-alive request the UE shall acquire a different P-CSCF address using any of the methods described in the subclause M.2.2.1 and perform an initial registration as specified in subclause 5.1.

### M.2.2.2 Void

### M.2.2.3 IP-CAN bearer control point support of DHCP based P-CSCF discovery

The IP-CAN bearer control point, or Home Agent in case of Mobile IP with reverse tunneling, may forward the packet to one or more local DHCP servers, or relay the packet to a specific DHCP server. The IP-CAN bearer control point, or Home Agent in case of Mobile IP with reverse tunnelling, shall not forward the DHCPINFORM (or Information-Request) to any UE.

NOTE 1: For forwarding the DHCPINFORM or Information-Request, the IP-CAN bearer control point, or Home Agent in case of Mobile IP with reverse tunnelling, does not change the destination IP address of the packet.

NOTE 2: For relaying the DHCPINFORM or Information-Request, the IP-CAN bearer control point, or Home Agent in case of Mobile IP with reverse tunnelling inserts a DHCP server's IP address in the destination IP address field of the packet.

## M.2.2.4 Void

## M.2.2.5 Handling of the IP-CAN for media

### M.2.2.5.1 General requirements

Not applicable.

#### M.2.2.5.1A Activation or modification of IP-CAN for media by the UE

Not applicable.

#### M.2.2.5.1B Activation or modification of IP-CAN for media by the network

Not applicable.

#### M.2.2.5.1C Deactivation of IP-CAN for media

Not applicable.

### M.2.2.5.2 Special requirements applying to forked responses

Not applicable.

### M.2.2.5.3 Unsuccessful situations

Not applicable.

## M.2.2.6 Emergency service

### M.2.2.6.1 General

When establishing an HRPD session to perform emergency registration, the UE shall follow the procedures defined in 3GPP2 X.S0060 [86B].

To determine whether the HRPD UE is attached to the home network or to the visited network, the UE shall compare the Carrier ID values obtained per 3GPP2 X.S0060 [86B]. If the Carrier ID of the network the UE is attached to does not match with the provisioned Carrier ID, then for the purpose of emergency calls in the IM CN subsystem the UE shall consider to be attached to a visited network.

NOTE: For 3GPP2-1X and 3GPP2-UMB, no IP-CAN specific support is provided in the current release. No carrier identification is provided for 3GPP2-1X or 3GPP2-UMB in the P-Access-Network-Info header field, and thus there is no IMS specific procedure for identifying that the UE is in the home network.

#### M.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### M.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

#### M.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### M.2.2.6.3 Current location discovery during an emergency call

Void.

---

## M.2A Usage of SDP

### M.2A.0 General

Not applicable.

### M.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

Not applicable.

### M.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

### M.2A.3 Emergency service

No additional procedures defined.

---

## M.3 Application usage of SIP

### M.3.1 Procedures at the UE

#### M.3.1.0 Void

#### M.3.1.0a IMS\_Registration\_handling policy

Not applicable.

#### M.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

### M.3.1.1 Cellular-Network-Info header field

Not applicable.

### M.3.1.2 Availability for calls

Not applicable.

### M.3.1.2A Availability for SMS

Void.

### M.3.1.3 Authorization header field

When using SIP digest or SIP digest without TLS, the UE need not include an Authorization header field on sending a REGISTER request, as defined in subclause 5.1.1.2.1.

**NOTE:** In case the Authorization header field is absent, the mechanism only supports that one public user identity is associated with only one private user identity. The public user identity is set so that it is possible to derive the private user identity from the public user identity by removing SIP URI scheme and the following parts of the SIP URI if present: port number, URI parameters, and To header field parameters. Therefore, the public user identity used for registration in this case cannot be shared across multiple UEs. Deployment scenarios that require public user identities to be shared across multiple UEs that don't include a private user identity in the initial REGISTER request can be supported as follows:

- Assign each sharing UE a unique public user identity to be used for registration,
- Assign the shared public user identities to the implicit registration set of the unique registering public user identities assigned to each sharing UE.

### M.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### M.3.1.5 3GPP PS data off

Not applicable.

### M.3.1.6 Transport mechanisms

No additional requirements are defined.

### M.3.1.7 RLOS

Not applicable.

## M.3.2 Procedures at the P-CSCF

### M.3.2.0 Registration and authentication

Void.

### M.3.2.1 Determining network to which the originating user is attached

For an HRPD UE, after the initial request for a dialog or standalone transaction or an unknown method is received the P-CSCF shall check the Carrier ID field received in the P-Access-Network-Info header field to determine from which network the request was originated.

NOTE: For 3GPP2-1X and 3GPP2-UMB, no IP-CAN specific support is provided in the current release. No carrier identification is provided for 3GPP2-1X or 3GPP2-UMB in the P-Access-Network-Info header field, and thus there is no IMS specific procedure for identifying that the UE is in the home network.

### M.3.2.2 Location information handling

Void

### M.3.2.3 Void

### M.3.2.4 Void

### M.3.2.5 Void

### M.3.2.6 Resource sharing

Not applicable.

### M.3.2.7 Priority sharing

Not applicable.

### M.3.2.8 RLOS

Not applicable.

## M.3.3 Procedures at the S-CSCF

### M.3.3.1 Notification of AS about registration status

The procedures described in subclause 5.4.1.7 apply with the additional procedures described in the present subclause:

- 1) in case the received REGISTER request contained a Timestamp header field, the S-CSCF shall insert a Timestamp header field with the value of the Timestamp header field from the received REGISTER request.

### M.3.3.2 RLOS

Not applicable.

---

## M.4 3GPP specific encoding for SIP header field extensions

### M.4.1 Void

---

## M.5 Use of circuit switched domain

When an emergency call is to be set up over the CS domain, the UE shall attempt it according to the procedures described in 3GPP2 C.S0005-D [85].

---

# Annex N (Normative): Functions to support overlap signalling

## N.1 Scope

This annex defines the procedures performed by network entities within the IM CN subsystem to support overlap signalling.

The support of overlap signalling within the IM CN subsystem is optional, and is depended on the network policy.

---

## N.2 Digit collection function

### N.2.1 General

The digit collection function is invoked if an entity requires additional digits for a decision where to route a INVITE request.

NOTE 1: The digit collection function is only applicable for the in-dialog method of overlap signalling. Further information about digit collection is provided in subclause 4.9.3.3.

The digit collection function may interact with a routing database, to reach this decision. The digit collection function shall be performed by an entity acting as a B2BUA. The digit collection function requires the ability to recognise incomplete numbers. The digit collection function may be implemented in different network nodes depending on the operator's deployment strategy (e.g. AS, IBCF).

NOTE 2: An HSS does not support the recognition of incomplete numbers. A routing database being queried by ENUM also does not support the recognition of incomplete numbers.

NOTE 3: A private routing database to support the recognition of incomplete numbers e.g. for transit calls or ported numbers can be used.

### N.2.2 Collection of digits

#### N.2.2.1 Initial INVITE request

Upon receiving an initial INVITE request carrying an SDP offer, the digit collection function shall:

- 1) if the request contains enough digits to forward the request, forward the request towards its destination;
- 2) if the digit collection function chooses to collect additional digits in INFO requests, in order to forward the request, and the sender of the INVITE request has indicated support of reliable responses, store the received digits and send a reliable 183 (Session Progress) provisional response in order to establish an early dialog with the sender of the INVITE request. The response shall not contain an SDP answer; or
- 3) if it is determined that the en-bloc will not be able to forward the request even if additional digits are received,, send a 404 (Not Found) response.

Upon receiving an initial INVITE request without an SDP offer, the digit collection function shall:

- 1) if the request contains enough digits to forward the request, forward the request towards its destination; or
- 2) send a 404 (Not Found) response.

NOTE 1: If the initial INVITE request does not contain an SDP offer, a reliable 18x provisional response generated by the en-bloc conversion function would have to contain an SDP offer. In this case digit collection needs to be performed by the originating SIP entity (e.g. MGCF).

When the digit collection function sends the reliable 183 (Session Progress) provisional response, in order to establish an early dialog with the sender of the INVITE request, the digit collection function shall start a digit collection timer. If the timer expires, the digit collection function shall terminate the call setup by sending a sending a 484 (Address Incomplete) response towards the sender of the INVITE request.

NOTE 2: The digit collection timer is similar to the protection timer used in PSTN/ISDN. The timer value range is between 5 and 15 seconds, and the default value is 10 seconds.

### N.2.2.2 Collection of additional digits

Upon receiving an INFO request carrying additional digits, and if an early dialog towards the destination of the initial INVITE request for the call does not exist, the digit collection function shall:

- 1) send a 200 (OK) response to the INFO request;
- 2) add the received digits to the previously stored digits for the call;
- 3) restart the digit collection timer; and
- 4) check if enough digits have been received in order to forward the initial INVITE request.

When enough digits for the call have been received in order to forward the initial INVITE request, the digit collection function shall add all stored digits to the request URI and forward the request towards its destination and stop the digit collection timer.

Upon receiving an INFO request carrying additional digits, and the initial INVITE request has been forwarded towards its destination, but an early dialog towards the destination of the initial INVITE request for the call does not exist, the digit collection function shall:

- 1) send a 200 (OK) response to the INFO request; and
- 2) add the received digits to the previously stored, but yet not forwarded, digits for the call;

When the digit collection function receives a provisional response from the destination of the initial INVITE request, and the digit collection function has received additional digits in INFO requests, the digit collection shall generate and send an INFO request towards the destination of the initial INVITE request. The Request-URI shall contain all digits which have been received and stored since the initial INVITE request was forwarded.

Upon receiving an INFO request carrying additional digits, and if an early dialog towards the destination of the initial INVITE request for the call does exist, the digit collection function shall forward the INFO request on the early dialog towards the destination of the initial SIP INVITE request.

Upon receiving an INFO request carrying additional digits, and if a 180 (Ringing) or a 200 (OK) response to the initial INVITE request for the call has been received, or the digit collection function has received some other indication that enough digits have been forwarded in order for the INVITE request to reach the terminating SIP user, the digit collection function shall, based on operator policy:

- 1) send a 200 (OK) response to the INFO request and not forward the INFO request; or
- 2) forward the INFO request on the early dialog towards the destination of the initial SIP INVITE request.

### N.2.2.3 Handling of 404 (Not Found) / 484 (Address Incomplete) responses

Upon receiving a 404/484 response to the initial INVITE request, the digit collection function shall acknowledge the response and shall start the digit collection timer. The digit collection function shall not forward the response towards the sender of the INVITE request.

NOTE: If the digit collection function has received a 404/484 response, it will send a new initial INVITE request when it has received additional digits as described above, in order to establish an early dialog towards the destination of the INVITE request. The digit collection timer will re-start if an INFO request with additional digits is received. At timer expiry, the digit collection function will terminate the call as described above

## N.2.3 Forwarding of SIP messages by the digit collection function

Apart from 404/484 responses to the initial INVITE request, and INFO requests carrying additional digits received after a 180 (Ringing) or a 200 (OK) response to the initial INVITE request has been received, the digit collection function shall forward all SIP messages. When forwarding SIP messages, the digit collection function shall modify the SIP messages to comply with SIP procedures on both call legs as specified below:

- 1) The digit collection function will receive a "tag" To header field parameter value from the receiver of the initial INVITE request, which is different from the "tag" To header field parameter value that the digit collection function inserted in the 183 (Session Progress) response that it sent when it received the initial INVITE request. The digit collection function shall modify the "tag" header field parameter value accordingly when forwarding mid-dialog SIP messages.
- 2) The digit collection function will return a Contact header field in the initial 183 (Session Progress) provisional response to the originating side, which contains a SIP-URI of the digit collection function. The contact information is used in the Request-URI of subsequent mid-dialog SIP requests sent by the originating side, until the digit collection function has received, and forwarded to the originating side, a 183 (Session Progress) provisional response from the destination of the INVITE request. If the Request-URI of the received mid-dialog SIP request contains the SIP-URI of the digit collection function, and the digit collection function forwards the request, the digit collection function shall modify the Request-URI before forwarding the SIP request.
- 3) The digit collection function will return the Record-Route header fields, which it received in the initial INVITE request, in the initial 183 (Session Progress) provisional response to the originating side. The information is used in the Route header fields of subsequent mid-dialog SIP requests sent by the originating side, until the digit collection function has received, and forwarded to the originating side, a 183 (Session Progress) provisional response from the destination of the INVITE request. If the Route header fields of the received mid-dialog SIP request are based on the Record-Route headers fields which the digit collection function returned in the initial 183 (Session Progress) provisional response, and the digit collection function forwards the request, the digit collection function shall modify the Route header fields before forwarding the SIP request.

---

## N.3 En-bloc conversion function

### N.3.1 General

The en-bloc conversion function may be performed in an entity acting as B2BUA. The en-bloc conversion function may be implemented in different network nodes depending on the operator's deployment strategy (e.g. AS, IBCF).

If the initial INVITE request is to be forwarded towards a network, or towards a network entity, that does not support overlap signalling, the en-bloc conversion function shall determine the end of address signalling.

The following methods can be used to determine the end of the address signalling:

- 1) the maximum number of digits used in a national numbering plan has been received;
- 2) number analysis, e.g. using a provisioned dial plan, is used to determine that the complete number of digits has been received; or
- 3) an inter digit timer expires, and the minimum number of digits required for routing the call have been received. The timer is started when the initial INVITE request is received, and re-started every time new digit(s) are received.

**NOTE:** The inter digit timer is similar to the protection timer used in PSTN/ISDN. The timer value range is between 5 and 15 seconds, and the default value is 10 seconds.

The procedures for collecting additional digits are described in subclauses N.3.2 and N.3.3. When end of address signalling has been determined, the en-bloc conversion function shall generate an INVITE request, add all digits to the request and forwards the request towards its destination.

## N.3.2 Multiple-INVITE method

Upon reception of an INVITE request, the en-bloc conversion function shall:

- 1) if an inter digit timer is running for a previously received INVITE request with the same Call-ID and From header, and
  - a) if the number of digits within that previous INVITE request is below the number of digits received in the new INVITE request (or as an equivalent test if the CSeqID of the previous INVITE request is below the CSeqID of the new INVITE request), stop the inter-digit timer for that previous INVITE request and send a 484 (Address Incomplete) response for it; and
  - b) if the number of digits with the previous INVITE request is above or equal to the number of digits received in the new INVITE request (or as an equivalent test if the CSeqID of the previous INVITE request is below the CSeqID of the new INVITE request), send a 484 (Address Incomplete) response for the new INVITE request; and
- 2) if the en-bloc conversion function determines that the number received in the INVITE request is complete, forward the INVITE request; and
- 3) if the en-bloc conversion function determines that it will not be able to forward the request even if additional digits are received, send a 404 (Not Found) response; and
- 4) if the en-bloc conversion function chooses to collect additional digits, store the INVITE request and start an inter-digit timer to wait for possible INVITE requests with the same Call ID and From header.

When the inter-digit timer expires the en-bloc conversion function shall:

- 1) if it determines that the number received in the stored INVITE request is incomplete (e. g. by number analysis), terminate the call setup by sending a 484 (Address Incomplete) response towards the sender of the INVITE request; and
- 2) if it does not determine that the number received in the last INVITE request is incomplete, forward the corresponding stored INVITE request to the next hop.

After forwarding an INVITE request, the en-bloc conversion function shall apply SIP proxy procedures for all subsequent SIP messages within the corresponding dialogue, unless other functionality not related to en-bloc conversion allocated in the same physical node requires a different behaviour.

## N.3.3 In-dialog method

Upon receiving an initial INVITE request carrying an SDP offer, the en-bloc conversion function shall:

- 1) if it determines that the request contains a complete number, forward the request towards its destination;
- 2) if the en-bloc conversion function chooses to collect additional digits in INFO requests before forwarding the request, and the sender of the INVITE request has indicated support of reliable responses, store the received digits, send a reliable 183 (Session Progress) provisional response without an SDP answer in order to establish an early dialog with the sender of the INVITE request, and start an inter digit timer; or
- 3) if the en-bloc conversion function determines that it will not be able to forward the request even if additional digits are received, send a 404 (Not Found) response.

Upon receiving an initial INVITE request without an SDP offer, the en-bloc conversion function shall:

- 1) if it is determined that the request contains a complete number, forward the request towards its destination; or
- 2) send a 404 (Not Found) response.

NOTE: If the initial INVITE request does not contain an SDP offer, a reliable 18x provisional response generated by the en-bloc conversion function would have to contain an SDP offer. The en-bloc conversion function for the in-dialog method specified here does not support en-bloc conversion for calls with an initial INVITE request that does not contain an SDP offer in the present release. However, en-bloc conversion for an initial INVITE request that does not contain an SDP offer can be performed by the originating SIP entity (e.g. MGCF).

Upon receiving an INFO request carrying additional digits, and an early dialog towards the destination of the initial SIP INVITE request for the call has not been created, the en-bloc conversion function shall:

- 1) send a 200 (OK) response to the INFO request;
- 2) add the received digits to the previously stored digits for the call;
- 3) re-start the inter digit timer; and
- 4) check if it can determine that a complete number for the call has been received.

When the en-bloc conversion function determines that a complete number for the call has been received, it shall add all stored digits to the initial INVITE request and forward the request towards its destination and stop the inter digit timer.

When the inter-digit timer expires the en-bloc conversion function shall

- 1) if it determines that the number so far is incomplete (e. g. by number analysis), terminate the call setup by sending a 484 (Address Incomplete) response towards the sender of the INVITE request; or
- 2) if it does not determine that the number received in the last INVITE request is incomplete, forward the INVITE request to the next hop, including all received digits.

Upon receiving an INFO request carrying additional digits, if the en-bloc conversion function has forwarded the initial INVITE request towards its destination, the en-bloc conversion function shall send a 200 (OK) response to the INFO request and not forward the INFO request.

Apart from INFO requests carrying additional digits received after the initial INVITE request has been forwarded, the en-bloc conversion function shall forward all SIP messages.

The en bloc conversion function will receive a "tag" To header field parameter value from the receiver of the initial INVITE request, which is different from the "tag" To header field parameter value that the digit collection function inserted in the 183 (Session Progress) response that it sent when it received the initial INVITE request. The digit collection function shall modify the "tag" To header field parameter value accordingly when forwarding in-dialog SIP messages.

---

# Annex O (normative): IP-Connectivity Access Network specific concepts when using the EPC via cdma2000<sup>®</sup> HRPD to access IM CN subsystem

## O.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is the Evolved Packet Core (EPC) via a cdma2000<sup>®</sup> HRPD access network.

---

## O.2 IP-CAN aspects when connected to the IM CN subsystem

### O.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the EPC and cdma2000<sup>®</sup> HRPD access network as specified by 3GPP2 X.P0057 [86C] to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause. Requirements for the P-GW in support of this communication are specified in 3GPP TS 29.061 [11] and 3GPP TS 29.212 [13B].

Requirements for the use of the EPC via packet cdma2000<sup>®</sup> HRPD as an IP-CAN are specified in 3GPP2 X.P0057 [86C].

### O.2.2 Procedures at the UE

#### O.2.2.1 IP-CAN bearer context activation and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall:

- a) establish a connection with the IP-CAN via the cdma2000<sup>®</sup> HRPD wireless IP network specified in 3GPP2 X.P0057 [86C]. Upon establishing a connection with the cdma2000<sup>®</sup> eHRPD wireless IP network, the UE can have an IPv4 address only, an IPv6 address only, or both IPv4 and IPv6 addresses simultaneously;
- b) ensure that a IP-CAN bearer context used for SIP signalling is available, according to the APN and P-GW selection criteria described in 3GPP TS 23.402 [7E]. This IP-CAN bearer context shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration; and

NOTE 1: Any IP-CAN bearer can carry both IM CN subsystem signalling and media if the media does not need to be authorized by Policy and Charging control mechanisms as defined in 3GPP TS 29.212 [13B], and the media stream is not mandated by the P-CSCF to be carried in a separate IP-CAN bearer.

NOTE 2: IP-CAN PDN connection and bearer management procedures are specified in 3GPP2 X.P0057 [86C].

- c) acquire a P-CSCF address(es).

The methods for P-CSCF discovery are:

- I. Use DHCP mechanism

- II Retrieve the list of P-CSCF address(es) stored in the IMC
- III Obtain the list of P-CSCF address(es) from the IMS management object
- IV. Transfer P-CSCF address(es) within the IP-CAN bearer context activation procedure.

The UE shall indicate the request for a P-CSCF address to the network within the Protocol Configuration Options information element of the during PDN connectivity establishment as specified in 3GPP2 X.P0057 [86C].

If the network provides the UE with a list of P-CSCF IPv4 or IPv6 addresses, the UE shall assume that the list is prioritised with the first address within the Protocol Configuration Options information element as the P-CSCF address with the highest priority.

The UE can freely select method I, II, III, or IV for P-CSCF discovery. If DHCP is used, the following procedures apply:

Upon establishing an IP-CAN bearer, the UE may use the Dynamic Host Configuration Protocol (DHCP) specified in RFC 2131 [40A] or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) specified in RFC 3315 [40] to discover the P-CSCF.

Prior to accessing the DHCP server, the UE will have obtained an IP address via means other than DHCP and DHCPv6.

If the UE uses DHCP for P-CSCF discovery and the UE is unaware of the address of the DHCP server, the UE shall send the DHCPINFORM using the limited broadcast IP address (i.e., 255.255.255.255) and UDP port 67. If the UE knows the IP address of the DHCP server, the UE shall send the DHCPINFORM to the DHCP server's unicast IP address and UDP port 67. The DHCP server shall send the DHCPACK on the IP address specified in the Client IP Address field of the DHCPINFORM. The DHCP server may include, in the DHCPACK, the SIP Server DHCP Option specified in RFC 3361 [35A], which carries either a list of IPv4 address(es) of the P-CSCF(s) or a list of DNS fully qualified domain name(s) that can be mapped to one or more P-CSCF(s). If the UE uses DHCPv6 for P-CSCF discovery and the UE is unaware of the address of the DHCP Server, the UE shall send an Information Request using the IPv6 multicast address FF02::1:2 and the UDP port 547. If the UE knows the IP address of the DHCPv6 server, the UE shall send the Information Request message to the DHCPv6 server's IP address and UDP port 547. In the Information Request, the UE may request either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option specified in RFC 3319 [41]. The DHCP server shall send the Reply to the IP address specified in the Information Request. The DHCP server may include in the Reply either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option, as requested by the UE.

In case several P-CSCF's IP addresses or domain names are provided to the UE, the UE shall perform P-CSCF selection according to RFC 3361 [35A] or RFC 3319 [41]. The UE shall perform the procedure for the resolution of domain name according to RFC 3263 [27A].

### O.2.2.1A Modification of an IP-CAN bearer context used for SIP signalling

The UE shall not modify the IP-CAN bearer from being used exclusively for SIP signalling to a general purpose IP-CAN bearer and vice versa.

After the establishment of a SIP bearer context used for SIP signalling, the UE shall not indicate the request for a P-CSCF address to the network when requesting an IP-CAN bearer modification for that APN. The UE shall ignore P-CSCF address(es) if received from the network as part of the bearer modification procedure.

### O.2.2.1B Re-establishment of the IP-CAN bearer context for SIP signalling

If the IP-CAN bearer context for SIP signalling is lost and cannot be re-established:

- a. if the SIP signalling was carried over a dedicated IP-CAN bearer, the UE shall release all resources established as a result of SIP signalling by either:
  - requesting an IP-CAN bearer modification if there are IP-CAN bearers to this PDN that are not related SIP sessions; or

- initiating disconnection of the PDN connection if all the bearers to this PDN are related to SIP sessions.

NOTE: If the SIP signalling was carried over the default IP-CAN bearer, all the resources established as a result of SIP signalling are released.

### O.2.2.1 CP-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure performs one of the following procedures:

- A if the UE used method II for P-CSCF discovery and if the UE receives one or more P-CSCF address(es) in an VSNCP Configure-Request message and the one or more P-CSCF address(es) do not include the address of the currently used P-CSCF, then the UE shall acquire a different P-CSCF address from the one or more P-CSCF address(es) in the VSNCP Configure-Request message. The UE shall assume that the more than one P-CSCF address are prioritised with the first P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address with the highest priority;
- B if the UE uses RFC 6223 [143] as part of P-CSCF restoration procedures, and if the P-CSCF fails to respond to a keep-alive request, then the UE shall acquire a different P-CSCF address using one of the methods I, II and III for P-CSCF discovery described in the subclause O.2.2.1.

When a different P-CSCF address is acquired the UE shall perform an initial registration as specified in subclause 5.1.

### O.2.2.2 Session management procedures

The existing procedures for session management as described in 3GPP2 X.P0057 [86C] shall apply while the UE is connected to the IM CN subsystem.

### O.2.2.3 Mobility management procedures

The existing procedures for mobility management as described in 3GPP2 X.P0057 [86C] shall apply while the UE is connected to the IM CN subsystem.

### O.2.2.4 Cell selection and lack of coverage

The existing mechanisms and criteria for cell selection as described in 3GPP2 C.S0014-C [86D] shall apply while the UE is connected to the IM CN subsystem.

### O.2.2.5 IP-CAN bearer contexts for media

#### O.2.2.5.1 General requirements

NOTE 1: The UE cannot control whether media streams belonging to different SIP sessions are established on the same IP-CAN bearer context or not. During establishment of a session, the UE establishes data stream(s) for media related to the session. Such data stream(s) can result in activation of additional IP-CAN bearer context(s). Either the UE or the network can request for resource allocations for media, but the establishment and modification of the IP-CAN bearer is controlled by the network as described in 3GPP2 X.P0057 [86C].

NOTE 2: When the UE wishes to allocate bandwidth for RTP and RTCP, the rules as outlined in 3GPP TS 29.213 [13C] apply. Application of QoS to when using an EPC IP-CAN with cdma2000<sup>®</sup> HRPD is described in 3GPP2 X.P0057 [86C].

#### O.2.2.5.1A Activation or modification of IP-CAN bearer contexts for media by the UE

No additional clarifications are needed for the use of the EPC via cdma2000<sup>®</sup> HRPD as an IP-CAN.

### O.2.2.5.1B Activation or modification of IP-CAN bearer contexts for media by the network

If the UE receives an activation request from the network for an IP-CAN bearer context which is associated with the IP-CAN bearer context used for signalling, the UE shall, based on the information contained in the Traffic Flow Template provided by the network, correlate the media IP-CAN bearer context with a currently ongoing SIP session establishment or SIP session modification.

If the UE receives a modification request from the network for an IP-CAN bearer context that is used for one or more media streams in an ongoing SIP session, the UE shall modify the related IP-CAN bearer context in accordance with the request received from the network.

### O.2.2.5.1C Deactivation of of IP-CAN bearer contexts for media

Not applicable

### O.2.2.5.2 Special requirements applying to forked responses

NOTE 1: The procedures in this subclause only apply when the UE requests activation and modification of media bearers. In the case where the network activates and modifies the media bearers the network takes care of the handling of media bearers in the case of forking.

Since the UE does not know that forking has occurred until a second, provisional response arrives, the UE requests resource allocation as required by the initial response received. If a subsequent provisional response is received, different alternative actions may be performed depending on the requirements in the SDP answer:

- 1) the bearer requirements of the subsequent SDP can be accommodated by the existing resources requested. The UE performs no further resource requests.
- 2) the subsequent SDP introduces different QoS requirements or additional IP flows. The UE requests further resource allocation according to subclause O.2.2.5.1.
- 3) the subsequent SDP introduces one or more additional IP flows. The UE requests further resource allocation according to subclause O.2.2.5.1.

NOTE 2: When several forked responses are received, the resources requested by the UE are the "logical OR" of the resources indicated in the multiple responses to avoid allocation of unnecessary resources. The UE does not request more resources than proposed in the original INVITE request.

When a final answer is received for one of the early dialogs, the UE proceeds to set up the SIP session. The UE shall release all the unneeded IP-CAN resources. Therefore, upon the reception of the first final 200 (OK) response for the INVITE request (in addition to the procedures defined in RFC 3261 [26] subclause 13.2.2.4), the UE shall:

- 1) in case resources were established or modified as a consequence of the INVITE request and forked provisional responses that are not related to the accepted 200 (OK) response, send release request to release the unneeded resources.

### O.2.2.5.3 Unsuccessful situations

Not applicable.

## O.2.2.6 Emergency service

### O.2.2.6.1 General

Emergency services is not supported when the IP-CAN is the EPC via a cdma2000® HRPD access network.

#### O.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### O.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

#### O.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### O.2.2.6.3 Current location discovery during an emergency call

Void.

---

## O.2A Usage of SDP

### O.2A.0 General

Not applicable.

### O.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN bearer context for media by the network

If, due to the activation of an IP-CAN bearer context from the network the related SDP media description needs to be changed the UE shall update the related SDP information by sending a new SDP offer within a SIP request, which is sent over the existing SIP dialog,

If the UE receives a modification request from the network for an IP-CAN bearer context that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) if, due to the modification of the IP-CAN bearer context, the related SDP media description need to be changed, update the related SDP information by sending a new SDP offer within a SIP request, that is sent over the existing SIP dialog, and respond to the IP-CAN bearer context modification request.

NOTE: The UE can decide to indicate additional media streams as well as additional or different codecs in the SDP offer than those used in the already ongoing session.

### O.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

If the UE receives an SDP offer where the SDP offer includes all media streams for which the originating side indicated its local preconditions as met, if the precondition mechanism is supported by the terminating UE and the IP-CAN performs network-initiated resource reservation for the terminating UE and the available resources are not sufficient for the received offer the terminating UE shall indicate its local preconditions and provide the SDP answer to the originating side without waiting for resource reservation.

NOTE: If the resource reservation is controlled by the network, the resource reservation request is initiated by the network after the P-CSCF has authorised the respective IP flows and provided the QoS requirements over the Rx interface to the PCRF as described in 3GPP TS 29.214 [13D].

### O.2A.3 Emergency service

No additional procedures defined.

---

## O.3 Application usage of SIP

### O.3.1 Procedures at the UE

#### O.3.1.0 Void

#### O.3.1.0a IMS\_Registration\_handling policy

Not applicable.

#### O.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

#### O.3.1.1A Cellular-Network-Info header field

Not applicable.

#### O.3.1.2 Availability for calls

Not applicable.

#### O.3.1.2A Availability for SMS

Void.

#### O.3.1.3 Authorization header field

When using SIP digest or SIP digest without TLS, the UE need not include an Authorization header field on sending a REGISTER request, as defined in subclause 5.1.1.2.1.

**NOTE:** In case the Authorization header field is absent, the mechanism only supports that one public user identity is associated with only one private user identity. The public user identity is set so that it is possible to derive the private user identity from the public user identity by removing SIP URI scheme and the following parts of the SIP URI if present: port number, URI parameters, and To header field parameters. Therefore, the public user identity used for registration in this case cannot be shared across multiple UEs. Deployment scenarios that require public user identities to be shared across multiple UEs that don't include an private user identity in the initial REGISTER request can be supported as follows:

- Assign each sharing UE a unique public user identity to be used for registration,
- Assign the shared public user identities to the implicit registration set of the unique registering public user identities assigned to each sharing UE.

#### O.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

#### O.3.1.5 3GPP PS data off

Not applicable.

### O.3.1.6 Transport mechanisms

No additional requirements are defined.

### O.3.1.7 RLOS

Not applicable.

## O.3.2 Procedures at the P-CSCF

### O.3.2.0 Registration and authentication

Void.

### O.3.2.1 Determining network to which the originating user is attached

The P-CSCF handling is as defined in subclause M.3.2.

**NOTE:** Emergency call support for the EPC IP-CAN is not specified in this release. A common P-Access-Network-Info header field value is used for both cdma2000<sup>®</sup> HRPD based IP-CANs (i.e. HRPD access specified by 3GPP2 X.S0011-E [127], and HRPD access as specified by 3GPP2 X.P0057 [86C]). The result of this is that in both cases the handling in the P-CSCF will be identical. If an operator deploys an IM CN subsystem with both cdma2000<sup>®</sup> HRPD based IP-CANs, the P-CSCF has no means of distinguishing one from the other. The emergency call handling for the EPC IP-CAN using cdma2000<sup>®</sup> HRPD access as specified by 3GPP2 X.P0057 [86C] is out of scope for this release of this specification, and therefore all identified emergency calls with a P-Access-Network-Info header field value of "3GPP2-1X-HRPD" will be handled with a 380 (Alternative Service) response when HRPD IP-CAN emergency support is not active.

### O.3.2.2 Location information handling

Void.

### O.3.2.3 Void

### O.3.2.4 Void

### O.3.2.5 Void

### O.3.2.6 Resource sharing

If the P-CSCF supports resource sharing, PCC is supported for this access technology and if according to local policy, the P-CSCF shall apply the procedures in subclause L.3.2.6.

### O.3.2.7 Priority sharing

If the P-CSCF supports priority sharing, PCC is supported for this access technology and if according to operator policy, the P-CSCF shall apply the procedures in subclause L.3.2.7.

### O.3.2.8 RLOS

Not applicable.

## O.3.3 Procedures at the S-CSCF

### O.3.3.1 Notification of AS about registration status

The S-CSCF handling is as defined in subclause M.3.3.1.

### O.3.3.2 RLOS

Not applicable.

---

## O.4 3GPP specific encoding for SIP header field extensions

### O.4.1 Void

---

## O.5 Use of circuit-switched domain

There is no CS domain in this access technology.

Annex P (informative):  
Void

---

# Annex Q (normative): IP-Connectivity Access Network specific concepts when using the cdma2000<sup>®</sup> 1x Femtocell Network to access IM CN subsystem

## Q.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is an IP network as incorporated into the cdma2000<sup>®</sup> 1x femtocell network subsystem [86E].

---

## Q.2 cdma2000<sup>®</sup> 1x Femtocell Network aspects when connected to the IM CN subsystem

### Q.2.1 Introduction

In the cdma2000<sup>®</sup> 1x femtocell network subsystem, the cdma2000<sup>®</sup> 1x Mobile Station (MS) accesses the IM CN subsystem by utilising the services provided by the cdma2000<sup>®</sup> 1x Femtocell Access Point (FAP) [86E].

NOTE: Protocol between the cdma2000<sup>®</sup> 1x MS and the cdma2000<sup>®</sup> 1x FAP is out of scope of this document.

The cdma2000<sup>®</sup> 1x FAP 3GPP2 X.P0059-200 [86E] acts as a UE toward the IM CN subsystem.

From the perspective of the FAP, it is assumed that one or more IP-CAN bearer(s) are provided, in the form of connection(s) managed by the layer 2.

### Q.2.2 Procedures at the UE

#### Q.2.2.1 Activation and P-CSCF discovery

Unless a static IP address is allocated to the cdma2000<sup>®</sup> 1x FAP, prior to communication with the IM CN subsystem, the cdma2000<sup>®</sup> 1x FAP shall perform a Network Attachment procedure depending on the used cdma2000<sup>®</sup> 1x FAP access type. When using a cdma2000<sup>®</sup> 1x FAP access, both IPv4 and IPv6 may be used to access the IM CN subsystem. The cdma2000<sup>®</sup> 1x FAP may request a DNS Server IPv4 address(es) via RFC 2132 [20F] or a DNS Server IPv6 address(es) via RFC 3315 [40].

When using IPv4, the cdma2000<sup>®</sup> 1x FAP may acquire a P-CSCF address(es) by using the DHCP (see RFC 2132 [20F]), the DHCPv4 options for SIP servers (see RFC 3361 [35A]), and RFC 3263 [27A].

In case the DHCP server provides several P-CSCF addresses or FQDNs to the cdma2000<sup>®</sup> 1x FAP, the cdma2000<sup>®</sup> 1x FAP shall select the P-CSCF address or FQDN as indicated in RFC 3361 [35A]. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the cdma2000<sup>®</sup> 1x FAP is implementation specific.

When using IPv6, the cdma2000<sup>®</sup> 1x FAP may acquire a P-CSCF address(es) by using the DHCPv6 (see RFC 3315 [40] and RFC 3646 [56C]), the DHCPv6 options for SIP servers (see RFC 3319 [41]), and RFC 3263 [27H].

In case the DHCP server provides several P-CSCF addresses or FQDNs to the cdma2000<sup>®</sup> 1x FAP, the cdma2000<sup>®</sup> 1x FAP shall select the P-CSCF address or FQDN as indicated in RFC 3319 [41]. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the cdma2000<sup>®</sup> 1x FAP is implementation specific.

### Q.2.2.1A Modification of IP-CAN used for SIP signalling

Not applicable.

### Q.2.2.1B Re-establishment of IP-CAN used for SIP signalling

Not applicable.

### Q.2.2.2 Void

### Q.2.2.3 Void

### Q.2.2.4 Void

### Q.2.2.5 Handling of the IP-CAN for media

#### Q.2.2.5.1 General requirements

The cdma2000<sup>®</sup> 1x FAP uses the bearer used for signalling also for transmission of media.

#### Q.2.2.5.1A Activation or modification of IP-CAN for media by the UE

Not applicable.

#### Q.2.2.5.1B Activation or modification of IP-CAN for media by the network

Not applicable.

#### Q.2.2.5.1C Deactivation of IP-CAN for media

Not applicable

#### Q.2.2.5.2 Special requirements applying to forked responses

Not applicable.

#### Q.2.2.5.3 Unsuccessful situations

Not applicable.

### Q.2.2.6 Emergency service

#### Q.2.2.6.1 General

Emergency calls are perceived as regular calls from the perspective of the IM CN subsystem. Entities outside the IM CN subsystem identify and route such calls to PSAP.

#### Q.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### Q.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

#### Q.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### Q.2.2.6.3 Current location discovery during an emergency call

Void.

---

## Q.2A Usage of SDP

### Q.2A.0 General

Not applicable.

#### Q.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

Not applicable.

#### Q.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

#### Q.2A.3 Emergency service

No additional procedures defined.

---

## Q.3 Application usage of SIP

### Q.3.1 Procedures at the UE

#### Q.3.1.0 Void

#### Q.3.1.0a IMS\_Registration\_handling policy

Not applicable.

#### Q.3.1.1 P-Access-Network-Info header field

The cdma2000<sup>®</sup> 1x FAP shall include the P-Access-Network-Info header field where indicated in subclause 5.1.

#### Q.3.1.1A Cellular-Network-Info header field

Not applicable.

### Q.3.1.2 Availability for calls

Not applicable.

### Q.3.1.2A Availability for SMS

Void.

### Q.3.1.3 Authorization header field

Void.

### Q.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### Q.3.1.5 3GPP PS data off

Not applicable.

### Q.3.1.6 Transport mechanisms

No additional requirements are defined.

### Q.3.1.7 RLOS

Not applicable.

## Q.3.2 Procedures at the P-CSCF

### Q.3.2.0 Registration and authentication

Void.

### Q.3.2.1 Determining network to which the originating user is attached

If access-type field in the P-Access-Network-Info header field indicated 3GPP2-1X-Femto access the P-CSCF shall assume that an initial request for a dialog or standalone transaction or an unknown method destined for a PSAP is initiated in the same country.

### Q.3.2.2 Location information handling

Not applicable

Q.3.2.3 Void

Q.3.2.4 Void

Q.3.2.5 Void

Q.3.2.6 Resource sharing

# Annex R (normative): IP-Connectivity Access Network specific concepts when using the EPC via WLAN to access IM CN subsystem

## R.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IM CN subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is the Evolved Packet Core (EPC) via Wireless Local Access Network (WLAN).

---

## R.2 IP-CAN aspects when connected to the IM CN subsystem

### R.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the EPC and the WLAN to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause.

### R.2.2 Procedures at the UE

#### R.2.2.1 Establishment of IP-CAN bearer and P-CSCF discovery

Prior to communication with the IM CN subsystem:

NOTE 1: The UE performs access network discovery and selection procedures as specified in 3GPP TS 24.302 [8U] and executes access authentication signalling for access to the EPC between the UE and 3GPP AAA server, if applicable, as described in 3GPP TS 24.302 [8U] prior to perform the procedure to obtain a local IP address;

- a) the UE establishes an IP-CAN bearer for SIP signalling as follows:
  - 1) if the UE attaches to the EPC via S2b using untrusted WLAN IP access:
    - A) the UE shall obtain a local IP address using the WLAN IP access;
    - B) if the UE does not support procedures for access to the EPC via restrictive non-3GPP access network or unless the UE determines that the WLAN used is a restrictive non-3GPP access network, then the UE shall establish an IKEv2 security association and an IPsec ESP security association with ePDG as described in 3GPP TS 24.302 [8U]. If the UE supports the Fixed Access Broadband interworking, the UE shall apply the establishment of tunnel specified in 3GPP TS 24.139 [8X];

NOTE 2: UE can determine that the WLAN used is a restrictive non-3GPP access network if no IKEv2 response is received for the IKEv2 IKE\_SA\_INIT request, or using means out of scope of this specification.

- C) if the UE supports procedures for access to the EPC via restrictive non-3GPP access network, and if the UE determines that the WLAN used is a restrictive non-3GPP access network, then the UE may perform procedures for access to the EPC via restrictive non-3GPP access network as described in 3GPP TS 24.302 [8U], and may establish an IKEv2 security association and an IPsec ESP security association with ePDG via the firewall traversal tunnel;

- D) the IKEv2 security association and the IPsec ESP security association (tunnel) shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration; and
- E) the UE may carry both signalling and media on an IPsec ESP security association;
- 2) if the UE attaches to the EPC via S2c using the WLAN IP access:
- A) the UE shall obtain a local IP address;
- B) the UE shall establish an IKEv2 security association and an IPsec ESP security association as described in 3GPP TS 24.302 [8U] and 3GPP TS 24.303 [8V]. If the UE supports the Fixed Access Broadband interworking, the UE shall apply the establishment of tunnel specified in 3GPP TS 24.139 [8X];
- C) the IKEv2 security association and the IPsec ESP security association (tunnel) shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration;and
- D) the UE may carry both signalling and media on an IPsec ESP security association.
- 3) if the UE attaches to the EPC via S2a using a trusted WLAN IP access:
- A) the IPv4 address and/or IPv6 prefix is allocated as specified in 3GPP TS 24.302 [8U]; and
- B) the UE IP address shall remain valid throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration;

The UE can determine trust relationship of a non-3GPP IP access network as specified in 3GPP TS 24.302 [8U]; and

- b) the UE shall acquire a P-CSCF address(es).

The methods for P-CSCF discovery are:

- I. Use DHCP mechanism
- II. Use DNS

When using IPv4, the UE may request a DNS Server IPv4 address(es) via RFC 2132 [20F]. When using IPv6, the UE may request a DNS Server IPv6 address(es) via RFC 3315 [40] and RFC 3646 [56C].

- III. Obtain the list of P-CSCF address(es) from the IMS management object

- IV. Obtain P-CSCF address(es) using signalling for access to the EPC via WLAN.

If the UE attaches to the EPC via S2b using untrusted WLAN IP access, the UE shall request P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both using the P\_CSCF\_IP4\_ADDRESS attribute, the P\_CSCF\_IP6\_ADDRESS attribute or both in the CFG\_REQUEST configuration payload as described in 3GPP TS 24.302 [8U]. The network can provide the UE with the P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both using the P\_CSCF\_IP4\_ADDRESS attribute, the P\_CSCF\_IP6\_ADDRESS attribute or both in the CFG\_REPLY configuration payload as described in 3GPP TS 24.302 [8U]. If the UE receives multiple P-CSCF IPv4 or IPv6 addresses, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the CFG\_REPLY configuration payload as the P-CSCF address having the highest preference and the last P-CSCF address within the CFG\_REPLY configuration payload as the P-CSCF address having the lowest preference.

If the UE attaches to the EPC via S2a using trusted WLAN IP access using single-connection mode, the UE shall indicate request for P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both within the PROTOCOL\_CONFIGURATION\_OPTIONS item of the message with SCM\_REQUEST message type as described in 3GPP TS 24.302 [8U]. The network can provide the UE with the P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both within the PROTOCOL\_CONFIGURATION\_OPTIONS item of the message with SCM\_RESPONSE message type as described in 3GPP TS 24.302 [8U]. If the UE receives multiple P-CSCF IPv4 or IPv6 addresses, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the PROTOCOL\_CONFIGURATION\_OPTIONS item as the P-CSCF address having the highest preference and the last P-CSCF address within the PROTOCOL\_CONFIGURATION\_OPTIONS item as the P-CSCF address having the lowest preference.

If the UE attaches to the EPC via S2a using trusted WLAN IP access using multi-connection mode, the UE shall indicate request for P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both within the Protocol Configuration Options information element of the PDN CONNECTIVITY REQUEST message as described in 3GPP TS 24.244 [8ZB]. The network can provide the UE with the P-CSCF IPv4 address(es), P-CSCF IPv6 address(es) or both within the Protocol Configuration Options information element of the PDN CONNECTIVITY ACCEPT message as described in 3GPP TS 24.244 [8ZB]. If the UE receives multiple P-CSCF IPv4 or IPv6 addresses, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the highest preference and the last P-CSCF address within the Protocol Configuration Options information element as the P-CSCF address having the lowest preference.

The UE shall use method III to select a P-CSCF, if a P-CSCF is to be discovered in the home network and the WLAN, to which the UE is attached, is connected to a visited network.

The UE can freely select method I, II, III or IV for P-CSCF discovery if:

- the UE is in the home network; or
- the WLAN, to which the UE is attached, is connected to a visited network and the P-CSCF is to be discovered in the visited network.

If DHCP is used, the following procedures apply:

Upon establishing an IP-CAN, the UE may use the Dynamic Host Configuration Protocol (DHCP) specified in RFC 2131 [40A] or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) specified in RFC 3315 [40] to discover the P-CSCF.

Prior to accessing the DHCP server, the UE will have obtained an IP address via means other than DHCP and DHCPv6.

If the UE uses DHCP for P-CSCF discovery and the UE is unaware of the address of the DHCP server, the UE sends the DHCPINFORM using the limited broadcast IP address (i.e., 255.255.255.255) and UDP port 67. If the UE knows the IP address of the DHCP server, the UE shall send the DHCPINFORM to the DHCP server's unicast IP address and UDP port 67. The DHCP server sends the DHCPACK on the IP address specified in the Client IP Address field of the DHCPINFORM. The DHCP server can include, in the DHCPACK, the SIP Server DHCP Option specified in RFC 3361 [35A], which carries either a list of IPv4 address(es) of the P-CSCF(s) or a list of DNS fully qualified domain name(s) that can be mapped to one or more P-CSCF(s). If the UE uses DHCPv6 for P-CSCF discovery and the UE is unaware of the address of the DHCP Server, the UE shall send an Information Request using the IPv6 multicast address FF02::1:2 and the UDP port 547. If the UE knows the IP address of the DHCPv6 server, the UE shall send the Information Request message to the DHCPv6 server's IP address and UDP port 547. In the Information Request, the UE can request either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option specified in RFC 3319 [41]. The DHCP server sends the Reply to the IP address specified in the Information Request. The DHCP server can include in the Reply either one or both the SIP Servers Domain Name List option and the SIP Servers IPv6 Address List option, as requested by the UE.

In case several P-CSCF's IP addresses or domain names are provided to the UE, the UE shall perform P-CSCF selection according to RFC 3361 [35A] or RFC 3319 [41]. The UE shall perform the procedure for the resolution of domain name according to RFC 3263 [27A]. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the UE is implementation specific.

When:

- the UE obtains an IP-CAN bearer for SIP signalling by performing handover of the connection from another IP-CAN;
- IP address of the UE is not changed during the handover; and
- the UE already communicates with the IM CN subsystem via the connection with the other IP-CAN, e.g. the UE determines that its contact with host portion set to the UE IP address (or FQDN of the UE) associated with the connection with the other IP-CAN has been bound to a public user identity;

the UE shall continue using the P-CSCF address(es) acquired in the other IP-CAN.

The UE may support the policy on when a UE roaming in a VPLMN is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS as specified in subclause L.2.1.1. If the UE roams in the EPS IP-CAN, has a session and the policy indicates "roaming in a VPLMN and having an ongoing session, is not allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS", the UE shall not handover the PDN connection providing access to IMS from EPS to EPC via WLAN.

If the UE roams in the EPS IP-CAN, has a session and the policy indicates "roaming in a VPLMN and having an ongoing session, is allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS", the UE shall, if not prevented by other rules or policies, handover the PDN connection providing access to IMS from EPS to EPC via WLAN.

If the UE roams in the EPS IP-CAN and the policy indicates "roaming in a VPLMN is not allowed to transfer the PDN connection providing access to IMS between EPC via WLAN and EPS, irrespective of if the UE is in a session or not", the UE shall not handover the PDN connection providing access to IMS from EPS to EPC via WLAN. The UE can re-establish a new PDN connection to another IP-CAN type in idle mode, e.g. due to UE domain preference.

### R.2.2.1A Modification of an IP-CAN used for SIP signalling

Not applicable.

### R.2.2.1B Re-establishment of the IP-CAN used for SIP signalling

If the UE registered a public user identity with an IP address allocated for the APN of the IP-CAN bearer for SIP signalling, the IP-CAN bearer for SIP signalling is deactivated as result of signalling from the network, and:

- i) the signalling from the network results in requiring the UE to initiate activation of the IP-CAN bearer for SIP signalling; or
- ii) the UE needs to continue having a public user identity registered with an IP address allocated for the APN;

and the UE is allowed to activate the IP-CAN bearer for SIP signalling, the UE shall:

- A) if the non-access stratum is performing activation of the IP-CAN bearer for SIP signalling for the APN triggered as result of the signalling from the network, wait until the activation of the IP-CAN bearer for SIP signalling for the APN finishes;
- B) if the non-access stratum is not performing activation of the IP-CAN bearer for SIP signalling for the APN, perform the procedures in subclause R.2.2.1, bullet a); and
- C) if the IP-CAN bearer for SIP signalling is available:
  - perform the procedures in subclause R.2.2.1, bullet b); and
  - if a P-CSCF address was acquired, perform a new initial registration according to subclause 5.1.1.2.

### R.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure performs one of the following procedures:

- A) if the UE used method IV for P-CSCF discovery, the UE has previously sent the "P-CSCF Re-selection support" PCO indicator (in trusted non-3GPP access network) or the P-CSCF\_RESELECTION\_SUPPORT IKEv2 attribute (in untrusted non-3GPP access network) during the PDN connection establishment, and the UE receives one or more P-CSCF address(es) during the TWAG initiated PDN connectivity modification procedure (in trusted non-3GPP access network) or the ePDG initiated modification (in untrusted non-3GPP access network), then the UE shall acquire a P-CSCF address from the one or more P-CSCF address(es). If more than one P-CSCF addresses of the same IP address type are included, then the UE shall assume that the more than one P-CSCF addresses of the same IP address type are prioritised with the first P-CSCF address within the Protocol Configuration Options information element or within the IKEv2 configuration payload as the P-CSCF address having the highest priority; and
- B) if the UE uses RFC 6223 [143] as part of P-CSCF restoration procedures, and the P-CSCF fails to respond to keep-alive requests, then the UE shall acquire a different P-CSCF address using any of the methods described in the subclause R.2.2.1.

When the UE has acquired the P-CSCF address, the UE shall perform an initial registration as specified in subclause 5.1.

**NOTE:** For UEs using procedure A described above, the network ensures that P-CSCF address(es) received in the Protocol Configuration Options information element during TWAG initiated PDN connectivity modification procedure (in trusted non-3GPP access network), and P-CSCF address(es) received in the P-CSCF\_IP6\_ADDRESS attribute, the P-CSCF\_IP4\_ADDRESS attribute or both during ePDG initiated modification (in untrusted non-3GPP access network) are sent only during P-CSCF restoration procedures as defined in subclause 5 of 3GPP TS 23.380 [7D].

## R.2.2.2 Void

## R.2.2.3 IP-CAN support of DHCP based P-CSCF discovery

When using WLAN IP access via S2c to access the EPC, the Home Agent (HA) in case of Mobile IP with reverse tunneling, can forward the packet to one or more local DHCP servers, or relay the packet to a specific DHCP server. The HA in case of Mobile IP with reverse tunnelling, does not forward the DHCPINFORM (or Information-Request) to any UE.

**NOTE 1:** For forwarding the DHCPINFORM or Information-Request, the HA in case of Mobile IP with reverse tunnelling, does not change the destination IP address of the packet.

**NOTE 2:** For relaying the DHCPINFORM or Information-Request, the HA in case of Mobile IP with reverse tunnelling inserts a DHCP server's IP address in the destination IP address field of the packet.

## R.2.2.4 Void

## R.2.2.5 Tunnel procedures for media

### R.2.2.5.1 General requirements

The UE can establish media streams that belong to different SIP sessions on the same tunnel when accessing the EPC via untrusted WLAN.

During establishment of a session, the UE establishes data stream(s) for media related to the session. When using untrusted WLAN IP access via S2c to access the EPC, such data stream(s) may result in activation of additional IPsec ESP security associations (tunnels).

If the capabilities of the originating UE, or operator policy at the ePDG prevents the originating UE from establishment of additional IPsec ESP security associations (tunnels) according to the media grouping attributes given by the P-CSCF in accordance with RFC 3524 [54], the UE will not establish such grouping of media streams. Instead, the originating UE shall negotiate media parameters for the session according to RFC 3264 [27B].

If the capabilities of the terminating UE or operator policy at the ePDG prevents the originating UE from establishment of additional IPsec ESP security associations (tunnels) according to the media grouping attributes given by the P-CSCF in accordance with RFC 3524 [54], the UE will not establish such grouping of media streams. Instead, the terminating UE shall handle such SDP offers in accordance with RFC 3388 [53].

The UE can receive a media authorization token in the P-Media-Authorization header field from the P-CSCF according to RFC 3313 [31]. If a media authorization token is received in the P-Media-Authorization header field when a SIP session is initiated, the UE shall reuse the existing tunnel and ignore the media authorization token.

### R.2.2.5.1A Modification of tunnel for media by the UE

The tunnel modification procedure for the UE shall follow the procedures specified in 3GPP TS 24.302 [8U]. If the UE supports the Fixed Access Broadband interworking, the modification of tunnel specified in 3GPP TS 24.139 [8X] shall be applied.

### R.2.2.5.1B Modification of tunnel for media by the network

The UE shall follow the procedure specified in 3GPP TS 24.302 [8U] for the modification of tunnel. If the UE supports the Fixed Access Broadband interworking, the modification of tunnel specified in 3GPP TS 24.139 [8X] shall be applied.

If the UE attaches to the EPC via S2b using untrusted WLAN IP access, and IKEv2 multiple bearer PDN connectivity is used in the PDN connection according to 3GPP TS 24.302 [8U], then:

- 1) if:
  - A) an additional IPSec ESP tunnel is established according to 3GPP TS 24.302 [8U]; or
  - B) an IPSec ESP tunnel is modified according to 3GPP TS 24.302 [8U];

the UE shall, based on the information contained in the TFT Notify payload, correlate the media IPSec ESP tunnel with SDP media descriptions of a currently ongoing SIP session establishment or SIP session modification.

### R.2.2.5.1C Deactivation of tunnel for media

Not applicable.

### R.2.2.5.2 Special requirements applying to forked responses

Since the UE is unable to perform bearer modification, forked responses place no special requirements on the UE.

### R.2.2.5.3 Unsuccessful situations

Not applicable.

## R.2.2.6 Emergency service

### R.2.2.6.1 General

In this release of the specification, a WLAN, conforming to the requirements in this annex, defines emergency bearers. Emergency session is supported over the WLAN access if the UE has failed or has not been able to use 3GPP access to set up an emergency session as described in 3GPP TS 23.167 [4B] annex J.

IMS emergency session is also supported for UEs with unavailable IMSI (i.e. a UE without USIM) or unauthenticated IMSI. Some jurisdictions allow emergency calls to be made when the UE does not contain an ISIM or USIM, or where the credentials are not accepted.

When the UE is attached over a WLAN access and detects an emergency call attempt, if the UE supports the `emerg-non3gpp` timer defined in table 7.8.1, the UE shall start the `emerg-non3gpp` timer when starting a domain selection searching for a 3GPP access usable to establish an emergency call. The UE shall stop the timer when a 3GPP access supporting emergency call is found. When the `emerg-non3gpp` timer expires, the UE shall consider that it has failed to use 3GPP access to setup the emergency call and shall attempt to setup the emergency call over the available WLAN access.

The UE may support being configured for the `emerg-non3gpp` timer using one or more of the following methods:

- a) the `Timer_Emerg_non3gpp` leaf of the `EFIMSCConfigData` file described in 3GPP TS 31.102 [15C];
- b) the `Timer_Emerg_non3gpp` leaf of the `EFIMSCConfigData` file described in 3GPP TS 31.103 [15B]; and
- c) the `Timer_Emerg_non3gpp` leaf of 3GPP TS 24.167 [8G].

EPC procedures for emergency session using WLAN are defined for both trusted WLAN access via S2a, depending on the TWAN usage mode, and untrusted WLAN access via S2b to access EPC.

When the IM CN subsystem is selected as the domain for the emergency call attempt, and the UE uses:

- untrusted WLAN access via S2b, the UE determines that the EPC supports emergency bearer services by selecting or using an ePDG that has indicated its capability of support for emergency services, as specified in subclause 7.2.1A of 3GPP TS 24.302 [8U]; or
- trusted WLAN access via S2a, the UE determines that the EPC, accessed in usage modes multi-connection mode or single-connection mode, supports emergency bearer services if the CONNECTION\_MODE\_CAPABILITY item in the EAP-Request/AKA'-Challenge message indicates support of emergency services, as specified in 3GPP TS 24.302 [8U].

When the IM CN subsystem is selected as the domain for the emergency call attempt, and the UE uses untrusted WLAN access via S2b, the UE determines whether it is currently attached to its home operator's network (e.g. HPLMN) or not (e.g. VPLMN) after it has determined that the core network supports emergency bearer services.

When establishing an IMS emergency session using trusted WLAN access via S2a, the UE shall establish an IMS emergency session over trusted WLAN access depending on the usage mode used to access EPC. When using the usage mode single-connection mode, subclause 6.4.2.6.2A of 3GPP TS 24.302 [8U] applies. When using the usage mode multi-connection mode, subclause 6.4.2.6.3A of 3GPP TS 24.302 [8U] applies. The procedures for attaching to the EPC via S2a using a trusted WLAN IP access, as described in subclause R.2.2.1 of this specification apply accordingly.

When establishing an IMS emergency session using untrusted WLAN access via S2b, the UE shall establish an IMS emergency session over untrusted non-3GPP access as specified in 3GPP TS 24.302 [8U]. The procedures for attaching to the EPC via S2b using untrusted WLAN IP access, as described in subclause R.2.2.1 of this specification apply accordingly.

If the ME is equipped with a UICC, in order to find out whether the UE is attached to the home PLMN or to the visited PLMN, the UE shall compare the MCC and MNC values derived from its IMSI with the MCC and MNC of the PLMN the UE is attached to. If the MCC and MNC of the PLMN the UE is attached to do not match with the MCC and MNC derived from the IMSI, then for the purposes of emergency calls in the IM CN subsystem the UE shall consider to be attached to a VPLMN. If the ME is not equipped with a UICC, the procedure to find out whether the UE is attached to the home PLMN or to the visited PLMN for the purpose of emergency calls in the IM CN subsystem, is implementation specific.

NOTE 1: The UE verifies if a detected emergency number is still present in the Extended Local Emergency Number List applicable to the PLMN it is currently using. It is possible for the number to no longer be present in the Extended Local Emergency Number List if:

- the PLMN attached to relies on the Local Emergency Number List for deriving a URN; or
- the previously received Extended Emergency Number List Validity field indicated "Extended Local Emergency Numbers List is valid only in the PLMN from which this IE is received".

If the UE detected an emergency number, the UE subsequently uses a different PLMN than the PLMN from which the UE received the last Extended Local Emergency Number List:

NOTE 2: The UE has either attached to or authenticated (e.g. due to EAP-3GPP-LimitedService based access authentication, see 3GPP TS 24.302 [8U]) with a PLMN via WLAN prior to detecting the emergency number or because of detecting the emergency number.

- the dialled number is not stored in the ME, in the USIM and in the Local Emergency Number List;

then:

- a) if the UE supports provision and handling of local emergency numbers as defined in 3GPP TS 24.302 [8U], the UE has received the local emergency numbers using any of the methods defined in subclause 4.7 in 3GPP TS 24.302 [8U], the dialled number matches a received local emergency number, then the UE derives a URN as defined in 3GPP TS 24.302 [8U] or using the procedures in subclause R.2.2.6.1A, depending on the method used to provision the local emergency number;
- b) otherwise, the UE shall attempt UE procedures for SIP that relate to emergency using emergency service URN "urn:service:sos".

If the dialled number is equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]), then the UE shall recognize such a number as for an emergency call and:

- if the dialled number is equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform either procedures in the subclause R.2.2.6.1B or the procedures in subclause R.2.2.6.1A; and
- if the dialled number is not equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform procedures in the subclause R.2.2.6.1B.

If the dialled number is not equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]) and:

- if the dialled number is equal to an emergency number stored in the ME, in the USIM or in the Local Emergency Number List (as defined in 3GPP TS 24.008 [8]), then the UE shall recognize such a number as for an emergency call and performs the procedures in subclause R.2.2.6.1A.

Once IPsec tunnel setup is completed, the UE shall follow the procedures described in subclause R.2.2.1 of this specification for establishment of IP-CAN bearer and P-CSCF discovery accordingly.

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, if:

- the 380 (Alternate Service) response contains a Contact header field;
- the value of the Contact header field is a service URN; and
- the service URN has a top-level service type of "sos";

then the UE determines that "emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.3.1, if the 380 (Alternate Service) response does not contain a Contact header field with service URN that has a top-level service type of "sos", then the UE determines that "no emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, the UE shall proceed as follows:

- 1) if a 3GPP access network is available and the UE has not already attempted to use a 3GPP access network to set up an emergency session as described in 3GPP TS 23.167 [4B] annex J, when the UE selects a domain in accordance with the conventions and rules specified in 3GPP TS 22.101 [1A] and 3GPP TS 23.167 [4B], the UE shall attempt to select a domain of the 3GPP access network, and:
  - if the CS domain is selected, the UE behaviour is defined in subclause 7.1.2 of 3GPP TS 23.167 [4B] and in annex B, annex L or annex U; and
  - if the IM CN subsystem is selected, the UE shall apply the procedures in subclause 5.1.6 with the exception of selecting a domain for the emergency call attempt;

In addition, when the UE determines that "it has not been able to use 3GPP access to set up an emergency session" in accordance with subclause J.1 of 3GPP TS 23.167 [4B], the UE shall apply the procedures in subclause 5.1.6 using WLAN, with the exception of selecting a domain for the emergency call attempt; and

- 2) if a 3GPP access network is not available, then the UE shall apply the procedures in subclause 5.1.6 using WLAN, with the exception of selecting a domain for the emergency call attempt.

When the emergency session ends, the UE:

- 1) shall release the tunnel as described in 3GPP TS 24.302 [8U]; and
- 2) if EPC via WLAN is the preferred IP-CAN to access IM CN subsystem or if no 3GPP access is available:
  - a) if the UE did not select the currently selected ePDG using procedures for selection of ePDG for non-emergency services, shall select an ePDG for non-emergency services as described in 3GPP TS 24.302 [8U];
  - b) if the UE does not have an IP-CAN bearer for non-emergency SIP signalling, shall follow the procedures described in subclause R.2.2.1 for establishment of an IP-CAN bearer for SIP signalling and P-CSCF discovery; and

- c) if the UE determines that its contact associated with the IP-CAN bearer for non-emergency SIP signalling is not bound to a public user identity, shall perform an initial registration as specified in subclause 5.1.1.2 using the IP-CAN bearer for SIP signalling.

### R.2.2.6.1A Type of emergency service derived from emergency service category value

The type of emergency service for an emergency number is derived from the settings of the emergency service category value (bits 1 to 5 of the emergency service category value as specified in subclause 10.5.4.33 of 3GPP TS 24.008 [8]). Table R.2.2.6.1 below specifies mappings between a type of emergency service and an emergency service URN. The UE shall use the mapping to match an emergency service URN and a type of emergency service. If a dialled number is an emergency number but does not map to a type of emergency service the service URN shall be "urn:service:sos".

**Table R.2.2.6.1: Mapping between type of emergency service and emergency service URN**

| Type of emergency service | Emergency service URN     |
|---------------------------|---------------------------|
| Police                    | urn:service:sos.police    |
| Ambulance                 | urn:service:sos.ambulance |
| Fire Brigade              | urn:service:sos.fire      |
| Marine Guard              | urn:service:sos.marine    |
| Mountain Rescue           | urn:service:sos.mountain  |

NOTE 1: It is not possible for a UE to indicate more than one type of emergency service in an emergency service URN.

If:

- the UE considers itself in the country of the HPLMN;

NOTE 2: It is out of scope of the present annex to define how the UE determines whether it considered itself in the country of the HPLMN. When the UE is in coverage of a 3GPP RAT, it can, for example, use the information derived from the available PLMN(s). In this case, the UE can match the MCC broadcasted on the BCCH of the 3GPP access against the UE's IMSI to determine if they belong to the same country, as defined in 3GPP TS 23.122 [4C]. If the UE is not in coverage of a 3GPP RAT, the UE can use other techniques, including user-provided location, for determining whether it is located in its home country or not.

- multiple types of emergency services can be derived for a dialled number from the information configured on the USIM; and
- no IP-CAN provided a local emergency number that matches the dialled number (see subclause 5.1.6.1);

NOTE 3: If the Non-3GPP emergency number indicator within the Non-3GPP NW provided policies IE (see 3GPP TS 24.008 [8]) provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers permitted", the UE also considers WLAN provided local emergency numbers (see 3GPP TS 24.302 [8U], subclause 4.7). If the Non-3GPP NW provided policies IE provided through registration procedures over 3GPP access is set to "use of non-3GPP emergency numbers not permitted", the UE does not consider WLAN provided local emergency numbers. If the Non-3GPP NW provided policies IE is not provided through registration procedures over 3GPP access, the UE does not consider WLAN provided local emergency numbers.

NOTE 4: A UE, only connected to a PLMN through non-3GPP access, considers the WLAN provided local emergency numbers if the applicable conditions in subclause 4.7 of 3GPP TS 24.302 [8U], are met.

then the UE shall map any one of these types of emergency service to an emergency service URN as specified in table R.2.2.6.1.

If the UE considers itself in the country of the HPLMN and an IP-CAN provided a local emergency number that matches the dialled number (see subclause 5.1.6.1), and if the UE:

- can derive one or more types of emergency service from the information received from the IP-CAN for the dialled number and the UE cannot derive types of emergency service from the information configured on the USIM for the dialled number; or

- derives identical types of emergency service from both the information received from the IP-CAN for the dialled number and from the information configured on the USIM for the dialled number;

then the UE shall map any one of these emergency service types to an emergency service URN as specified in table R.2.2.6.1.

NOTE 5: How the UE resolves clashes where an emergency number is associated with one or more different types of emergency service configured in the USIM and in information received from an IP-CAN, is implementation dependent.

#### R.2.2.6.1B Type of emergency service derived from extended local emergency number list

The Extended Local Emergency Number List (defined in 3GPP TS 24.301 [8J]) can contain sub-services of the associated emergency service URN for the detected emergency number.

If:

- the length of sub-services field is greater than "0", the UE shall construct the emergency service URN using "urn:service:sos" followed by adding a dot followed by the content of the sub-services field; and
- the length of sub-services field is "0", the UE shall use the emergency service URN "urn:service:sos".

EXAMPLE 1: For a detected number, if the sub-service is "gas", then the UE constructs "urn:service:sos.gas" as the associated emergency service URN.

EXAMPLE 2: For a detected number, if no sub-service is provided, then the UE uses "urn:service:sos" as the associated emergency service URN.

#### R.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### R.2.2.6.3 Current location discovery during an emergency call

The UE may support the current location discovery during an emergency call specified in subclause 5.1.6.8.2, subclause 5.1.6.8.3, subclause 5.1.6.8.4, and subclause 5.1.6.12.

---

## R.2A Usage of SDP

### R.2A.0 General

Not applicable.

### R.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

If the UE is attached to the EPC via S2b using untrusted WLAN IP access, and IKEv2 multiple bearer PDN connectivity is used in the PDN connection according to 3GPP TS 24.302 [8U], then:

- 1) if an additional IPSec ESP tunnel is established according to 3GPP TS 24.302 [8U] and the related SDP media description needs to be changed, the UE shall update the related SDP information by sending a new SDP offer within a SIP request, which is sent over the existing SIP dialog; and
- 2) if an IPSec ESP tunnel is modified according to 3GPP TS 24.302 [8U] and the related SDP media description need to be changed, the UE shall update the related SDP information by sending a new SDP offer within a SIP request, that is sent over the existing SIP dialog.

NOTE: The UE can decide to indicate additional media streams as well as additional or different codecs in the SDP offer than those used in the already ongoing session.

## R.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

## R.2A.3 Emergency service

No additional procedures defined.

---

# R.3 Application usage of SIP

## R.3.1 Procedures at the UE

### R.3.1.0 Registration and authentication

Editor's note: [WID: TURAN-CT, CR#4993]: Best usage of this FTT-IMS establishment is when the UE does not establish the IKEv2 security association which is an option not specified in subclause R.2.2.1. This requires further study.

In order to reach the IM CN subsystem in some untrusted access networks, the UE may support:

- address and/or port number conversions provided by a NA(P)T or NA(P)T-PT as described in annex F and annex K; or
- the IP UE requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y], which is applicable to direct access to an external IP network and not applicable to access through a PLMN.

If a UE supports one or both of these capabilities then a UE may progressively try them to overcome failure to reach the IPM CN subsystem. Use of these capabilities shall have the following priority order:

- 1) UE does not use capability because reaching the IMS without an intervening NA(P)T, NA(P)T-PT, or tunnel is preferred.
- 2) UE may use address and/or port number conversions provided by a NA(P)T or NA(P)T-PT as described in either annex F or annex K.
- 3) UE may use the UE requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y]. If the UE uses the UE-requested FTT-IMS establishment procedure specified in 3GPP TS 24.322 [8Y], the UE considers itself to:
  - be configured to send keep-alives;
  - be directly connected to an IP-CAN for which usage of NAT is defined; and
  - be behind a NAT.

Optional procedures apply when the UE is supporting traversal of restrictive non-3GPP access network using STUN/TURN/ICE, as follows:

- a) the protection of SIP messages is provided by utilizing TLS as defined in 3GPP TS 33.203 [19];
- b) the mechanisms specified in this annex shall only be applicable when the IP traffic to the IMS core does not traverse through the Evolved Packet Core (EPC);

- c) the UE shall establish the TLS connection to the P-CSCF on port 443 as defined in 3GPP TS 33.203 [19]. The UE shall use SIP digest with TLS for registration as specified in subclause 5.1. If the TLS connection is established successfully, the UE sends SIP signalling over the TLS connection to the P-CSCF;
- d) the UE shall support the keep-alive procedures described in RFC 6223 [143];

NOTE 1: If the UE is configured to use an HTTP proxy, the UE use the HTTP CONNECT method specified in RFC 2817 [220] to request the HTTP proxy to establish the TCP connection with the P-CSCF. Once the UE has received a positive reply from the proxy that the TCP connection has been established, the UE initiates the TLS handshake with the P-CSCF and establishes the TLS connection.

- e) the procedures described in subclause K.5.2 apply with the additional procedures described in the present subclause;
- f) when using the ICE procedures for traversal of restrictive non-3GPP access network, the UE shall support the ICE TCP as specified in RFC 6544 [131] and TURN TCP as specified in RFC 6062 [221].
- g) if the UE is configured to use TURN over TCP on port 80, the UE shall establish the TCP connection to TURN server on port 80. If the UE is configured to use TURN over TLS on port 443, the UE shall establish the TLS connection to the TURN server on port 443 as defined in 3GPP TS 33.203 [19]. If the UE is configured to use both, the UE should prefer to use TURN over TCP on port 80 to avoid TLS overhead;
- h) if the connection is established successfully, the UE sends TURN control messages and media packets over the connection as defined in RFC 5766 [101].

NOTE 2: If the UE is configured to use an HTTP proxy, the UE use the HTTP CONNECT method specified in RFC 2817 [220] to request the HTTP proxy to establish the TCP connection with the TURN server. Then, if the UE is configured to use TURN over TLS on port 443 and the UE has received a positive reply from the proxy that the TCP connection has been established, the UE initiates the TLS handshake with the TURN server and establishes the TLS connection.

The UE shall perform reregistration of a previously registered public user identity bound to any one of its contact addresses when changing to an IP-CAN for which usage is specified in annex B, annex L or annex U. The reregistration is performed using the new IP-CAN.

NOTE 3: This document does not specify how the UE detects that the used IP-CAN has changed. The information that is forcing the reregistration is also used to generate the content for the P-Access-Network-Info header field.

NOTE 4: The UE will send the reregistration irrespective of whether it has a SIP dialog or not.

### R.3.1.0a IMS\_Registration\_handling\_policy

Not applicable.

### R.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

#### R.3.1.1A Cellular-Network-Info header field

The UE:

- 1) using the Evolved Packet Core (EPC) via Untrusted Wireless Local Access Network (WLAN) as IP-CAN to access the IM CN subsystem; and
- 2) supporting one or more cellular radio access technology (e.g. E-UTRAN);

shall always include the Cellular-Network-Info header field specified in subclause 7.2.15, if the information is available, in every request or response in which the P-Access-Network-Info header field is present.

NOTE: If the Cellular-Network-Info header field includes radio cell identity, then the Cellular-Network-Info header field populated by the UE that supports Multi-RAT Dual Connectivity with the EPC as described in 3GPP TS 37.340 [264] will contain the information about the radio cell identity of the Master RAN node that is serving the UE.

### R.3.1.2 Availability for calls

Not applicable.

### R.3.1.2A Availability for SMS

Void.

### R.3.1.3 Authorization header field

When using SIP digest or SIP digest without TLS, the UE need not include an Authorization header field on sending a REGISTER request, as defined in subclause 5.1.1.2.1.

NOTE: In case the Authorization header field is absent, the mechanism only supports that one public user identity is associated with only one private user identity. The public user identity is set so that it is possible to derive the private user identity from the public user identity by removing SIP URI scheme and the following parts of the SIP URI if present: port number, URI parameters, and To header field parameters. Therefore, the public user identity used for registration in this case cannot be shared across multiple UEs. Deployment scenarios that require public user identities to be shared across multiple UEs that don't include an private user identity in the initial REGISTER request can be supported as follows:

- Assign each sharing UE a unique public user identity to be used for registration,
- Assign the shared public user identities to the implicit registration set of the unique registering public user identities assigned to each sharing UE.

### R.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### R.3.1.5 3GPP PS data off

Not applicable.

### R.3.1.6 Transport mechanisms

The transport mechanisms as defined in subclause 4.2A are used with an additional requirement:

- a) If the UE has attached to the EPC via untrusted non-3gpp access and uses IPSec tunnel mode, in order to reduce the risk of UDP fragmentation, the UE shall decrement the IPSec tunnel overhead from the path MTU between the UE and the ePDG prior applying the transport selection for SIP requests as defined in RFC 3261 [26] subclause 18.1.1.

NOTE: The method for discovering the maximum transmission unit for non-3GPP is implementation dependent and out of scope of 3GPP.

### R.3.1.7 RLOS

Not applicable.

## R.3.2 Procedures at the P-CSCF

### R.3.2.0 Registration and authentication

The P-CSCF may support UEs connected via restrictive non-3GPP access network.

If the P-CSCF supports UEs connected via restrictive non-3GPP access network, when the P-CSCF receives a 200 (OK) response to a REGISTER request, if the contact address of REGISTER request contains an IP address assigned by the EFTF, and the UE's Via header field contains a "keep" header field parameter, then the P-CSCF shall add a value to the "keep" header field parameter of the UE's Via header field of the 200 (OK) response as defined in RFC 6223 [143].

Optional procedures apply when the P-CSCF is supporting traversal of restrictive non-3GPP access network using STUN/TURN/ICE, as follows:

**NOTE:** In this scenario, the restrictive non-3GPP access network coexists with NA(P)T device located in the customer premises domain:

- a) the protection of SIP messages is provided by utilizing TLS as defined in 3GPP TS 33.203 [19];
- b) the P-CSCF supporting these additional procedures should use SIP digest with TLS as defined in subclause 5 and the P-CSCF should insert an IMS-ALG on the media plane;
- c) the mechanisms specified in this annex shall only be applicable when the IP traffic to the IMS core does not traverse through the Evolved Packet Core (EPC);
- d) the P-CSCF shall support the procedures defined in subclause 5.2, with the exception that the P-CSCF shall use SIP over TLS on port 443 as defined in 3GPP TS 33.203 [19];
- e) when the UE has indicated support of the keep-alive mechanism defined in RFC 6223 [143], the P-CSCF shall indicate to the UE that it supports the keep-alive mechanism; and
- f) the IMS-ALG in the P-CSCF shall support ICE procedures, as defined in subclause 6.7.2.7.

### R.3.2.1 Determining network to which the originating user is attached

If the P-CSCF is configured to handle emergency requests, in order to determine from which network the request was originated the P-CSCF shall,

- if PCRF is used for this UE and 3GPP-User-Location-Info as specified in 3GPP TS 29.214 [13D] is available (see subclause 5.2.1), check the MCC and MNC received in 3GPP-User-Location-Info; and
- if PCRF is not used for this UE or 3GPP-User-Location-Info is not available, check the MCC and MNC fields received in the Cellular-Network-Info header field in the emergency request.

**NOTE 1:** The Cellular-Network-Info header field includes the MCC and the MNC of the cellular radio access network on which the UE most recently camped. The UE is not necessarily attached to a network via that cell or still camped on that cell.

**NOTE 2:** The above check can be against more than one MNC code stored in the P-CSCF.

### R.3.2.2 Location information handling

Void.

### R.3.2.3 Prohibited usage of PDN connection for emergency bearer services

If the P-CSCF detects that a UE uses a PDN connection for emergency bearer services for a non-emergency REGISTER request, the P-CSCF shall reject that request by a 403 (Forbidden) response.

**NOTE:** By assigning specific IP address ranges for a PDN connection for emergency bearer services and configuring those ranges in P-CSCF, the P-CSCF can detect based on the registered Contact address if UE uses an emergency PDN connection for initial registration.

### R.3.2.4 Void

### R.3.2.5 Void

### R.3.2.6 Resource sharing

If PCC is supported for this access technology a P-CSCF supporting resource sharing shall apply the procedures in subclause L.3.2.6.

NOTE: Resource sharing has in this version of the specification no meaning in the WLAN IP CAN. However, since transfer to EPS IP CAN is seamless from P-CSCF point of view the resource sharing options used over the Rx interface when the UE is attached to the WLAN IP CAN could be used when the UE moves to EPS IP CAN and since Rx requires the resource sharing options to be included in the initial AAR the resource sharing options need to be included also when the UE attached to the WLAN IP CAN initiates or receives a INVITE request.

### R.3.2.7 Priority sharing

If PCC is supported for this access technology a P-CSCF supporting priority sharing and if according to operator policy shall apply the procedures in subclause L.3.2.7.

### R.3.2.8 RLOS

Not applicable.

## R.3.3 Procedures at the S-CSCF

### R.3.3.1 Notification of AS about registration status

Not applicable.

### R.3.3.2 RLOS

Not applicable.

---

## R.4 3GPP specific encoding for SIP header field extensions

### R.4.1 Void

---

## R.5 Use of circuit-switched domain

Void.

---

# Annex S (normative): IP-Connectivity Access Network specific concepts when using DVB-RCS2 to access IM CN subsystem

## S.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is DVB-RCS2 satellite access network.

DVB-RCS2 (Second Generation DVB Interactive Satellite System) is a term referring to the ETSI standard ETSI TS 101 454-1 [193], ETSI EN 301 545-2 [194], ETSI TS 101 545-3 [195] for 2<sup>nd</sup> generation DVB satellite based access network technology with a return channel for two-way communication.

---

## S.2 DVB-RCS2 aspects when connected to the IM CN subsystem

### S.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the DVB-RCS2 satellite access network to provide packet-mode communication between the UE and the IM CN subsystem.

From the perspective of the UE, the necessary IP-CAN bearer for signalling is transparently available to the UE.

The UE is not directly involved in requests for IP-CAN bearer(s) for media flow(s). The IM CN interacts with the PCRF in the DVB-RCS2 IP-CAN to establish IP-CAN bearer(s) for media flow(s), on behalf of the UE.

### S.2.2 Procedures at the UE

#### S.2.2.1 Activation and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall:

- a) establish a connection to a DVB-RCS2 RCST depending on local configuration; the RCST shall have completed the RCST commissioning and initialization procedures as described in ETSI TS 101 545-3 [195], and thus have achieved IP connectivity to the NCC of an SVN;
- b) obtain an IP address using the standard IETF protocols (e.g., DHCP or IPCP). The UE shall fix the obtained IP address throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the last deregistration; and
- c) acquire a P-CSCF address(es), according to one of the methods described in subclause 9.2.1; the method available to the UE is determined by the SVN to which the RCST is connected.

#### S.2.2.1A Modification of IP-CAN bearer used for SIP signalling

Not applicable.

#### S.2.2.1B Re-establishment of IP-CAN bearer used for SIP signalling

Not applicable.

## S.2.2.1C P-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure uses the keep-alive procedures described in RFC 6223 [143].

If the P-CSCF fails to respond to keep-alive requests the UE shall acquire a different P-CSCF address using any of the methods described in the subclause S.2.2.1 and perform an initial registration as specified in subclause 5.1.

### S.2.2.2 Void

### S.2.2.3 Void

### S.2.2.4 Void

## S.2.2.5 Handling of the IP-CAN for media

### S.2.2.5.1 General requirements

The UE does not directly request resources for media flow(s).

#### S.2.2.5.1A Activation or modification of IP-CAN for media by the UE

Not applicable.

#### S.2.2.5.1B Activation or modification of IP-CAN for media by the network

Not applicable.

#### S.2.2.5.1C Deactivation of IP-CAN for media

Not applicable.

### S.2.2.5.2 Special requirements applying to forked responses

The UE does not directly request resources for media flow(s). As a result there are no special UE requirements applying to forked responses.

### S.2.2.5.3 Unsuccessful situations

Not applicable.

## S.2.2.6 Emergency service

### S.2.2.6.1 General

Emergency service is not supported when the IP-CAN is a DVB-RCS2 satellite access network.

#### S.2.2.6.1A Type of emergency service derived from emergency service category value

Not applicable.

#### S.2.2.6.1B Type of emergency service derived from extended local emergency number list

Not applicable.

#### S.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### S.2.2.6.3 Current location discovery during an emergency call

Void.

---

## S.2A Usage of SDP

### S.2A.0 General

Not applicable.

### S.2A.1 Impact on SDP offer / answer of activation or modification of satellite bearer for media by the network

Not applicable.

### S.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

### S.2A.3 Emergency service

No additional procedures defined.

---

## S.3 Application usage of SIP

### S.3.1 Procedures at the UE

#### S.3.1.0 Void

#### S.3.1.0a IMS\_Registration\_handling policy

Not applicable.

#### S.3.1.1 P-Access-Network-Info header field

The UE may, but need not, include the P-Access-Network-Info header field where indicated in subclause 5.1.

#### S.3.1.1A Cellular-Network-Info header field

Not applicable.

### S.3.1.2 Availability for calls

Not applicable.

### S.3.1.2A Availability for SMS

Void.

### S.3.1.3 Authorization header field

Void

### S.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### S.3.1.5 3GPP PS data off

Not applicable.

### S.3.1.6 Transport mechanisms

No additional requirements are defined.

### S.3.1.7 RLOS

Not applicable.

## S.3.2 Procedures at the P-CSCF

### S.3.2.0 Registration and authentication

Void.

### S.3.2.1 Determining network to which the originating user is attached

In order to determine from which network the request was originated the P-CSCF shall check if the location information received in the network provided and/or UE provided "dvb-rcs2-node-id" parameter in the P-Access-Network-Info header field(s) indicates that the UE is connected to the same network as the P-CSCF or not.

NOTE 1: If local policy does not require the insertion of P-Access-Network-Info header field in the P-CSCF even if it is missing in the received initial request, the P-CSCF can assume that the request is initiated by a UE in the same network as the P-CSCF.

NOTE 2: If the location information in the network provided and UE provided "dvb-rcs2-node-id" parameters (in a request that includes two P-Access-Network-Info header fields) is contradictory, or the two P-Access-Network-Info header fields indicate different access types the P-CSCF ignores either the network provided or the UE provided information according to operator policy.

### S.3.2.2 Location information handling

Upon receipt of an initial request for a dialog or standalone transaction or an unknown method, the P-CSCF based on local policy may include a P-Access-Network-Info header field. The value of the "dvb-rcs2-node-id" parameter shall be provided by the IP-CAN.

#### S.3.2.3 Void

#### S.3.2.4 Void

#### S.3.2.5 Void

#### S.3.2.6 Resource sharing

Not applicable.

#### S.3.2.7 Priority sharing

Not applicable.

#### S.3.2.8 RLOS

Not applicable.

### S.3.3 Procedures at the S-CSCF

#### S.3.3.1 Notification of AS about registration status

Not applicable

#### S.3.3.2 RLOS

Not applicable.

---

## S.4 3GPP specific encoding for SIP header field extensions

### S.4.1 Void

---

## S.5 Use of circuit-switched domain

There is no CS domain in this access technology.

---

# Annex T (Normative): Network policy requirements for the IM CN subsystem

## T.1 Scope

This annex details areas where network policy is subject to additional requirements to those specified in the main part of this document.

---

## T.2 Application of network policy for the support of transcoding

When providing transcoding functions at the P-CSCF, at the IBCF and at an AS, the set of codecs to be forwarded as the SDP offer to the remote user is subject to network policy. In order to give support to the codecs and media quality originally requested by the offerer, the network policy shall meet the following requirements.

NOTE 1: RFC 3264 [27B] recommends to list codecs in priority order, so by adding network inserted codecs to the end of the codec list will give higher priority to previous codecs that might have been inserted by the originating UE.

- A) An intermediate entity should attempt to support the original request for codecs from the UE.
- B) An intermediate entity should only remove a codec from the codec list to meet policy requirements of the local access of the user.
- C) A modification (i.e. any combination of reordering, removal or addition) to the codec list should only be made, such that the resultant SDP offer / answer exchange results in media of equal or better end-to-end quality than if the modification had not been made, subject to policy restrictions of the access of the local user.

NOTE 2: Transcoding between codecs of higher quality can provide better end-to-end quality than using a common codec of lower quality.

- D) A modification (i.e. any combination of reordering, removal or addition) to the codec list should only be made, such that the resultant SDP offer / answer exchange prefers solutions that do not use a transcoder rather than ones that do use transcoder, subject to meeting the policy restrictions in B) and meeting the best end-to-end media quality in C) above.
- E) Additions to the codec list that are provided by the network entity shall be supported by transcoding between at least one of the offered codecs contained in the SDP offer and the added codecs.
- F) An intermediate entity shall not insert a codec to the codec list if end-to-end media security mechanism is required for the related media.
- G) If an intermediate entity performs transcoding during an ongoing session and receives a SIP message containing a subsequent SDP offer including the codec that is currently in use on the incoming call leg, the entity should include the codec that is currently in use on the outgoing call leg when forwarding the SIP message.
- H) If an intermediate entity performs transcoding during an ongoing session and receives a SIP message containing a subsequent SDP offer not including the codec that is currently in use on the incoming call leg, the entity should include the codec that is currently in use on the outgoing call leg when forwarding the SIP message, subject to meeting the policy restrictions in E).
- I) If an intermediate entity does not perform transcoding during an ongoing session and receives a SIP message containing a subsequent SDP offer including the codec that is currently in use, the entity should not add any codecs in the subsequent SDP offer.

---

# Annex U (normative): IP-Connectivity Access Network specific concepts when using 5GS to access IM CN subsystem

## U.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IP Multimedia (IM) Core Network (CN) subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is 5G System (5GS). The 5GS IP-CAN has a 5GS core network which can be supported by a NG-RAN.

---

## U.2 IP-CAN aspects when connected to the IM CN subsystem

### U.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by 5GS to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause.

When using the 5GS, each IP-CAN bearer is provided by a 5GS QoS flow.

### U.2.2 Procedures at the UE

#### U.2.2.1 Establishment of IP-CAN bearer and P-CSCF discovery

Prior to communication with the IM CN subsystem, the UE shall:

- a) if not registered for 5GS services, perform a registration procedure in 5GS as specified in 3GPP TS 24.501 [258];
- b) ensure that a 5GS PDU session and a QoS flow used for SIP signalling of that PDU session is available. This 5GS QoS flow shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration. As a result, the 5GS PDU session provides the UE with information that makes the UE able to construct an IPv4 or an IPv6 address;

when establishing a 5GS PDU session, if a service which requires service continuity provided by SSC mode 1 as specified in 3GPP TS 23.501 [257], (e.g. IMS Multimedia Telephony Service as specified in 3GPP TS 24.173 [8H]), is to be used within that PDU session, the UE shall set SSC mode 1 for that PDU session;

when establishing a 5GS PDU session with a QoS flow used for SIP signaling, the UE shall indicate to the network, by setting the IM CN Subsystem Signalling Flag in the extended Protocol Configuration Options information element specified in 3GPP TS 24.501 [258] in the PDU SESSION ESTABLISHMENT REQUEST message, that the request is for SIP signalling;

- c) use the QoS flow associated with the default QoS rule for SIP signalling. The UE may also use this 5GS QoS flow for Domain Name Server (DNS) and Dynamic Host Configuration Protocol (DHCP) signalling; and
- d) acquire a P-CSCF address(es).

The methods for P-CSCF discovery are:

- I. When using IPv4, employ the DHCP RFC 2132 [20F], the DHCPv4 options for SIP servers RFC 3361 [35A], and RFC 3263 [27A] as described in subclause 9.2.1. When using IPv6, employ Dynamic Host Configuration Protocol for IPv6 (DHCPv6) RFC 3315 [40], the DHCPv6 options for SIP servers RFC 3319 [41] and DHCPv6 options for DNS RFC 3646 [56C] as described in subclause 9.2.1.
- II. Transfer P-CSCF address(es) within the 5GS PDU session establishment procedure.

The UE shall indicate the request for a P-CSCF address to the network within the extended Protocol Configuration Options information element of the PDU SESSION ESTABLISHMENT REQUEST message.

If the network provides the UE with a list of P-CSCF IPv4 or IPv6 addresses in the PDU SESSION ESTABLISHMENT ACCEPT message, the UE shall assume that the list is ordered top-down with the first P-CSCF address within the extended Protocol Configuration Options information element as the P-CSCF address having the highest preference and the last P-CSCF address within the extended Protocol Configuration Options information element as the P-CSCF address having the lowest preference.

III. The UE selects a P-CSCF from the list (see 3GPP TS 31.103 [15B]) stored in the ISIM.

IV. The UE selects a P-CSCF from the list in IMS management object.

The UE shall use method IV to select a P-CSCF, if

- a P-CSCF is to be discovered in the home network;
- the UE is roaming; and
- the IMS management object contains the P-CSCF list.

The UE shall use method III to select the P-CSCF, if:

- a P-CSCF is to be discovered in the home network;
- the UE is roaming;
- either the UE does not contain the IMS management object, or the UE contains the IMS management object but the IMS management object does not contain the P-CSCF list; and
- the ISIM residing in the UICC supports the P-CSCF list.

The UE can freely select method I or II for P-CSCF discovery, if:

- the UE is in the home network; or
- the UE is roaming and the P-CSCF is to be discovered in the visited network.

The UE can select method IV, if:

- the UE is in the home network; and
- the IMS management object contains the P-CSCF list.

In case method I is selected and several P-CSCF addresses or FQDNs are provided to the UE, the selection of P-CSCF address or FQDN shall be performed as indicated in RFC 3361 [35A] when using IPv4 or RFC 3319 [41] when using IPv6. If sufficient information for P-CSCF address selection is not available, selection of the P-CSCF address by the UE is implementation specific.

**NOTE:** The UE decides whether the P-CSCF is to be discovered in the serving network or in the home network based on local configuration, e.g. whether the application on the UE is permitted to use local breakout.

If the UE is designed to use I above, but receives P-CSCF address(es) according to II, then the UE shall either ignore the received address(es), or use the address(es) in accordance with II, and not proceed with the DHCP request according to I.

If the UE is configured to use Option II above and detects that all P-CSCFs known by the UE have been used when the UE selects a different P-CSCF as a result of:

- receiving 305 (Use Proxy) to the REGISTER request;

- receiving 504 (Server Time-out); or
- expiration of the timer F at the UE,

then unless the PDU session is in use by other applications, the UE shall:

- 1) release the PDU session of the 5GS QoS flow that is used only for the transport of SIP signalling and that are not used for other non-IMS applications, but shall not release emergency PDU session; and
- 2) unless the UE decides the service is no longer needed,
  - a) perform a new P-CSCF discovery procedure as described in subclause 9.2.1; and
  - b) perform the procedures for initial registration as described in subclause 5.1.1.2.

When using IPv4, the UE may request a DNS Server IPv4 address(es) via RFC 2132 [20F] or by the extended Protocol Configuration Options information element when establishing the PDU session according to 3GPP TS 24.501 [258].

When using IPv6, the UE may request a DNS Server IPv6 address(es) via RFC 3315 [40] and RFC 3646 [56C] or by the extended Protocol Configuration Options information element when establishing the PDU session according to 3GPP TS 24.501 [258].

When:

- the UE obtains a 5GS QoS flow used for SIP signalling by performing handover of the connection from another IP-CAN;
- IP address of the UE is not changed during the handover; and
- the UE already communicates with the IM CN subsystem via the connection with the other IP-CAN, e.g. the UE determines that its contact with host portion set to the UE IP address (or FQDN of the UE) associated with the connection with the other IP-CAN has been bound to a public user identity;

the UE shall continue using the P-CSCF address(es) acquired in the other IP-CAN.

### U.2.2.1A Modification of the PDU session of the 5GS QoS flow used for SIP signalling

The UE shall not modify the 5GS QoS flow from being used exclusively for SIP signalling.

When a 5GS QoS flow used for SIP signalling is established, the UE shall not set the IM CN Subsystem Signalling Flag in the extended Protocol Configuration Options information element specified in 3GPP TS 24.501 [258] of any subsequent PDU SESSION MODIFICATION REQUEST message for that DNN.

The UE shall ignore the IM CN Subsystem Signalling Flag if received from the network in the extended Protocol Configuration Options information element.

After the establishment of a 5GS QoS flow used for SIP signalling, the UE shall not indicate the request for a P-CSCF address to the network within the extended Protocol Configuration Options information element of any subsequent PDU SESSION MODIFICATION REQUEST message for that DNN.

The UE shall ignore P-CSCF address(es) if received from the network in the extended Protocol Configuration Options information element of a PDU SESSION MODIFICATION COMMAND message which is triggered by a PDU SESSION MODIFICATION REQUEST message.

### U.2.2.1B Re-establishment of the PDU session with the 5GS QoS flow used for SIP signalling

If the UE registered a public user identity with an IP address allocated for the DNN of the PDU session with the 5GS QoS flow used for SIP signalling, the PDU session with the 5GS QoS flow used for SIP signalling is deactivated as result of signalling from the network and:

- i) if the UE is required to perform an initial registration according to subclause U.3.1.2;

- ii) if the signalling from the network results in requiring the UE to initiate activation of the PDU session of the 5GS QoS flow used for SIP signalling; or
- iii) if the UE needs to continue having a public user identity registered with an IP address allocated for the DNN;

the UE shall:

- A) if the non-access stratum is performing the UE requested PDU session establishment procedure for the DNN triggered as result of the signalling from the network, wait until the UE requested PDU session establishment procedure for the DNN finish; and
- B) perform the procedures in subclause U.2.2.1, bullets a), b) and c).

If none of the bullets i), ii) and iii) of this subclause evaluate to true, or the procedures in bullet B) of this subclause were unable to ensure that the 5GS QoS flow used for SIP signalling is available or were unable to acquire any P-CSCF address(es):

- 1) if the SIP signalling was carried over a 5GS QoS flow not associated with the default QoS rule, the UE shall release all resources established as a result of SIP signalling by sending to the network either:
  - a) a PDU SESSION MODIFICATION REQUEST message, if there are 5GS QoS flows of this PDU session that are not related SIP sessions; or
  - b) a PDU SESSION RELEASE REQUEST message if all the 5GS QoS flows of this PDU session are related to SIP sessions.

If the 5GS QoS flow associated with default QoS rule used for SIP signalling was deactivated as described at the start of this subclause, and the procedures in bullet B) of this subclause ensured that the 5GS QoS flow used for SIP signalling is available and acquired the P-CSCF address(es), the UE shall perform a new initial registration according to subclause 5.1.1.2.

### U.2.2.1CP-CSCF restoration procedure

A UE supporting the P-CSCF restoration procedure performs one of the following procedures:

- A) if the UE used method II for P-CSCF discovery and if the UE receives one or more P-CSCF address(es) in the extended Protocol Configuration Options information element of a PDU SESSION MODIFICATION COMMAND message and the one or more P-CSCF address(es) do not include the address of the currently used P-CSCF, then the UE shall acquire a different P-CSCF address from the one or more P-CSCF address(es) in the PDU SESSION MODIFICATION COMMAND message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority.

If the UE used method II for P-CSCF discovery and if the UE has previously sent the "P-CSCF Re-selection support" PCO indicator at PDU session creation and if the UE receives one or more P-CSCF address(es) in the extended Protocol Configuration Options information element of a PDU SESSION MODIFICATION COMMAND message, then the UE shall acquire a P-CSCF address from the one or more P-CSCF address(es) in the PDU SESSION MODIFICATION COMMAND message. If more than one P-CSCF address with the same container identifier (i.e. "P-CSCF IPv6 Address" or "P-CSCF IPv4 Address") are included, then the UE shall assume that the more than one P-CSCF addresses with the same container identifier are prioritised with the first P-CSCF address with the same container identifier within the Protocol Configuration Options information element as the P-CSCF address with the highest priority;

- B) if the UE uses RFC 6223 [143] as part of P-CSCF restoration procedures, and if the P-CSCF fails to respond to a keep-alive request, then the UE shall acquire a different P-CSCF address using one of the methods I, III and IV for P-CSCF discovery described in the subclause U.2.2.1.

If the UE has an ongoing session and acquired the new P-CSCF address by using procedure A described above, the UE may wait until the UE has detected that the ongoing session has ended before performing an initial registration as specified in subclause 5.1.

In all other cases, when the UE has acquired the P-CSCF address, the UE not having an ongoing session shall perform an initial registration as specified in subclause 5.1.

NOTE 1: For UEs using procedure A described above, the network ensures that P-CSCF address(es) in the extended Protocol Configuration Options information element of a PDU SESSION MODIFICATION COMMAND message is sent only during P-CSCF restoration procedures as defined in subclause 5 of 3GPP TS 23.380 [7D].

NOTE 2: The P-CSCF can be completely unreachable, so it is up to UE implementation to detect the end of an ongoing session, e.g. using media plane inactivity detection. Services depending on signalling such as CW and MT calls will not work during this time.

## U.2.2.2 Session management procedures

The procedures for session management as described in 3GPP TS 24.501 [258] shall apply while the UE is connected to the IM CN subsystem.

## U.2.2.3 Mobility management procedures

The procedures for mobility management as described in 3GPP TS 24.501 [258] shall apply while the UE is connected to the IM CN subsystem.

## U.2.2.4 Cell selection and lack of coverage

The existing mechanisms and criteria for cell selection as described in 3GPP TS 38.304 [260] or 3GPP TS 36.304 [19B] shall apply while the UE is connected to the IM CN Subsystem.

## U.2.2.5 5GS QoS flow for media

### U.2.2.5.1 General requirements

NOTE 1: During establishment of a session, the UE establishes data streams(s) for media related to the session. Either the UE or the network can request for resource allocations for media, but the establishment and modification of the 5GS QoS flow is controlled by the network as described in 3GPP TS 24.501 [258].

If the resource allocation is initiated by the UE, the UE starts reserving resources whenever it has sufficient information about the media streams, and used codecs available as specified in 3GPP TS 24.501 [258].

NOTE 2: If the resource reservation requests are initiated by the network, then the establishment of 5GS QoS flow for media is initiated by the network after the P-CSCF has authorised the respective 5GS QoS flows and provided the QoS requirements to the PCF.

#### U.2.2.5.1A Activation or modification of QoS flows for media by the UE

If the UE is configured not to initiate resource allocation for media according to 3GPP TS 24.167 [8G], then the UE shall refrain from requesting additional 5GS QoS flow(s) for media until the UE considers that the network did not initiate resource allocation for the media.

#### U.2.2.5.1B Activation or modification of QoS flows for media by the network

If the UE receives an activation request from the network for a 5GS QoS flow for media which is associated with the 5GS QoS flow used for signalling, the UE shall correlate the media 5GS QoS flow with a currently ongoing SIP session establishment or SIP session modification.

If the UE receives a modification request from the network for a 5GS QoS flow that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) modify the related PDU session context in accordance with the request received from the network.

### U.2.2.5.1C Deactivation of a QoS flow for media

When a data stream for media related to a session is released, if the 5GS QoS flow transporting the data stream is no longer needed and allocation of the 5GS QoS flow was requested by the UE, then the UE releases the 5GS QoS flow.

NOTE: The 5GS QoS flow can be needed e.g. for other data streams of a session or for other applications in the UE.

### U.2.2.5.1D Default QoS flow usage restriction policy

The default QoS flow usage restriction policy consists of zero or more default QoS flow usage restriction policy parts.

The default QoS flow usage restriction policy part consists of a mandatory media type condition and an optional ICSI condition.

The default QoS flow usage restriction policy does not apply to UE detected emergency calls.

Sending media is restricted according to the default QoS flow usage restriction policy, if sending media is restricted according to at least one default QoS flow usage restriction policy part of the default QoS flow usage restriction policy.

Sending media is restricted according to the default QoS flow usage restriction policy part if:

- 1) the media is to be sent for a media stream negotiated in a session offered or established by SIP signalling;
- 2) the media stream is of a media type indicated in the media type condition of the QoS flow usage restriction policy part;
- 3) the following is true:
  - a) the default QoS flow usage restriction policy part does not have the ICSI condition; or
  - b) the session is offered or established by SIP signalling related to an IMS communication service identified in the ICSI condition of the default QoS flow usage restriction policy part; and
- 4) the media is to be sent via the default QoS flow of the PDN connection for SIP signalling.

The UE may support the default QoS flow usage restriction policy.

If the UE supports the default QoS flow usage restriction policy:

- 1) the UE shall not send media restricted according to the default QoS flow usage restriction policy; and
- 2) the UE may support being configured with the default QoS flow usage restriction policy using one or more of the following methods:
  - a) the `Default_QoS_Flow_usage_restriction_policy` node of the `EFIMSConfigData` file described in 3GPP TS 31.102 [15C];
  - b) the `Default_QoS_Flow_usage_restriction_policy` node of the `EFIMSConfigData` file described in 3GPP TS 31.103 [15B]; and
  - c) the `Default_QoS_Flow_usage_restriction_policy` node of 3GPP TS 24.167 [8G].

If the UE is configured with both the `Default_QoS_Flow_usage_restriction_policy` node of 3GPP TS 24.167 [8G] and the `Default_QoS_Flow_usage_restriction_policy` node of the `EFIMSConfigData` file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the `Default_QoS_Flow_usage_restriction_policy` node of the `EFIMSConfigData` file shall take precedence.

NOTE: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

### U.2.2.5.2 Special requirements applying to forked responses

NOTE 1: The procedures in this subclause only apply when the UE requests activation and modification of 5GS QoS flows for media. In the case where the network activates and modifies the 5GS QoS flows for media the network takes care of the handling of 5GS QoS flows in the case of forking.

Since the UE does not know that forking has occurred until a second, provisional response arrives, the UE requests resource allocation as required by the initial response received. If a subsequent provisional response is received, different alternative actions may be performed depending on the requirements in the SDP answer:

- 1) The resource requirements of the subsequent SDP can be accommodated by the existing resources requested. The UE performs no further resource requests.
- 2) The subsequent SDP introduces different QoS requirements or additional IP flows. The UE requests further resource allocation according to subclause U.2.2.5.1.
- 3) The subsequent SDP introduces one or more additional IP flows. The UE requests further resource allocation according to subclause U.2.2.5.1.

NOTE 2: When several forked responses are received, the resources requested by the UE are the "logical OR" of the resources indicated in the multiple responses to avoid allocation of unnecessary resources. The UE does not request more resources than proposed in the original INVITE request.

When a final answer is received for one of the early dialogs, the UE proceeds to set up the SIP session. The UE shall release all the unneeded IP-CAN resources. Therefore, upon the reception of the first final 200 (OK) response for the INVITE request (in addition to the procedures defined in RFC 3261 [26] subclause 13.2.2.4), the UE shall:

- 1) in case resources were established or modified as a consequence of the INVITE request and forked provisional responses that are not related to the accepted 200 (OK) response, send release request to release the unneeded resources.

### U.2.2.5.3 Unsuccessful situations

The UE can receive resource reservation related error codes in a PDU SESSION MODIFICATION REJECT as described in 3GPP TS 24.501 [258]. If the UE receives a resource reservation related error code, the UE shall either handle the resource reservation failure as described in subclause 6.1.1 or retransmit the message up to three times.

## U.2.2.6 Emergency service

### U.2.2.6.1 General

For the purposes of this document, an emergency PDU session is the equivalent of emergency bearers; i.e. the 5GS defines emergency bearers for the support of emergency calls. Emergency PDU session is defined for use in emergency calls in 5GS and core network support of emergency PDU session is indicated to the UE in NAS signalling. Where the UE recognises that a call request is an emergency call and the core network supports emergency PDU session, the UE shall use emergency PDU session for both signalling and media for emergency calls made using the IM CN subsystem.

Some jurisdictions allow emergency calls to be made when the UE does not contain an UICC, or where the credentials are not accepted. Additionally, where the UE is in state 5GMM-REGISTERED.LIMITED-SERVICE or 5GMM-REGISTERED.PLMN-SEARCH, a normal registration in 5GS has been attempted but it can also be assumed that a registration in the IM CN subsystem will also fail. In such cases, subject to the lower layers indicating that the network does support emergency bearer services in limited service state (see 3GPP TS 36.331 [19F] or 3GPP TS 38.331 [19G]), the procedures for emergency calls without registration can be applied, as defined in subclause 5.1.6.8.2. If the 5GS primary authentication procedure has already succeeded during the latest normal or emergency registration procedure in 5GS, the UE shall perform an initial emergency registration, as described in subclause 5.1.6.2 before attempting an emergency call as described in subclause 5.1.6.8.3.

NOTE 1: The UE can determine that 5GS primary authentication procedure has succeeded during the emergency registration procedure in 5GS when a non-null integrity protection algorithm (i.e. other than 5G-IA0 algorithm) is received in the NAS signalling SECURITY MODE COMMAND message.

To perform emergency registration, the UE shall request to establish an emergency PDU session as described in 3GPP TS 24.501 [258]. The procedures for PDU session establishment and P-CSCF discovery, as described in subclause U.2.2.1 of this specification apply accordingly.

In the present document, "EMS is Y" as described in 3GPP TS 23.167 [4B] refers to one of the following conditions:

- a) if the UE is in an NR cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMC is set to either "Emergency services supported in NR connected to 5GCN only" or "Emergency

services supported in NR connected to 5GCN and E-UTRA connected to 5GCN" as described in 3GPP TS 24.501 [258]; or

- b) if the UE is in an E-UTRA cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMC is set to either "Emergency services supported in E-UTRA connected to 5GCN only" or "Emergency services supported in NR connected to 5GCN and E-UTRA connected to 5GCN" as described in 3GPP TS 24.501 [258].

In the present document, "EMS is N" as described in 3GPP TS 23.167 [4B] refers to one of the following conditions:

- a) if the UE is in an NR cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMC is set to either "Emergency services not supported" or "Emergency services supported in E-UTRA connected to 5GCN only" as described in 3GPP TS 24.501 [258]; or
- b) if the UE is in an E-UTRA cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMC is set to either "Emergency services not supported" or "Emergency services supported in NR connected to 5GCN only" as described in 3GPP TS 24.501 [258].

In the present document, "ESFB is Y" as described in 3GPP TS 23.167 [4B] refers to one of the following conditions:

- a) if the UE is in an NR cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMF is set to either "Emergency service fallback supported in NR connected to 5GCN only" or "Emergency service fallback supported in NR connected to 5GCN and E-UTRA connected to 5GCN" as described in 3GPP TS 24.501 [258]; or
- b) if the UE is in an E-UTRA cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMF is set to either "Emergency service fallback supported in E-UTRA connected to 5GCN only" or "Emergency service fallback supported in NR connected to 5GCN and E-UTRA connected to 5GCN" as described in 3GPP TS 24.501 [258].

In the present document, "ESFB is N" as described in 3GPP TS 23.167 [4B] refers to one of the following conditions:

- a) if the UE is in an NR cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMF is set to either "Emergency service fallback not supported" or "Emergency service fallback supported in E-UTRA connected to 5GCN only" as described in 3GPP TS 24.501 [258]; or
- b) if the UE is in an E-UTRA cell connected to 5GCN, the network indicates in the REGISTRATION ACCEPT message that EMF is set to either "Emergency service fallback not supported" or "Emergency service fallback supported in NR connected to 5GCN only" as described in 3GPP TS 24.501 [258].

Emergency services fallback is defined to direct or redirect the UE towards either E-UTRA connected to 5GCN or EPS and support of emergency service fallback is indicated to the UE in NAS signalling.

In order to find out whether the UE is attached to the home PLMN or to the visited PLMN, the UE shall compare the MCC and MNC values derived from its IMSI with the MCC and MNC of the PLMN the UE is attached to. If the MCC and MNC of the PLMN the UE is attached to do not match with the MCC and MNC derived from the IMSI, then for the purpose of emergency calls in the IM CN subsystem the UE shall consider to be attached to a VPLMN.

NOTE 2: In this respect an equivalent HPLMN, as defined in 3GPP TS 23.122 [4C] will be considered as a visited network.

If the dialled number is equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]), then the UE shall recognize such a number as for an emergency call and:

- if the dialled number is equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform either procedures in the subclause U.2.2.6.1B or the procedures in subclause U.2.2.6.1A; and
- if the dialled number is not equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform procedures in the subclause U.2.2.6.1B.

If the dialled number is not equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]) and:

- if the dialled number is equal to an emergency number stored in the ME, in the USIM or in the Local Emergency Number List (as defined in 3GPP TS 24.008 [8]), then the UE shall recognize such a number as for an emergency call and performs the procedures in subclause U.2.2.6.1A.

NOTE 3: The UE verifies if a detected emergency number is still present in the Extended Local Emergency Number List after registering to a different PLMN. It is possible for the number to no longer be present in the Extended Local Emergency Number List if:

- the PLMN attached to relies on the Local Emergency Number List for deriving a URN; or
- the previously received Extended Emergency Number List Validity field indicated "Extended Local Emergency Numbers List is valid only in the PLMN from which this IE is received".

If the UE detected an emergency number, the UE subsequently performs a registration procedure or an emergency registration procedure with a different PLMN than the PLMN from which the UE received the last Extended Local Emergency Number List, the dialled number is not stored in the ME, in the USIM and in the Local Emergency Number List, and:

- the REGISTRATION ACCEPT message received from the different PLMN contains the Extended Local Emergency Number List and the emergency number is present in the updated Extended Local Emergency Number List then the UE uses the updated Extended Local Emergency Number List when it performs the procedures in subclause U.2.2.6.1B; and
- the REGISTRATION ACCEPT message received from the different PLMN contains no Extended Local Emergency Number List or the emergency number is no longer present in the updated Extended Local Emergency Number List then the UE shall attempt UE procedures for SIP that relate to emergency using emergency service URN "urn:service:sos".

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, if:

- the 380 (Alternate Service) response contains a Contact header field;
- the value of the Contact header field is a service URN; and
- the service URN has a top-level service type of "sos";

then the UE determines that "emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.3.1 if the 380 (Alternate Service) response does not contain a Contact header field with service URN that has a top-level service type of "sos", then the UE determines that "no emergency service information is included" as described 3GPP TS 23.167 [4B].

If the "emergency service information is included" as described 3GPP TS 23.167 [4B]:

- 1) if the URN in the Contact header field matches an emergency service URN in table U.2.2.6.1, then the type of emergency service is the value corresponding to the matching entry in table U.2.2.6.1; and
- 2) if the URN in the Contact header field does not match any emergency service URN in table U.2.2.6.1, then the type of emergency service is not identified.

NOTE 4: In bullet 2), the URN in the Contact header field either contains "no emergency subservice type" as described in 3GPP TS 23.167 [4B] triggering an emergency call, or contains an "emergency subservice type that does not map into an emergency service category for the CS domain" as described in 3GPP TS 23.167 [4B] triggering a normal call when the dialled number is available or triggering an emergency call when the dialled number is not available. The country specific URN is an example of a "emergency subservice type that does not map into an emergency service category for the CS domain".

When the emergency registration expires, the UE should disconnect the emergency PDU session.

Upon receiving a 3xx other than 380 (Alternative service), 4xx, 5xx or 6xx response to an INVITE request for a UE detectable emergency call, the UE shall perform domain selection as specified in 3GPP TS 23.167 [4B] annex H, to re-attempt the emergency call.

#### U.2.2.6.1A Type of emergency service derived from emergency service category value

The type of emergency service for an emergency number is derived from the settings of the emergency service category value (bits 1 to 5 of the emergency service category value as specified in subclause 10.5.4.33 of 3GPP TS 24.008 [8]).

Table U.2.2.6.1 below specifies mappings between a type of emergency service and an emergency service URN. The UE shall use the mapping to match an emergency service URN and a type of emergency service. If a dialled number is an emergency number but does not map to a type of emergency service the service URN shall be "urn:service:sos".

**Table U.2.2.6.1: Mapping between type of emergency service and emergency service URN**

| Type of emergency service | Emergency service URN     |
|---------------------------|---------------------------|
| Police                    | urn:service:sos.police    |
| Ambulance                 | urn:service:sos.ambulance |
| Fire Brigade              | urn:service:sos.fire      |
| Marine Guard              | urn:service:sos.marine    |
| Mountain Rescue           | urn:service:sos.mountain  |

NOTE 1: It is not possible for a UE to indicate more than one type of emergency service in an emergency service URN.

If an IP-CAN, capable of providing local emergency numbers, did not provide a local emergency number that matches the dialled number (see subclause 5.1.6.1) and multiple types of emergency service can be derived for a dialled number from the information configured on the UICC then:

- if the UE is in the HPLMN, the UE shall map any one of these types of emergency service to an emergency service URN as specified in table U.2.2.6.1; and
- if the UE is in the VPLMN, the UE shall select "urn:service:sos".

If an IP-CAN, capable of providing local emergency numbers, provided a local emergency number that matches the dialled number (see subclause 5.1.6.1), and:

- if the UE can derive one or more types of emergency service from the information received from the IP-CAN for the dialled number and the UE cannot derive types of emergency service from the information configured on the UICC for the dialled number; or
- if the UE is able to derive identical types of emergency service from both the information received from the IP-CAN for the dialled number and from the information configured on the UICC for the dialled number,

then the UE shall map any one of these emergency service types to an emergency service URN as specified in table U.2.2.6.1.

NOTE 2: How the UE resolves clashes where an emergency number is associated with one or more different types of emergency service configured in the USIM and in information received from the core network, is implementation dependent.

#### U.2.2.6.1B Type of emergency service derived from extended local emergency number list

The Extended Local Emergency Number List (defined in 3GPP TS 24.301 [8J]) can contain sub-services of the associated emergency service URN for the detected emergency number.

If:

- the length of sub-services field is greater than "0", the UE shall construct the emergency service URN using "urn:service:sos" followed by adding a dot followed by the content of the sub-services field; and
- the length of sub-services field is "0", the UE shall use the emergency service URN "urn:service:sos".

EXAMPLE 1: For a detected number, if the sub-service is "gas", then the UE constructs "urn:service:sos.gas" as the associated emergency service URN.

EXAMPLE 2: For a detected number, if no sub-service is provided, then the UE uses "urn:service:sos" as the associated emergency service URN.

### U.2.2.6.2 eCall type of emergency service

If the IP-CAN indicates the eCall support indication or the CS domain is not available to the UE, the UE can send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

If the IP-CAN does not indicate the eCall support indication and the CS domain is available to the UE, the UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

### U.2.2.6.3 Current location discovery during an emergency call

Void.

### U.2.2.6.4 Emergency services in single-registration mode

NOTE: This subclause covers only the case where the UE selects the IM CN subsystem in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B] and describes the IP-CAN specific procedure. It does not preclude the use of CS domain. When a CS system based on 3GPP TS 24.008 [8] is to be used, clause B.5 applies.

When the UE operates in single-registration mode as described in 3GPP TS 24.501 [258] and the UE recognises that a call request is an emergency call, if:

- 1) the IM CN subsystem is selected in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B]; and
- 2) the UE is currently registered to the 5GS services while the UE is in an NR cell connected to 5GCN;

then the following treatment is applied:

- 1) if the EMC indicates "Emergency services not supported":
  - a) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]), the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available;
  - b) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) and if:
    - i) the EMF is set to "Emergency services fallback supported in E-UTRA connected to 5GCN only" and the UE is capable of accessing 5GCN via E-UTRA, the UE shall either:
      - A) attempt to select an E-UTRA cell connected to 5GCN. If the UE finds a suitable E-UTRA cell connected to 5GCN, the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258] via E-UTRA connected to 5GCN. If the UE does not find a suitable E-UTRA cell connected to 5GCN or the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
      - B) attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
    - ii) the EMF is set to "Emergency services fallback not supported" or the UE is not capable of accessing 5GCN via E-UTRA, the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the

procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and

- c) if the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration;
- 2) if the EMC indicates "Emergency services supported in E-UTRA connected to 5GCN only":
- a) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]), the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available; and
  - b) if the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257] or the emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) and if:
    - i) the UE is capable of accessing 5GCN via E-UTRA, the UE shall attempt to select an E-UTRA cell connected to 5GCN. If the UE finds a suitable E-UTRA cell connected to 5GCN, the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258] via E-UTRA connected to 5GCN. If the UE does not find a suitable E-UTRA cell connected to 5GCN, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
    - ii) the UE is not capable of accessing 5GCN via E-UTRA, the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
- 3) if the EMC indicates "Emergency services supported in NR connected to 5GCN only" or "Emergency services supported in NR connected to 5GCN and E-UTRA connected to 5GCN", the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258].

When the UE operates in single-registration mode as described in 3GPP TS 24.501 [258] and the UE recognises that a call request is an emergency call, if:

- 1) the IM CN subsystem is selected in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B]; and
- 2) the UE is currently registered to the 5GS services while the UE is in an E-UTRA cell connected to 5GCN;

then the following treatment is applied:

- 1) if the EMC indicates "Emergency services not supported":
  - a) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]), the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available;
  - b) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) and if:
    - i) the EMF is set to "Emergency services fallback supported in NR connected to 5GCN only" and the UE is capable of accessing 5GCN via NR, the UE shall either:

- A) attempt to select an NR cell connected to 5GCN. If the UE finds a suitable NR cell connected to 5GCN, the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258] via NR connected to 5GCN. If the UE does not find a suitable NR cell connected to 5GCN or the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
  - B) attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
  - ii) the EMF is set to "Emergency services fallback not supported" or the UE is not capable of accessing 5GCN via NR, the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
  - c) if the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration;
- 2) if the EMC indicates "Emergency services supported in NR connected to 5GCN only":
- a) if the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257] and the emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]), the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available; and
  - b) if the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257] or the emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) and if:
    - i) the UE is capable of accessing 5GCN via NR, the UE shall attempt to select an NR cell connected to 5GCN. If the UE finds a suitable NR cell connected to 5GCN, the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258] via NR connected to 5GCN. If the UE does not find a suitable NR cell connected to 5GCN, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
    - ii) the UE is not capable of accessing 5GCN via NR, the UE shall disable the N1 mode capability for 3GPP access as specified in 3GPP TS 24.501 [257] and attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
- 3) if the EMC indicates "Emergency services supported in E-UTRA connected to 5GCN only" or "Emergency services supported in NR connected to 5GCN and E-UTRA connected to 5GCN", the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258].

### U.2.2.6.5 Emergency services in dual registration mode

NOTE 1: This subclause covers only the case where the UE selects the IM CN subsystem in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B] and describes the IP-CAN specific procedure. It does not preclude the use of CS domain. When a CS system based on 3GPP TS 24.008 [8] is to be used, clause B.5 applies.

When the UE operates in dual-registration mode as described in 3GPP TS 24.501 [258] and the UE recognises that a call request is an emergency call, if:

- 1) the IM CN subsystem is selected in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B]; and
- 2) the UE currently camps on an NR cell connected to 5GCN;

then the following treatment is applied:

- 1) if the EMC indicates "Emergency services not supported" and:
  - a) if the UE is attached for EPS services and the network provided the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
  - b) if the UE is not attached for EPS services, and:
    - i) if emergency services fallback is available (i.e. "ESFB is Y" as described in 3GPP TS 23.167 [4B]) and the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet ii) below assuming that the emergency services fallback is not available; or
    - ii) if emergency services fallback is not available (i.e. "ESFB is N" as described in 3GPP TS 23.167 [4B]) or the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration;
- 2) if the EMC indicates "Emergency services supported in E-UTRA connected to 5GCN only" and:
  - a) if the UE is attached for EPS services and:
    - i) if the network provided the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
    - ii) if the network provided the UE with the EMC BS set to "emergency bearer services in S1 mode not supported" as described in 3GPP TS 24.301 [8J] and the UE is capable of accessing 5GCN via E-UTRA, the UE shall be locally detached for EPS services and the UE shall attempt to select an E-UTRA cell connected to 5GCN. If the UE finds a suitable E-UTRA cell connected to 5GCN, the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258] via E-UTRA connected to 5GCN; or
  - b) if the UE is not attached for EPS services and:
    - i) if emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]) and the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet ii) below assuming that the emergency services fallback is not available; or
    - ii) if emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) or the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257], and:

- A) if the UE is capable of accessing 5GCN via E-UTRA, the UE shall attempt to select an E-UTRA cell connected to 5GCN. If the UE finds a suitable E-UTRA cell connected to 5GCN, the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258] via E-UTRA connected to 5GCN. If the UE does not find a suitable E-UTRA cell connected to 5GCN, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; or
  - B) if the UE is not capable of accessing 5GCN via E-UTRA, the UE shall attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
- 3) if the EMC indicates "Emergency services supported in NR connected to 5GCN only" or "Emergency services supported in NR connected to 5GCN and E-UTRA connected to 5GCN", and:
- a) if the UE is not attached for EPS services or the UE is attached for EPS services but the network provided the UE with the EMC BS set to "emergency bearer services in S1 mode not supported" as described in 3GPP TS 24.301 [8J], the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258]; or
  - b) if the UE is attached for EPS services and the network provided the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall either:
    - i) trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258]; or
    - ii) perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration.

NOTE 2: In the above case, the UE chooses between items i) and ii) based on UE implementation.

When the UE operates in dual-registration mode as described in 3GPP TS 24.501 [258] and the UE recognises that a call request is an emergency call, if:

- 1) the IM CN subsystem is selected in accordance with the conventions and rules specified in 3GPP TS 23.167 [4B]; and
- 2) the UE currently camps on an E-UTRA cell connected to 5GCN and the UE is not attached for EPS services;

then the following treatment is applied:

- 1) if the EMC indicates "Emergency services not supported" and:
  - a) if emergency services fallback is available (i.e. "ESFB is Y" as described in 3GPP TS 23.167 [4B]) and the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available; or
  - b) if emergency services fallback is not available (i.e. "ESFB is N" as described in 3GPP TS 23.167 [4B]) or the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC, the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
- 2) if the EMC indicates "Emergency services supported in NR connected to 5GCN only" and:
  - a) if emergency services fallback is available (i.e., "ESFB is Y" as described in 3GPP TS 23.167 [4B]) and the UE supports emergency services fallback as specified in 3GPP TS 23.501 [257], the UE shall attempt emergency services fallback as specified in 3GPP TS 24.501 [258]. If the UE receives from the lower layers an indication that the emergency services fallback attempt failed, the UE may behave as described in bullet b) below assuming that the emergency services fallback is not available; or

- b) if emergency services fallback is not available (i.e., "ESFB is N" as described in 3GPP TS 23.167 [4B]) or the UE does not support emergency services fallback as specified in 3GPP TS 23.501 [257] and:
  - i) if the UE is capable of accessing 5GCN via NR, the UE shall attempt to select an NR cell connected to 5GCN. If the UE finds a suitable NR cell connected to 5GCN, the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258] via NR connected to 5GCN. If the UE cannot find a suitable NR cell connected to 5GCN, the UE may attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
  - ii) if the UE is not capable of accessing 5GCN via NR, the UE shall attempt to select an E-UTRA cell connected to EPC. If the UE finds a suitable E-UTRA cell connected to EPC and the network provides the UE with the EMC BS set to "emergency bearer services in S1 mode supported" as described in 3GPP TS 24.301 [8J], the UE shall perform the procedures as described in subclause L.2.2.6 to activate an EPS bearer context to perform emergency registration; and
- 3) if the EMC indicates "Emergency services supported in E-UTRA connected to 5GCN only" or "Emergency services supported in NR connected to 5GCN and E-UTRA connected to 5GCN", the UE shall trigger establishment of an emergency PDU session as specified in 3GPP TS 24.501 [258].

If the UE operating in dual-registration mode and camping on an E-UTRA cell connected to 5GCN, is also attached for EPS service, the domain selection is out of the scope of the specification.

---

## U.2A Usage of SDP

### U.2A.0 General

No additional procedures defined.

### U.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

If, due to the activation of 5GS QoS flow from the network the related SDP media description needs to be changed, the UE shall update the related SDP information by sending a new SDP offer within a SIP request, which is sent over the existing SIP dialog.

If the UE receives a modification request from the network for a 5GS QoS flow that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) if, due to the modification of the 5GS QoS flow, the related SDP media description need to be changed, update the related SDP information by sending a new SDP offer within a SIP request, that is sent over the existing SIP dialog, and respond to the 5GS QoS flow modification request.

NOTE: The UE can decide to indicate additional media streams as well as additional or different codecs in the SDP offer than those used in the already ongoing session.

### U.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

If the UE receives an SDP offer where the SDP offer includes all media streams for which the originating side indicated its local preconditions as met, if the precondition mechanism is supported by the terminating UE and the IP-CAN performs network-initiated resource reservation for the terminating UE and the available resources are not sufficient for

the received offer, the terminating UE shall indicate its local preconditions and provide the SDP answer to the originating side without waiting for resource reservation.

## U.2A.3 Emergency service

NOTE: When establishing an emergency session or when modifying an emergency session, the IMSVoPS indicator does not influence handling of SDP offer and SDP answer.

---

# U.3 Application usage of SIP

## U.3.1 Procedures at the UE

### U.3.1.0 Registration and authentication

The UE shall perform reregistration of a previously registered public user identity bound to any one of its contact addresses when changing to an IP-CAN for which usage is specified in annex R or annex W. The reregistration is performed using the new IP-CAN.

NOTE 1: This document does not specify how the UE detects that the used IP-CAN has changed. The information that is forcing the reregistration is also used to generate the content for the P-Access-Network-Info header field.

NOTE 2: The UE will send the reregistration irrespective of whether it has a SIP dialog or not.

If the UE supports the 3GPP PS data off, then the UE shall in all REGISTER requests include the "+g.3gpp.ps-data-off" header field parameter defined in subclause 7.9.8 set to a value indicating the 3GPP PS data off status.

When the UE sends a REGISTER request, if the 3GPP PS data off status is "active", then the UE shall only include media feature tags associated with services that are 3GPP PS data off exempt services in the g.3gpp.icsi-ref media feature tag, as defined in subclause 7.9.2 and RFC 3840 [62], for the IMS communication services it intends to use.

If the UE is registered, and the 3GPP PS data off status is changed, then the UE shall perform a reregistration of the previously registered public user identity.

A UE supporting ANBR as specified in 3GPP TS 26.114 [9B] shall also support RAN-assisted codec adaptation as specified in 3GPP TS 38.300 [270] and 3GPP TS 38.321 [271].

If the UE supports ANBR, upon receiving a 200 (OK) response to the REGISTER request and if the 200 (OK) response contains a Feature-Caps header field with the g.3gpp.anbr feature-capability indicator the UE shall assume that the Network supports RAN-assisted codec adaptation as specified in 3GPP TS 38.300 [270] and 3GPP TS 38.321 [271]. The UE is allowed to include the SDP 'anbr' attribute during session establishment as specified in 3GPP TS 26.114 [9B].

#### U.3.1.0A IMS\_Registration\_handling policy

The IMS\_Registration\_handling policy indicates whether the UE deregisters from IMS after a configured amount of time after receiving an indication that the IMS Voice over PS Session is not supported.

The UE may support the IMS\_Registration\_handling policy.

If the UE supports the IMS\_Registration\_handling policy, the UE may support being configured with the IMS\_Registration\_handling policy using one or more of the following methods:

- a) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G].

If the UE is configured with both the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G] and the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the IMS\_Registration\_Policy node of the EF<sub>IMSConfigData</sub> file shall take precedence.

NOTE 1: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

If the UE is registered with IMS and the IMSVoPS indicator, provided by the lower layers (see 3GPP TS 24.501 [258]), indicates voice is not supported, the UE shall:

- A) if the Stay\_Registered\_When\_VoPS\_Not\_Supported leaf indicates requirement to stay registered, the UE needs not to deregister and maintains the registration as required for IMS services; or

NOTE 2: The UE will periodically refresh the registration when needed.

- B) if the Stay\_Registered\_When\_VoPS\_Not\_Supported leaf indicates requirement to deregister and the Deregistration\_Timer leaf used to configure the NoVoPS-dereg timer defined in table 7.8.1 contains a timer value for the time to wait before deregistering from IMS, start a timer with the value indicated in the policy and:

- a) if the timer expires before the UE receives an indication from the lower layers that IMS voice is supported:
- 1) if there is no ongoing IMS session, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6; or
  - 2) if there is ongoing IMS session, and
    - i) if the UE does not receive indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6 as soon as the ongoing IMS based service is terminated; or
    - ii) if the UE receives indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, cancel the timer; or

NOTE 3: How the UE selects reregistration or deregistration is implementation dependent (e.g., SMS service)

- b) if the UE receives an indication from the lower layers that IMS voice is supported before the timer expires, cancel the timer.

If the IMS\_Registration\_handling policy is not configured, the UE behaviour is implementation specific.

### U.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

NOTE: If the P-Access-Network-Info header field includes radio cell identity, the P-Access-Network-Info header field populated by the UE that supports Multi-RAT Dual Connectivity with the 5GCN as described in 3GPP TS 37.340 [264] will contain the information about the radio cell identity of the Master RAN node that is serving the UE.

#### U.3.1.1A Cellular-Network-Info header field

Not applicable.

#### U.3.1.2 Availability for calls

This subclause documents the minimal requirements for being available for voice communication services when using 5GS.

A UE shall perform an initial registration as specified in subclause 5.1.1.2 using a QoS flow for SIP signalling (see annex U.2.2.1), if all the following conditions are met:

- 1) if the UE is operating in the "voice centric" way;
- 2) if the UE is capable of receiving any (but not necessarily all) of the media types which the CS domain supports, such that the media type can also be used when accessing the IM CN subsystem using:
  - a) the 5GS IP-CAN via NR;
  - b) the 5GS IP-CAN via E-UTRA; or

NOTE 1: The use of 5GS IP-CAN via E-UTRA can also be the result of an inter-RAT fallback during setup of the IMS voice call. This can occur, for example, when a UE not supporting the media type in 5GS IP-CAN via NR initiates an IMS voice call in 5GS IP-CAN via NR.

- c) the EPS IP-CAN;

NOTE 2: EPS can be used as IP-CAN as the result of an EPS fallback during setup of the IMS voice call. This can occur, for example, when a UE not supporting the media type in 5GS IP-CAN via NR initiates an IMS voice call in 5GS IP-CAN via NR, or when a UE not supporting the media type in 5GS IP-CAN via E-UTRA initiates an IMS voice call in 5GS IP-CAN via E-UTRA.

- 3) if:
  - a) the media type of item 2 is an "audio" media type;
  - b) the UE supports codecs suitable for (conversational) speech; and
  - c) the "audio" media type is not restricted from inclusion in an SDP message according to the media type restriction policy as specified in subclause 6.1.1;and one of the following is true:
  - a) 3GPP PS data off status is "inactive";
  - b) 3GPP PS data off status is "active", the UE is in the HPLMN or the EHPLMN, and MMTEL voice is a 3GPP PS data off exempt service; or
  - c) 3GPP PS data off status is "active", the UE is in the VPLMN, the UE is configured with an indication that MMTEL voice is a 3GPP PS data off exempt service in a VPLMN, and MMTEL voice is a 3GPP PS data off roaming exempt service;
- 4) if the UE determines that its contact has not been bound to a public user identity using the IP-CAN, such that the contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to the media of item 2 and item 3;
- 5) if the IMSVoPS indicator, provided by the lower layers indicates voice is supported;
- 6) if the procedures to perform the initial registration are enabled (see 3GPP TS 24.305 [8T]); and
- 7) if the PDU session used for IMS is:
  - a) available; or
  - b) not available, and the UE is allowed to send a PDU SESSION ESTABLISHMENT REQUEST message to establish a PDU session with 5GS QoS flow that is needed for performing the initial registration as described in U.2.2.1.

NOTE 3: Regardless of any of the above conditions, a UE might attempt to register with the IM CN subsystem at any time.

EXAMPLE: As an example of the note, a UE configured to preferably attempt to use the 5GS to access IM CN subsystem can perform an initial registration as specified in subclause 5.1.1.2, if the conditions in items 2, 3, 4, 5, 6 and 7 in this subclause, evaluate to true.

The UE indicates to the non-access stratum the status of being available for voice over PS when:

- I) the UE is capable of receiving any (but not necessarily all) of the media types which the CS domain supports, such that the media type can also be used when accessing the IM CN subsystem using:

- a) the 5GS IP-CAN via NR;b) the 5GS IP-CAN via E-UTRA; or

NOTE 4: The use of 5GS IP-CAN via E-UTRA can also be the result of an inter-RAT fallback during setup of the IMS voice call. This can occur, for example, when a UE not supporting the media type in 5GS IP-CAN via NR initiates an IMS voice call in 5GS IP-CAN via NR.

- c) the EPS IP-CAN;

NOTE 5: EPS can be used as IP-CAN as the result of an EPS fallback during setup of the IMS voice call. This can occur, for example, when a UE not supporting the media type in 5GS IP-CAN via NR initiates an IMS voice call in 5GS IP-CAN via NR, or when a UE not supporting the media type in 5GS IP-CAN via E-UTRA initiates an IMS voice call in 5GS IP-CAN via E-UTRA.

II) if the media type of item I is an "audio" media type, the UE supports codecs suitable for (conversational) speech, the "audio" media type is not restricted from inclusion in an SDP message according to the media type restriction policy as specified in subclause 6.1.1; and:

- a) 3GPP PS data off status is "inactive";
- b) 3GPP PS data off status is "active", the UE is in the HPLMN or the EHPLMN, and MMTEL voice is a 3GPP PS data off exempt service; or
- c) 3GPP PS data off status is "active", the UE is in the VPLMN, the UE is configured with an indication that MMTEL voice is a 3GPP PS data off exempt service in a VPLMN, and MMTEL voice is a 3GPP PS data off roaming exempt service; and

III) the UE determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media.

The UE indicates to the non-access stratum the status of being not available for voice over PS when:

- I) in response to receiving the IMSVoPS indicator indicating voice is supported, the UE:
- initiated an initial registration as specified in subclause 5.1.1.2, received a final response to the REGISTER request sent, but the conditions for indicating the status of being available for voice over PS are not met; or
  - did not initiate an initial registration as specified in subclause 5.1.1.2 and, these conditions for indicating the status of being available for voice over PS are not met; or
- II) the conditions for indicating the status of being available for voice over PS are no longer met.

NOTE 6: The status of being not available for voice over PS is used for domain selection for UE originating sessions / calls specified in 3GPP TS 23.501 [257] subclause 5.16.3.5.

### U.3.1.2A Availability for SMS

The UE determines that the UE is able to use SMS using IMS if the UE:

- I) is capable of using the MIME type "application/vnd.3gpp.sms" (see 3GPP TS 24.341 [8L]), such that the MIME type can also be used when accessing the IM CN subsystem using the current IP-CAN;
- II) supports the role of an SM-over-IP sender (see 3GPP TS 24.341 [8L]);
- IIA) determines the PDU session used for IMS exists;
- III) determines a contact has been bound to a public user identity using the IP-CAN, such that this contact is expected to be used for the delivery of incoming requests in the IM CN subsystem relating to such media; and
- IV) the UE does not determine that SMS over IP is restricted in 3GPP TS 24.341 [8L] subclause 5.2.1.3; and
- V) the 3GPP PS data off status is:
- "inactive";
  - "active", the UE is in the HPLMN or the EHPLMN, and SMS over IMS is a 3GPP PS data off exempt service; or

- "active", the UE is in the VPLMN, the UE is configured with an indication that SMS over IMS is a 3GPP PS data off roaming exempt service in a VPLMN, and SMS over IMS is a 3GPP PS data off roaming exempt service.

When above criteria are not met, the UE determines that SMS using IMS is unavailable.

NOTE: The status that SMS using IMS is unavailable is used for domain selection for UE originating SMS specified in 3GPP TS 23.501 [257] subclause 5.16.3.8.

### U.3.1.3 Authorization header field

Void.

### U.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Upon receiving an INVITE request not including the "precondition" option-tag in the Supported header field and not including the "precondition" option-tag in the Require header field, and the IP-CAN performs network-initiated resource reservation for the UE, the UE:

- 1) if the INVITE request contains an SDP offer and the local resources required at the terminating UE for the received SDP offer are not available:
  - a) shall not alert the user; and
  - b) shall send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. If the INVITE request includes a Supported header field indicating support of reliable provisional responses, the UE shall send the 183 (Session Progress) response reliably. In the 183 (Session Progress) response, the UE shall include an SDP answer; and
- 2) if the INVITE request does not contain an SDP offer and the INVITE request includes a Supported header field indicating support of reliable provisional responses:
  - a) shall generate an SDP offer;
  - b) if the local resources required at the terminating UE for the generated SDP offer are not available:
    - A) shall not alert the user; and
    - B) shall reliably send 183 (Session Progress) response to the INVITE request without waiting for resource reservation and without alerting the user. In the 183 (Session Progress) response, the UE shall include the generated SDP offer.

Upon successful reservation of local resources, if the precondition mechanism is not used by the terminating UE, the UE can send 180 (Ringing) response to the INVITE request and can alert the user.

### U.3.1.5 3GPP PS data off

If the 3GPP PS data off status is "active" the UE shall only send initial requests that:

- 1) are associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE 1: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are associated with an emergency service; or
- 3) are associated with 3GPP PS data off exempt services configured in the UE using one or more of the following methods:

- the non\_3GPP\_ICSIIs\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
- the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the VPLMN;
- the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
- the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the 3GPP PS data off status changes from "inactive" to "active" the UE shall release all dialogs that

- 1) are not associated with a 3GPP IMS service which enforces 3GPP PS data off;

NOTE 2: These services are specified in 3GPP TS 22.011 [1C], and enforcement of 3GPP PS data off is described in the respective service specifications.

- 2) are not associated with an emergency service; and

- 3) are not associated with 3GPP data off exempt services configured in the UE using one or more of the following methods:

- the non\_3GPP\_ICSIIs\_exempt node specified in 3GPP TS 24.167 [8G], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node specified in 3GPP TS 24.167 [8G] is not configured;
- the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN;
- the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the HPLMN or the EHPLMN, or if the UE is in the VPLMN and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] is not configured; or
- the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], if the UE is in the VPLMN.

If the UE is configured with both the non\_3GPP\_ICSIIs\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

If the UE is configured with both the non\_3GPP\_ICSIIs\_roaming\_exempt node of 3GPP TS 24.167 [8G] and the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C], then the non\_3GPP\_ICSIIs\_roaming\_exempt node in the EF<sub>3GPPPSDATAOFFservicelist</sub> file described in 3GPP TS 31.102 [15C] shall take precedence.

### U.3.1.6 RLOS

Not applicable.

### U.3.1.7 SIP handling at the originating UE when redirecting the UE from NG-RAN to E-UTRAN fails

When a failure occurs in the process of redirecting the UE from NG-RAN to E-UTRAN and the UE is aware of the failure, the UE shall send out a CANCEL request to cancel the INVITE request that includes a Reason header field with a protocol value set to "RELEASE\_CAUSE" and a "cause" header field parameter with the value of "7" as specified in subclause 7.2A.18.11.2.

### U.3.1.8 Unified Access Control

The following information is provided to the non-access stratum:

- MO--IMS-registration-related-signalling-started; and
- MO-IMS-registration-related-signalling-ended;

Prior to sending a REGISTER request which is not for emergency registration, the UE sends the MO-IMS-registration-related-signalling-started to the non-access stratum and

- a) if the barring result is "not-barred", continues with registration procedure as described in subclause 5.1.1; and
- b) if the barring result is "barred", aborts the registration procedure;

When the UE needs to send SUBSCRIBE request for the reg event package, then the UE sends the MO-IMS-registration-related-signalling-started to the non-access stratum before sending SUBSCRIBE request and

- a) if the barring result is "not-barred", continues with subscribe procedure as described in subclause 5.1.1.3; and
- b) if the barring result is "barred", aborts the subscribe procedure;

When a procedure for MO IMS registration related signalling ends, i.e.

- a final response to the REGISTER request which is not for emergency registration is received;
- a final response to the SUBSCRIBE request for the reg event package is received;
- timer F expires at the UE; or
- a fatal transport error for sending the REGISTER request or the SUBSCRIBE request is reported by the transport layer, as described in IETF RFC 3261 [26];

the UE sends the MO-IMS-registration-related-signalling-ended to the non-access stratum.

### U.3.1.9 Abnormal cases

Upon sending MO-IMS-registration-related-signalling-started indication to the non-access stratum as described in subclause U.3.1.8, if:

- a) the UE receives, from the lower layers, a notification that the service request
  - 1) was not accepted due to congestion; or
  - 2) resulted in starting timer T3525 (see 3GPP TS 24.501 [258]); and
- b) a procedure for MO IMS registration related signalling has not ended;

then:

- a) the UE shall abort the procedure for MO-IMS-registration-related-signalling and send MO-IMS-registration-related-signalling-ended indication to the non-access stratum; and
- b) if an alternative radio access network is available, the UE may attempt the procedure for MO-IMS-registration-related signalling on the alternative radio access network.

## U.3.2 Procedures at the P-CSCF

### U.3.2.0 Registration and authentication

Void.

#### U.3.2.1 Determining network to which the originating user is attached

If the P-CSCF is configured to handle emergency requests, in order to determine from which network the request was originated the P-CSCF shall check the MCC and MNC fields received:

- during the registration procedure from the Rx interface as defined in 3GPP TS 29.214 [13D] (e.g. used for deployments without IMS-level roaming interfaces where the P-CSCF is located in the home network); or
- from the P-Access-Network-Info header field.

NOTE: The above check can be against more than one MNC code stored in the P-CSCF.

#### U.3.2.2 Location information handling

Void.

#### U.3.2.3 Prohibited usage of PDU session for emergency services

If the P-CSCF detects that a UE uses a PDU session for emergency services for a non-emergency REGISTER request, the P-CSCF shall reject that request by a 403 (Forbidden) response.

NOTE: By assigning specific IP address ranges for a PDU session for emergency bearer services and configuring those ranges in P-CSCF, the P-CSCF can detect based on the registered Contact address if UE uses an emergency PDU session for initial registration.

#### U.3.2.4 Support for paging policy differentiation

The P-CSCF may support paging policy differentiation by marking packet(s) to be sent towards the UE related to that IMS capability. A specific DSCP (IPv4) value and/or a specific Traffic Class (IPv6) value are assigned by local configuration in the P-CSCF.

If local policy requires to provide such marking, the P-CSCF shall identify terminating requests which:

- a) contain SDP with an "audio" media line and which are related to a IMS multimedia telephony service session specified in 3GPP TS 24.173 [8H]; or
- b) do not contain an SDP offer but some indication, e.g. a feature capability indicator, indicates that an "audio" media line that would meet network policy for such differentiation, could form part of the subsequent SDP offer.

NOTE 1: Precise details of such indications, if any, are subject to operator policy. Alternatively the operator policy can be to not preferentially page requests without an SDP offer.

For such identified requests:

- a) where an unreliable transport mechanism is used as the transport protocol for SIP, the P-CSCF shall mark packets containing an INVITE request; and
- b) if a reliable transport mechanism is used as the transport protocol for SIP:
  - 1) if a new reliable transport connection needs to be established, the P-CSCF shall turn on the marking of packets within the reliable transport connection in advance of sending an INVITE request; and
  - 2) if there is an existing reliable transport connection, the P-CSCF may turn on the marking of packets within the reliable transport connection in advance of sending an INVITE request.

In both these cases for a reliable transport connection, the P-CSCF shall turn off the marking of packets within the reliable transport connection at an appropriate time.

### U.3.2.5 Void

### U.3.2.6 Resource sharing

This feature is not supported in this release.

### U.3.2.7 Priority sharing

This feature is not supported in this release.

### U.3.2.8 RLOS

Not applicable.

### U.3.2.9 Support of ANBR and RAN-assisted codec adaptation

If the network supports ANBR as specified in 3GPP TS 26.114 [9B] and RAN-assisted codec adaptation as specified in 3GPP TS 38.300 [270] and 3GPP TS 38.321 [271], then the P-CSCF might be configured to indicate ANBR support.

If the P-CSCF is configured to indicate ANBR support, when the P-CSCF receives the 200 (OK) response to the REGISTER request the P-CSCF shall include the "g.3gpp.anbr" feature-capability indicator in the Feature-Caps header field of the 200 (OK) response to the REGISTER request.

## U.3.3 Procedures at the S-CSCF

### U.3.3.1 Notification of AS about registration status

Not applicable.

### U.3.3.2 RLOS

Not applicable.

---

## U.4 3GPP specific encoding for SIP header field extensions

### U.4.1 Void

---

## U.5 Use of circuit-switched domain

There is no CS domain in this access technology.

---

# Annex V (normative): HTTP Profiling

## V.1 Scope

The present annex defines the HTTP messages and data types sent over reference points specified in the present document.

---

## V.2 Ms reference point

### V.2.1 General

For the Ms reference point HTTP 1.1 as specified in RFC 2616 [196] shall be used.

The Ms reference point is used to request signing of an Identity header field or request verification of a signed identity in an Identity header field.

HTTP POST method is used for the verification request.

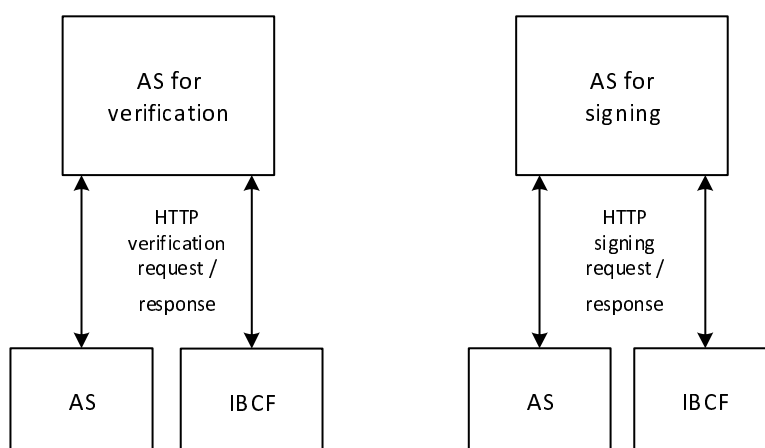

HTTP 200 (OK) is used when the server has successfully processed the verification request.

HTTP POST method is used for the signing request.

HTTP 200 (OK) is used when the server has successfully processed the signing request.

HTTP POST method is used for the diversion signing request.

HTTP 200 (OK) is used when the server has successfully processed the diversion signing request.

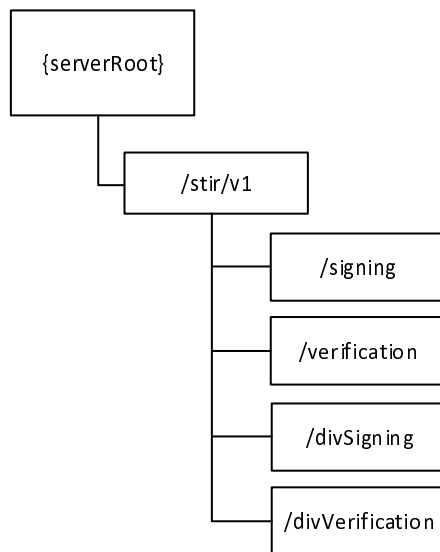

**Figure V.2.1-1: Usage of the Ms reference point**

### V.2.2 Resource structure

API resources are defined with respect to a "server root". The server root is a URI:

- {hostname}:{port}/{RoutingPath},

The resource URI structure is:

**Figure V.2.2-1: Resource structure for the resource exposed over the Ms reference point**

NOTE: v1 is the version number of the API.

**Table V.2.2-1: Variables for the server root**

| Variable    | Description                           | Presence |
|-------------|---------------------------------------|----------|
| hostname    | Host name used to reach the resource. | M        |
| port        | Port where the resource is reached    | M        |
| RoutingPath | Path identifying the resource         | M        |

## V.2.3 Request requirements

### V.2.3.1 General

### V.2.3.2 Request header requirements

Table V.2.3.2-1 lists request header field requirements.

**Table V.2.3.2-1: Header fields included in the requests**

| Header field name | Description  | Presence |
|-------------------|--|----------|
| Content-Type      | Describes the format of the request body. Shall be set to "application/json"                       | M        |
| Accept            | Describes the supported format of the response body. Shall be set to "application/json" if present | O        |

## V.2.4 Response requirements

### V.2.4.1 General

### V.2.4.2 Response header requirements

**Table V.2.4.2-1: Header fields included in the responses**

| Header field name | Description   | Presence |
|-------------------|---|----------|
| Content-Type      | Describes the format of the response body. Shall be set to "application/json" | M        |

### V.2.4.3 Error response requirements

#### V.2.4.3.1 General

If the server cannot process the request, the server provides an HTTP error response. The error response contains JSON object specifying the error type.

The server provides a service error when the server is unable to process the request.

The server provides a policy error when the server is able to process the request, but not able to complete the service execution due to a policy restriction.

#### V.2.4.3.2 Service errors

**Table V.2.4.3.2-1: Service failure descriptions**

| Exception ID | Exception text  | HTTP status code | Exception variables | Description  |
|--------------|---|------------------|---------------------|--|
| -            | Error: Missing request body.                          | 400              | -                   | The request could not be processed due to missing request body.                            |
| -            | Error: Missing mandatory parameter.                   | 400              | -                   | The request could not be processed due to missing parameters.                              |
| -            | Error: Requested response body type is not supported. | 406              | -                   | The request could not be processed due to a not supported message body format.             |
| -            | Error: Requested resource not found.                  | 404              | -                   | The request could not be processed due to no resource available related to the Request-URI |
| -            | Error: Unsupported request body type.                 | 415              | -                   | The request could not be processed due to not supported message body.                      |
| -            | Error: Invalid parameter value.                       | 400              | -                   | The request could not be processed due to invalid parameter value.                         |
| -            | Error: Failed to parse message body.                  | 400              | -                   | The request could not be processed due to failure to parse the message body.               |
| -            | Error: Missing mandatory Content-Length headers       | 411              | -                   | The request could not be processed due to a missing Content-Length header.                 |

### V.2.4.3.3 Policy errors

**Table V.2.4.3.3-1: Policy failure descriptions**

| Exception ID | Exception text         | HTTP status code | Exception variables | Description   |
|--------------|------------------------|------------------|---------------------|---|
| -            | Method not allowed     | 405              | -                   | The resource was invoked with unsupported operation |
| -            | Internal server error. | 500              | -                   | The request failed due to internal error            |

## V.2.5 signing

### V.2.5.1 General

To get an asserted identity signed the client sends an HTTP POST request towards the signing server containing a PASSporT SHAKEN object, specified in RFC 8588 [261]. The received signingResponse contains for successful requests the signed Identity header field value in a JSON object. Unsuccessful requests are responded with an HTTP 4xx or 5xx response.

### V.2.5.2 Data types

Table V.2.5.2-1 specifies the data types included in the signing request. The signing request contains either the claims included in a PASSporT SHAKEN JSON Web Token, specified in RFC 8588 [261], or a PASSporT div JSON Web Token specified in RFC 8946 [265].

**Table V.2.5.2-1: Data types for the signingRequest**

| Parameter | Type; Value   | Presence | Description   |
|-----------|---|----------|---|
| attest    | string; "A", "B" or "C"   | O        | Identifying the relation between the service provider attesting the identity and the subscriber. Specified in RFC 8588 [261].   |
| dest      | array of identity claim JSON objects representing destination identities; tn or uri | M        | Identifying the called user taken from the To header field for a PASSporT SHAKEN Token, and from the Request-URI for a PASSporT div Token. Specified in RFC 8225 [262]. |
| div       | identity claim JSON object, tn or uri. A hi element should be included.             | O        | Identifying the diverting user, taken from the corresponding Identity header field as specified in RFC 8946 [265].  |
| iat       | integer; time and date of issuance of the PASSporT token                            | M        | Time since 1 January 1970 in Numeric Date format as specified in RFC 7519 [235].  |
| orig      | identity claim JSON object; tn or uri   | M        | Identifying the calling user. Specified in RFC 8225 [262].  |
| origid    | String; UUID  | O        | Specified in RFC 8588 [261]   |

Table V.2.5.2-2 further specifies the data types contained in the signing request parameters.

**Table V.2.5.2-2: Data types for the signingRequest parameters**

| Parameter | Type; Value   | Presence | Description  |
|-----------|---|----------|--|
| hi        | string. An "index" header field parameter as specified in RFC 7044 [66]                                 | O        | The "index" header field parameter is included in the entry identifying the diverting user in the History-Info header field. |
| tn        | string; allowed characters as for local-number-digits and global-number-digits defined in RFC 3966 [22] | M        | The number needs to be canonicalized by the server following the procedure in RFC 8224 section 8.3.                          |
| uri       | string; A SIP URI as specified in RFC 3261 [26] following the generic guidelines in RFC [3986].         | O        | Used if the "orig" or "dest" is given in a SIP URI.  |

Table V.2.5.2-3 specifies the data types included in the signing response.

**Table V.2.5.2-3: Data types for the signingResponse**

| Parameter      | Type; Value  | Presence | Description                |
|----------------|--|----------|----------------------------|
| identityHeader | string; Identity header field value as specified in RFC 8224 [252] | M        | This string cannot be NULL |

## V.2.6 verification

### V.2.6.1 General

To get a received identity verified the client sends an HTTP POST request towards the verifications server containing a PASSporT object, including an identity claim with the contents of the received Identity header field signing the originating identity and optionally all the Identity header fields signing diverting identities. The received verificationResponse contains the outcome of the verification in a verstat claim with values as specified for the verstat tel URI parameter in subclause 7.2A.20. Unsuccessful requests are responded with an HTTP 4xx or 5xx response.

### V.2.6.2 Data types

Table V.2.6.2-1 specifies the data types included in the verification request.

**Table V.2.6.2-1: Data types for the verificationRequest**

| Parameter       | Type; Value   | Presence | Description  |
|-----------------|---|----------|--|
| identityHeader  | string; Identity header field value for the originating identity as specified in RFC 8224 [252]   | M        | This string cannot be NULL   |
| IdentityHeaders | array of string; Identity header field values as specified in RFC 8224 [252]. One identityHeader claim per received Identity header field is sent | O        | Identity headers containing the div claims to be verified.   |
| to              | String; identity claim JSON object; tn or uri   | M        | The destination identity taken from the To header field. Used when no div claim is included.               |
| dest            | string; identity claim JSON object; tn or uri   | O        | The destination identity taken from the R-URI in the incoming request. Used when div claim is included.    |
| time            | integer; Numeric date format defined in RFC 7519 [235]  | M        | Time based on the Date header field in the incoming request.   |
| from            | string; identity claim JSON object; tn or uri   | M        | The asserted identity, taken from the P-Asserted-Identity or the From header field of the incoming request |

Table V.2.6.2-2 specifies the data types included in the verification response.

**Table V.2.6.2-2: Data types for the verificationResponse**

| Parameter    | Type; Value   | Presence | Description  |
|--------------|---|----------|--|
| divResult    | array of one or more [div, verstatValue] tuples     | O        | Parameter informing of the result of the verification of diverting identities. For each verified identity the verstat parameter is added to the verified identity. |
| verstatValue | string; set to a value defined in table 7.2A.20.3-1 | M        | Parameter informing of the result of the verification of originating identity. To be used in the verstat parameter added to the verified identity.                 |

---

# Annex W (normative): IP-Connectivity Access Network specific concepts when using the 5GCN via WLAN to access IM CN subsystem

## W.1 Scope

The present annex defines IP-CAN specific requirements for a call control protocol for use in the IM CN subsystem based on the Session Initiation Protocol (SIP), and the associated Session Description Protocol (SDP), where the IP-CAN is the 5GCN via Wireless Local Access Network (WLAN).

---

## W.2 IP-CAN aspects when connected to the IM CN subsystem

### W.2.1 Introduction

A UE accessing the IM CN subsystem, and the IM CN subsystem itself, utilise the services provided by the 5GCN and the WLAN to provide packet-mode communication between the UE and the IM CN subsystem.

Requirements for the UE on the use of these packet-mode services are specified in this clause.

### W.2.2 Procedures at the UE

#### W.2.2.1 Establishment of IP-CAN bearer and P-CSCF discovery

NOTE: The UE performs access network discovery and selection procedures as specified in 3GPP TS 24.502 [263] and executes access authentication signalling as described in 3GPP TS 24.502 [263] prior to perform the procedure to obtain a local IP address;

The UE handles an IP-CAN bearer for SIP signalling as follows:

- 1) the UE shall obtain a local IP address;
- 2) the UE shall establish an IKEv2 security association and an IPsec ESP security association as described in 3GPP TS 24.502 [263]; and
- 3) the IKEv2 security association and the IPsec ESP security association (tunnel) shall remain active throughout the period the UE is connected to the IM CN subsystem, i.e. from the initial registration and at least until the deregistration; and

In addition the procedures specified in Annex U.2.2.1 apply

#### W.2.2.1A Modification of an IP-CAN used for SIP signalling

The procedures specified in Annex U.2.2.1A apply.

#### W.2.2.1B Re-establishment of the IP-CAN used for SIP signalling

The procedures specified in Annex U.2.2.1B apply.

#### W.2.2.1C P-CSCF restoration procedure

The procedures specified in Annex U.2.2.1C apply.

## W.2.2.2 Session management procedures

The procedures specified in Annex U.2.2.2 apply.

## W.2.2.3 Mobility management procedures

The procedures specified in Annex U.2.2.3 apply.

## W.2.2.4 Cell selection and lack of coverage

Not applicable.

## W.2.2.5 5GS QoS flow for media

### W.2.2.5.1 General requirements

NOTE 1: During establishment of a session, the UE establishes data streams(s) for media related to the session. Either the UE or the network can request for resource allocations for media, but the establishment and modification of the 5GS QoS flow is controlled by the network as described in 3GPP TS 24.501 [258].

If the resource allocation is initiated by the UE, the UE starts reserving resources whenever it has sufficient information about the media streams, and used codecs available as specified in 3GPP TS 24.501 [258] and 3GPP TS 24.502 [263].

NOTE 2: If the resource reservation requests are initiated by the network, then the establishment of 5GS QoS flow for media is initiated by the network after the P-CSCF has authorised the respective 5GS QoS flows and provided the QoS requirements to the PCF.

### W.2.2.5.1A Activation or modification of QoS flows for media by the UE

If the UE is configured not to initiate resource allocation for media according to 3GPP TS 24.167 [8G], then the UE shall refrain from requesting additional 5GS QoS flow(s) for media until the UE considers that the network did not initiate resource allocation for the media.

### W.2.2.5.1B Activation or modification of QoS flows for media by the network

If the UE receives an activation request from the network for a 5GS QoS flow for media which is associated with the 5GS QoS flow used for signalling, the UE shall correlate the media 5GS QoS flow with a currently ongoing SIP session establishment or SIP session modification.

If the UE receives a modification request from the network for a 5GS QoS flow that is used for one or more media streams in an ongoing SIP session, the UE shall:

- 1) modify the related PDU session context in accordance with the request received from the network.

### W.2.2.5.1C Deactivation of a QoS flow for media

When a data stream for media related to a session is released, if the 5GS QoS flow transporting the data stream is no longer needed and allocation of the 5GS QoS flow was requested by the UE, then the UE releases the 5GS QoS flow.

NOTE: The 5GS QoS flow can be needed e.g. for other data streams of a session or for other applications in the UE.

### W.2.2.5.2 Special requirements applying to forked responses

The procedures specified in Annex U.2.2.5.2 apply.

### W.2.2.5.3 Unsuccessful situations

Not applicable.

## W.2.2.6 Emergency service

### W.2.2.6.1 General

Emergency session is supported over the WLAN access if the UE has failed or has not been able to use 3GPP access to set up an emergency session as described in 3GPP TS 23.167 [4B] annex L. IMS emergency session is also supported for UEs with unavailable IMSI (i.e. a UE without USIM) or unauthenticated IMSI.

Some jurisdictions allow emergency calls to be made when the UE does not contain an ISIM or USIM, or where the credentials are not accepted.

The UE determines that the 5GCN supports emergency services via WLAN when the Emergency service support for non-3GPP (EMCN3) access indicator in the REGISTRATION ACCEPT message indicates emergency services are supported over non-3GPP access as defined in subclause 9.11.3.5 of 3GPP TS 24.501 [258].

When the UE is registered over a WLAN access and detects an emergency call attempt, if the UE supports the emerg-non3gpp timer defined in table 7.8.1 and has determined that 5GCN supports emergency services via WLAN the UE shall start the emerg-non3gpp timer when starting a domain selection searching for a 3GPP access usable to establish an emergency call. The UE shall stop the timer when a 3GPP access supporting emergency call is found. When the emerg-non3gpp timer expires the UE shall consider that it has failed to use 3GPP access to setup the emergency call and shall attempt to setup the emergency call over the available WLAN access.

The UE may support being configured for the emerg-non3gpp timer using one or more of the following methods:

- a) the Timer\_Emerg\_non3gpp leaf of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the Timer\_Emerg\_non3gpp leaf of the EF<sub>IMSConfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the Timer\_Emerg\_non3gpp leaf of 3GPP TS 24.167 [8G].

When the IM CN subsystem is selected as the domain for the emergency call attempt, the UE determines whether it is currently attached to its home operator's network (e.g. HPLMN) or not (e.g. VPLMN) after it has determined that the 5GCN supports emergency services via WLAN.

To perform emergency registration, the UE shall request to establish an emergency PDU session as described in 3GPP TS 24.501 [258]. The procedures for PDU session establishment and P-CSCF discovery, as described in subclause W.2.2.1 of this specification apply accordingly.

If the ME is equipped with a UICC, in order to find out whether the UE is attached to the home PLMN or to the visited PLMN, the UE shall compare the MCC and MNC values derived from its IMSI with the MCC and MNC of the PLMN the UE is attached to. If the MCC and MNC of the PLMN the UE is attached to do not match with the MCC and MNC derived from the IMSI, then for the purposes of emergency calls in the IM CN subsystem the UE shall consider to be attached to a VPLMN. If the ME is not equipped with a UICC, the procedure to find out whether the UE is attached to the home PLMN or to the visited PLMN for the purpose of emergency calls in the IM CN subsystem, is implementation specific.

NOTE: The UE verifies if a detected emergency number is still present in the Extended Local Emergency Number List applicable to the PLMN it is currently using. It is possible for the number to no longer be present in the Extended Local Emergency Number List if:

- the PLMN attached to relies on the Local Emergency Number List for deriving a URN; or
- the previously received Extended Emergency Number List Validity field indicated "Extended Local Emergency Numbers List is valid only in the PLMN from which this IE is received".

If the UE detected an emergency number, the UE subsequently uses a different PLMN than the PLMN from which the UE received the last Extended Local Emergency Number List, the dialled number is not stored in the ME, in the USIM and in the Local Emergency Number List, and:

- the REGISTRATION ACCEPT message received from the different PLMN contains the Extended Local Emergency Number List and the emergency number is present in the updated Extended Local Emergency Number List then the UE uses the updated Extended Local Emergency Number List when it performs the procedures in subclause W.2.2.6.1B; and

- the REGISTRATION ACCEPT message received from the different PLMN contains no Extended Local Emergency Number List or the emergency number is no longer present in the updated Extended Local Emergency Number List then the UE shall attempt UE procedures for SIP that relate to emergency using emergency service URN "urn:service:sos".

If the dialled number is equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]), then the UE shall recognize such a number as for an emergency call and:

- if the dialled number is equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform either procedures in the subclause W.2.2.6.1B or the procedures in subclause W.2.2.6.1A; and
- if the dialled number is not equal to an emergency number stored in the ME, or in the USIM, then the UE shall perform procedures in the subclause W.2.2.6.1B.

If the dialled number is not equal to a local emergency number stored in the Extended Local Emergency Number List (as defined in 3GPP TS 24.301 [8J]) and:

- if the dialled number is equal to an emergency number stored in the ME, in the USIM or in the Local Emergency Number List (as defined in 3GPP TS 24.008 [8]), then the UE shall recognize such a number as for an emergency call and performs the procedures in subclause W.2.2.6.1A.

Once IPsec tunnel setup is completed, the UE shall follow the procedures described in subclause W.2.2.1 of this specification for establishment of IP-CAN bearer and P-CSCF discovery accordingly.

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, if:

- the 380 (Alternate Service) response contains a Contact header field;
- the value of the Contact header field is a service URN; and
- the service URN has a top-level service type of "sos";

then the UE determines that "emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.3.1, if the 380 (Alternate Service) response does not contain a Contact header field with service URN that has a top-level service type of "sos", then the UE determines that "no emergency service information is included" as described 3GPP TS 23.167 [4B].

Upon reception of a 380 (Alternative Service) response to an INVITE request as defined in subclause 5.1.2A.1.1 and subclause 5.1.3.1, the UE shall proceed as follows:

- 1) if a 3GPP access network is available and the UE has not already attempted to use a 3GPP access network to set up an emergency session as described in 3GPP TS 23.167 [4B] annex L, when the UE selects a domain in accordance with the conventions and rules specified in 3GPP TS 22.101 [1A] and 3GPP TS 23.167 [4B], the UE shall attempt to select a domain of the 3GPP access network, and:
  - if the CS domain is selected, the UE behaviour is defined in subclause 7.1.2 of 3GPP TS 23.167 [4B] and in annex B; and
  - if the IM CN subsystem is selected, the UE shall apply the procedures in subclause 5.1.6 with the exception of selecting a domain for the emergency call attempt;

In addition, when the UE determines that "it has not been able to use 3GPP access to set up an emergency session" in accordance with subclause L.1 of 3GPP TS 23.167 [4B], the UE shall apply the procedures in subclause 5.1.6 using WLAN, with the exception of selecting a domain for the emergency call attempt; and

- 2) if a 3GPP access network is not available, then the UE shall apply the procedures in subclause 5.1.6 using WLAN, with the exception of selecting a domain for the emergency call attempt.

When the emergency registration expires, the UE should disconnect the emergency PDU session.

#### W.2.2.6.1A Type of emergency service derived from emergency service category value

Annex U.2.2.6.1A applies.

#### W.2.2.6.1B Type of emergency service derived from extended local emergency number list

Annex U.2.2.6.1B applies.

#### W.2.2.6.2 eCall type of emergency service

The UE shall not send an INVITE request with Request-URI set to "urn:service:sos.ecall.manual" or "urn:service:sos.ecall.automatic".

#### W.2.2.6.3 Current location discovery during an emergency call

The UE may support the current location discovery during an emergency call specified in subclause 5.1.6.8.2, subclause 5.1.6.8.3, subclause 5.1.6.8.4, and subclause 5.1.6.12.

---

## W.2A Usage of SDP

### W.2A.0 General

Not applicable.

### W.2A.1 Impact on SDP offer / answer of activation or modification of IP-CAN for media by the network

The procedures specified in Annex U.2A.1 apply.

### W.2A.2 Handling of SDP at the terminating UE when originating UE has resources available and IP-CAN performs network-initiated resource reservation for terminating UE

Not applicable.

### W.2A.3 Emergency service

No additional procedures defined.

---

## W.3 Application usage of SIP

### W.3.1 Procedures at the UE

#### W.3.1.0 Registration and authentication

The procedures specified in Annex U.3.1.0 apply with the following clarification:

- the UE shall perform reregistration of a previously registered public user identity bound to any one of its contact addresses when changing to an IP-CAN for which usage is specified in annex U or annex L.

### W.3.1.0aIMS\_Registration\_handling policy

The IMS\_Registration\_handling policy indicates whether the UE deregisters from IMS after a configured amount of time after receiving an indication that the IMS Voice over PS Session is not supported.

The UE may support the IMS\_Registration\_handling policy.

If the UE supports the IMS\_Registration\_handling policy, the UE may support being configured with the IMS\_Registration\_handling policy using one or more of the following methods:

- a) the IMS\_Registration\_Policy node of the EF<sub>IMSCconfigData</sub> file described in 3GPP TS 31.102 [15C];
- b) the IMS\_Registration\_Policy node of the EF<sub>IMSCconfigData</sub> file described in 3GPP TS 31.103 [15B]; and
- c) the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G].

If the UE is configured with both the IMS\_Registration\_Policy node of 3GPP TS 24.167 [8G] and the IMS\_Registration\_Policy node of the EF<sub>IMSCconfigData</sub> file described in 3GPP TS 31.102 [15C] or 3GPP TS 31.103 [15B], then the IMS\_Registration\_Policy node of the EF<sub>IMSCconfigData</sub> file shall take precedence.

NOTE 1: Precedence for files configured on both the USIM and ISIM is defined in 3GPP TS 31.103 [15B].

If the UE is registered with IMS and the IMSVoPS indicator, provided by the lower layers (see 3GPP TS 24.501 [258]), indicates voice is not supported, the UE shall:

- A) if the Stay\_Registered\_When\_VoPS\_Not\_Supported leaf indicates requirement to stay registered, the UE needs not to deregister and maintains the registration as required for IMS services; or

NOTE 2: The UE will periodically refresh the registration when needed.

- B) if the Stay\_Registered\_When\_VoPS\_Not\_Supported leaf indicates requirement to deregister and the Deregistration\_Timer leaf used to configure the NoVoPS-dereg timer defined in table 7.8.1 contains a timer value for the time to wait before deregistering from IMS, start a timer with the value indicated in the policy and:

- a) if the timer expires before the UE receives an indication from the lower layers that IMS voice is supported:
  - 1) if there is no ongoing IMS session, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6; or
  - 2) if there is ongoing IMS session, and
    - i) if the UE does not receive indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, the UE either performs reregistration as specified in subclause 5.1.1.4 and shall only include feature tags associated with services that are independent of IMSVoPS indicator or deregister from the IMS following the procedures specified in subclause 5.1.1.6 as soon as the ongoing IMS based service is terminated; or
    - ii) if the UE receives indication from the lower layer that the IMS voice is supported before the ongoing IMS session is terminated, cancel the timer; or

NOTE 3: How the UE selects reregistration or deregistration is implementation dependent (e.g., SMS service)

- b) if the UE receives an indication from the lower layers that IMS voice is supported before the timer expires, cancel the timer.

If the IMS\_Registration\_handling policy is not configured, the UE behaviour is implementation specific.

#### W.3.1.1 P-Access-Network-Info header field

The UE shall always include the P-Access-Network-Info header field where indicated in subclause 5.1.

### W.3.1.1A Cellular-Network-Info header field

The UE:

- 1) using the 5GCN via Wireless Local Access Network (WLAN) as IP-CAN to access the IM CN subsystem; and
- 2) supporting one or more cellular radio access technology (e.g. NR);

shall always include the Cellular-Network-Info header field specified in subclause 7.2.15, if the information is available, in every request or response in which the P-Access-Network-Info header field is present.

### W.3.1.2 Availability for calls

Not applicable.

### W.3.1.2A Availability for SMS

Void.

### W.3.1.3 Authorization header field

Void.

### W.3.1.4 SIP handling at the terminating UE when precondition is not supported in the received INVITE request, the terminating UE does not have resources available and IP-CAN performs network-initiated resource reservation for the terminating UE

Not applicable.

### W.3.1.5 3GPP PS data off

Not applicable.

### W.3.1.6 Transport mechanisms

Void.

### W.3.1.7 RLOS

Not applicable.

## W.3.2 Procedures at the P-CSCF

### W.3.2.0 Registration and authentication

Void.

### W.3.2.1 Determining network to which the originating user is attached

The procedures specified in Annex U.3.2.1 apply.

### W.3.2.2 Location information handling

Void.

### W.3.2.3 Prohibited usage of PDN connection for emergency bearer services

The procedures specified in Annex U.3.2.3 apply.

### W.3.2.4 Support for paging policy differentiation

Void.

### W.3.2.5 Void

### W.3.2.6 Resource sharing

The feature is not supported in this release of the specification.

### W.3.2.7 Priority sharing

The feature is not supported in this release of the specification

### W.3.2.8 RLOS

Not applicable.

## W.3.3 Procedures at the S-CSCF

### W.3.3.1 Notification of AS about registration status

Not applicable.

### W.3.3.2 RLOS

Not applicable.

---

## W.4 3GPP specific encoding for SIP header field extensions

### W.4.1 Void

---

## W.5 Use of circuit-switched domain

Void.

---

# Annex X (informative): Support of SBA in IMS

## X.1 Scope

This annex describes support for SBA for IMS nodes.

IMS nodes can use the SBA interfaces described in the present Annex as an alternative to the Diameter Rx and Cx and Sh reference points based on configuration. To support co-existence of IMS nodes supporting SBA services and IMS nodes not supporting SBA services SBI, enabled IMS nodes can support both SBI and non-SBI interfaces.

While the main body of the present document only describes usage of Diameter Rx and Cx and Sh reference points, the usage of the equivalent SBA services is a valid option.

NOTE 1: This version of the specification does not specify the details for usage of SBIs by P-CSCF, S-CSCF, I-CSCF and AS in the main body of the specification.

NOTE 2: This annex is intended to be used in conjunction with 5GC, see Annex U and Annex W.

---

## X.2 Reference points to support SBA in IMS

The following IMS related reference points are realized by service-based interfaces:

- **N5**: Reference point between the PCF and an AF.

NOTE 1: The P-CSCF acts as an AF from the PCF point of view. The N5 Reference point is defined in 3GPP TS 23.501 [257] and the related protocol specification is in 3GPP TS 29.514 [273]. It provides equivalent functionality to the Diameter-based Rx reference point.

- **N70**: Reference point between an SBI capable I/S-CSCF and an SBI capable HSS.

NOTE 2: The N70 Reference point is defined in 3GPP TS 23.501 [257] and the related protocol specification is in 3GPP TS 29.562 [274]. It provides equivalent functionality to the Diameter-based Cx reference point.

- **N71**: Reference point between an SBI capable IMS AS and an SBI capable HSS.

NOTE 3: The N71 Reference point is defined in 3GPP TS 23.501 [257] and the related protocol specification is in 3GPP TS 29.562 [274]. It provides equivalent functionality to the Diameter-based Sh reference point.

---

## X.3 Services to support SBA in IMS

If a P-CSCF uses the Npcf\_PolicyAuthorization service, it will apply Npcf\_PolicyAuthorization service operations (defined in 3GPP TS 29.514[273]) instead of Rx procedures (defined in 3GPP TS 29.214[13D]) and will interact with the PCF instead of the PCRF.

- **Npcf\_PolicyAuthorization**: This service is provided by the PCF. This service is to authorise an AF request and to create policies as requested by the authorized AF for the PDU Session to which the AF session is bound. This service also allows the NF service consumer to subscribe/unsubscribe the notification of events.

NOTE 1: The P-CSCF acts as an AF from the PCF point of view. The Npcf\_PolicyAuthorization service is defined in 3GPP TS 23.502 [275] and the related protocol specification is in 3GPP TS 29.514 [273]. It provides equivalent functionality to the Diameter-based Rx reference point.

If an I-CSCF or an S-CSCF uses the Nhss\_ims services, it will apply Nhss\_ims service operations instead of Cx procedures mentioned throughout the present specification and will interact with an SBI capable HSS.

- **Nhss\_imsUEContextManagement**: This service is provided by an SBI capable HSS. It enables service operations related to the management of a UE context.

- **Nhss\_imsSubscriberDataManagement:** This service is provided by an SBI capable HSS. It enables service operations related to subscriber data management.
- **Nhss\_imsUEAuthentication:** This service is provided by an SBI capable HSS. It enables a service operation related to the authentication between the end user and the home IMS network.

NOTE 2: The Nhss\_imsUEContextManagement, Nhss\_imsSubscriberDataManagement, and Nhss\_imsUEAuthentication services are defined in annex AA of 3GPP TS 23.228 [7] and the related protocol specification is in 3GPP TS 29.562 [274]. They provide equivalent functionality to the Diameter-based Cx and Sh reference point.

NOTE 3: The Nhss\_imsUEAuthentication service is not consumed by I-CSCF.

NOTE 4: The Nhss\_imsUEAuthentication and Nhss\_imsUEContextManagement services are not consumed by AS.

## Annex Y (informative): Change history
