## Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (http://webapp.etsi.org/IPR/home.asp).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

#### **Foreword**

This Technical Specification (TS) has been produced by ETSI 3rd Generation Partnership Project (3GPP).

The present document may refer to technical specifications or reports using their 3GPP identities, UMTS identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables.

The cross reference between GSM, UMTS, 3GPP and ETSI identities can be found under <a href="http://webapp.etsi.org/key/queryform.asp">http://webapp.etsi.org/key/queryform.asp</a>.

## **Foreword**

This Technical Specification (TS) has been produced by the 3<sup>rd</sup> Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

#### where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 or greater indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the document.

## 1 Scope

The present document describes spreading and modulation for UTRA Physical Layer FDD mode.

## 2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document *in the same Release as the present document*.

## 3 Symbols and abbreviations

## 3.1 Symbols

For the purposes of the present document, the following symbols apply:

C<sub>ch,SF,n</sub>: n:th channelisation code with spreading factor SF

 $C_{pre,n,s}$ : PRACH preamble code for n:th preamble scrambling code and signature s

 $C_{sig,s}$ : PRACH signature code for signature s

 $S_{dpch,n}$ : n:th DPCCH/DPDCH uplink scrambling code  $S_{r-pre,n}$ : n:th PRACH preamble scrambling code  $S_{r-msg,n}$ : n:th PRACH message scrambling code

 $S_{dl,n}$ : DL scrambling code

 $C_{psc}$ : PSC code  $C_{ssc,n}$ : n:th SSC code

#### 3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

16QAM 16 Quadrature Amplitude Modulation AICH Acquisition Indicator Channel

BCH Broadcast Control Channel

CCPCH Common Control Physical Channel

CPICH Common Pilot Channel DCH Dedicated Channel

DPCH Dedicated Physical Channel

## 4 Uplink spreading and modulation

#### 4.1 Overview

Spreading is applied to the physical channels. It consists of two operations. The first is the channelisation operation, which transforms every data symbol into a number of chips, thus increasing the bandwidth of the signal. The number of chips per data symbol is called the Spreading Factor (SF). The second operation is the scrambling operation, where a scrambling code is applied to the spread signal.

With the channelisation, data symbols on so-called I- and Q-branches are independently multiplied with an OVSF code. With the scrambling operation, the resultant signals on the I- and Q-branches are further multiplied by complex-valued scrambling code, where I and Q denote real and imaginary parts, respectively.

## 4.2 Spreading

## 4.2.1 Dedicated physical channels

The possible combinations of the maximum number of respective dedicated physical channels which may be configured simultaneously for a UE in addition to the DPCCH are specified in table 0. The actual UE capability may be lower than the values specified in table 0; the actual dedicated physical channel configuration is indicated by higher layer signalling. The actual number of configured DPDCHs, denoted  $N_{max-dpdch}$ , is equal to the largest number of DPDCHs from all the TFCs in the TFCS.  $N_{max-dpdch}$  is not changed by frame-by-frame TFCI change or temporary TFC restrictions.

Table 0: Maximum number of simultaneously-configured uplink dedicated channels

	DPDCH	HS-DPCCH	E-DPDCH	E-DPCCH
Case 1	6	1	-	-
Case 2	1	1	2	1
Case 3	-	1	4	1

Figure 1 illustrates the principle of the spreading of uplink dedicated physical channels (DPCCH, DPDCHs, HSDPCCH, E-DPDCHs).

The binary input sequences of all physical channels are converted to real valued sequences, i.e. the binary value "0" is mapped to the real value +1, the binary value "1" is mapped to the real value -1, and the value "DTX" (HS-DPCCH only) is mapped to the real value 0.

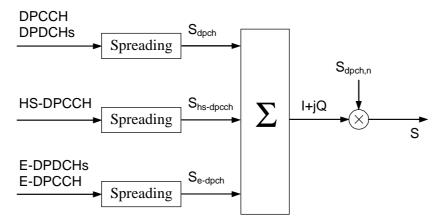

Figure 1: Spreading for uplink dedicated channels

The spreading operation is specified in subclauses 4.2.1.1 to 4.2.1.3 for each of the dedicated physical channels; it includes a spreading stage, a weighting stage, and an IQ mapping stage. In the process, the streams of real-valued chips on the I and Q branches are summed; this results in a complex-valued stream of chips for each set of channels.

As described in figure 1, the resulting complex-valued streams  $S_{dpch}$ ,  $S_{hs\text{-dpcch}}$  and  $S_{e\text{-dpch}}$  are summed into a single complex-valued stream which is then scrambled by the complex-valued scrambling code  $S_{dpch,n}$ . The scrambling code shall be applied aligned with the radio frames, i.e. the first scrambling chip corresponds to the beginning of a radio frame.

NOTE: Although subclause 4.2.1 has been reorganized in this release, the spreading operation for the DPCCH, DPDCH remains unchanged as compared to the previous release.

#### 4.2.1.1 DPCCH/DPDCH

Figure 1a illustrates the spreading operation for the uplink DPCCH and DPDCHs.

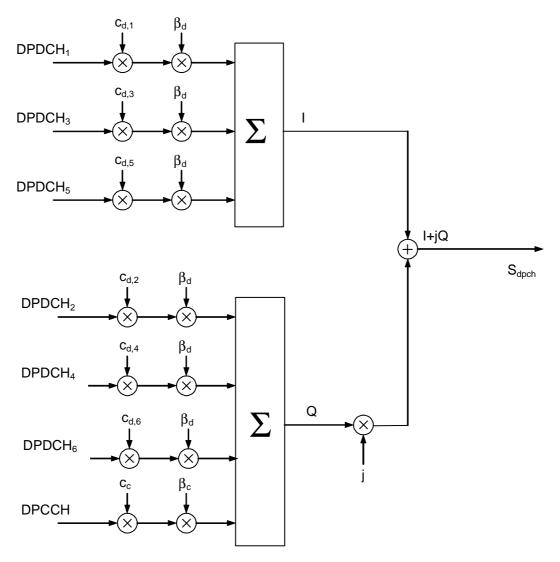

Figure 1A: Spreading for uplink DPCCH/DPDCHs

The DPCCH is spread to the chip rate by the channelisation code  $c_c$ . The n:th DPDCH called DPDCH<sub>n</sub> is spread to the chip rate by the channelisation code  $c_{d,n}$ .

After channelisation, the real-valued spread signals are weighted by gain factors,  $\beta_c$  for DPCCH,  $\beta_d$  for all DPDCHs.

The  $\beta_c$  and  $\beta_d$  values are signalled by higher layers or derived as described in [6] 5.1.2.5 and 5.1.2.5C. At every instant in time, at least one of the values  $\beta_c$  and  $\beta_d$  has the amplitude 1.0. The  $\beta_c$  and  $\beta_d$  values are quantized into 4 bit words. The quantization steps are given in table 1.

Signalled values for $\beta_c$ and $\beta_d$	Quantized amplitude ratios $\beta_c$ and $\beta_d$

Table 1: The quantization of the gain parameters

#### 4.2.1.2 HS-DPCCH

Figure 1b illustrates the spreading operation for the HS-DPCCH.

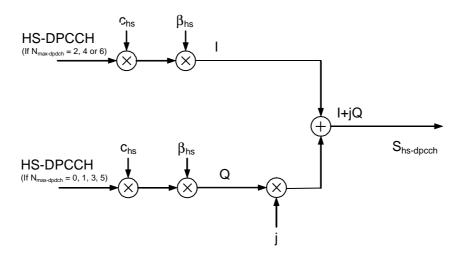

Figure 1B: Spreading for uplink HS-DPCCH

The HS-DPCCH shall be spread to the chip rate by the channelisation code chs.

After channelisation, the real-valued spread signals are weighted by gain factor  $\beta_{\text{hs}}$ 

The  $\beta_{hs}$  values are derived from the quantized amplitude ratios  $A_{hs}$  which are translated from  $\Delta_{ACK}$ ,  $\Delta_{NACK}$  and  $\Delta_{CQI}$  signalled by higher layers as described in [6] 5.1.2.5A.

The translation of  $\Delta_{ACK}$ ,  $\Delta_{NACK}$  and  $\Delta_{CQI}$  into quantized amplitude ratios  $A_{hs} = \beta_{hs}/\beta_c$  is shown in Table 1A.

Signalled values for $\Delta$ ACK, $\Delta_{NACK}$ and $\Delta_{CQI}$	Quantized amplitude ratios $A_{hs} = \beta_{hs}/\beta_c$

Table 1A: The quantization of the power offset

HS-DPCCH shall be mapped to the I branch in case  $N_{max-dpdch}$  is 2, 4 or 6, and to the Q branch otherwise ( $N_{max-dpdch} = 0, 1, 3 \text{ or } 5$ ).

#### 4.2.1.3 E-DPDCH/E-DPCCH

Figure 1c illustrates the spreading operation for the E-DPDCHs and the E-DPCCH.

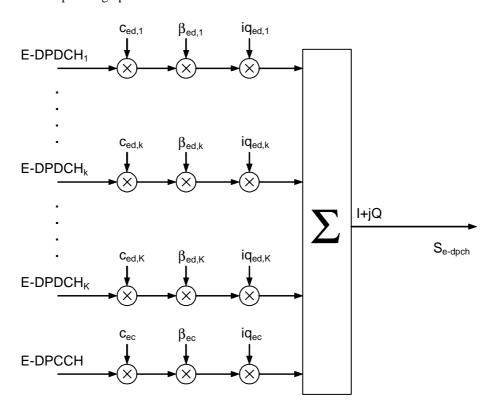

Figure 1c: Spreading for E-DPDCH/E-DPCCH

The E-DPCCH shall be spread to the chip rate by the channelisation code  $c_{ec}$ . The k:th E-DPDCH, denominated E-DPDCH<sub>k</sub>, shall be spread to the chip rate using channelisation code  $c_{ed,k}$ .

After channelisation, the real-valued spread E-DPCCH and E-DPDCH<sub>k</sub> signals shall respectively be weighted by gain factor  $\beta_{ec}$  and  $\beta_{ed,k}$ .

The value of  $\beta_{ec}$  shall be derived as specified in [6] based on the quantized amplitude ratio  $A_{ec}$  which is translated from  $\Delta_{E\text{-DPCCH}}$  signalled by higher layers. The translation of  $\Delta_{E\text{-DPCCH}}$  into quantized amplitude ratios  $A_{ec} = \beta_{ec}/\beta_c$  is specified in Table 1B.

Table 1B: Quantization for  $\Delta_{\text{E-DPCCH}}$ 

Signalled values for $\Delta$	Quantized amplitude ratios
E-DPCCH	$A_{ec} = \beta_{ec}/\beta_{c}$

5	15/15
4	12/15
3	9/15
2	8/15
1	6/15
0	5/15

The value of  $\beta_{ed,k}$  shall be computed as specified in [6] subclause 5.1.2.5B.2, based on the reference gain factors, the spreading factor for E-DPDCH<sub>k</sub>, the HARQ offsets, and the quantization of the ratio  $\beta_{ed,k}/\beta_c$  into amplitude ratios specified in Table 1B.2.

The reference gain factors are derived from the quantised amplitude ratios  $A_{ed}$  which is translated from  $\Delta_{E\text{-DPDCH}}$  signalled by higher layers. The translation of  $\Delta_{E\text{-DPDCH}}$  into quantized amplitude ratios  $A_{ed} = \beta_{ed}/\beta_c$  is specified in Table 1B.1.

After weighting, the real-valued spread signals shall be mapped to the I branch or the Q branch according to the  $iq_{ec}$  value for the E-DPCCH and to  $iq_{ed,k}$  for E-DPDCH<sub>k</sub> and summed together.

The E-DPCCH shall always be mapped to the I branch, i.e.  $iq_{ec} = 1$ .

The IQ branch mapping for the E-DPDCHs depends on  $N_{\text{max-dpdch}}$  and on whether an HS-DSCH is configured for the UE; the IQ branch mapping shall be as specified in table 1C.

**HS-DSCH** E-DPDCH<sub>k</sub> N<sub>max-dpdch</sub> iq<sub>ed,k</sub> configured E-DPDCH<sub>1</sub> 1 0 No/Yes E-DPDCH<sub>2</sub> E-DPDCH<sub>3</sub> 1 E-DPDCH<sub>4</sub> E-DPDCH<sub>1</sub> 1 No E-DPDCH<sub>2</sub> 1 E-DPDCH<sub>1</sub> 1 Yes 1 E-DPDCH<sub>2</sub>

Table 1C: IQ branch mapping for E-DPDCH

NOTE: In case the UE transmits more than 2 E-DPDCHs, the UE then always transmits E-DPDCH<sub>3</sub> and E-DPDCH<sub>4</sub> simultaneously

#### 4.2.2 PRACH

#### 4.2.2.1 PRACH preamble part

The PRACH preamble part consists of a complex-valued code, described in subclause 4.3.3.

#### 4.2.2.2 PRACH message part

Figure 2 illustrates the principle of the spreading and scrambling of the PRACH message part, consisting of data and control parts. The binary control and data parts to be spread are represented by real-valued sequences, i.e. the binary value "0" is mapped to the real value +1, while the binary value "1" is mapped to the real value -1. The control part is spread to the chip rate by the channelisation code  $c_c$ , while the data part is spread to the chip rate by the channelisation code  $c_d$ .

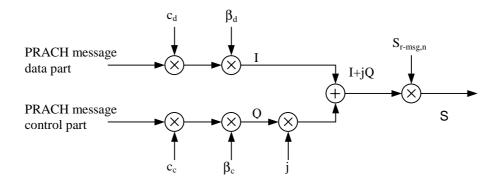

Figure 2: Spreading of PRACH message part

After channelisation, the real-valued spread signals are weighted by gain factors,  $\beta_c$  for the control part and  $\beta_d$  for the data part. At every instant in time, at least one of the values  $\beta_c$  and  $\beta_d$  has the amplitude 1.0. The  $\beta$ -values are quantized into 4 bit words. The quantization steps are given in subclause 4.2.1.

After the weighting, the stream of real-valued chips on the I- and Q-branches are treated as a complex-valued stream of chips. This complex-valued signal is then scrambled by the complex-valued scrambling code  $S_{r-msg,n}$ . The 10 ms scrambling code is applied aligned with the 10 ms message part radio frames, i.e. the first scrambling chip corresponds to the beginning of a message part radio frame.

#### 4.2.3 Void

## 4.3 Code generation and allocation

#### 4.3.1 Channelisation codes

#### 4.3.1.1 Code definition

The channelisation codes of figure 1 are Orthogonal Variable Spreading Factor (OVSF) codes that preserve the orthogonality between a user"s different physical channels. The OVSF codes can be defined using the code tree of figure 4.

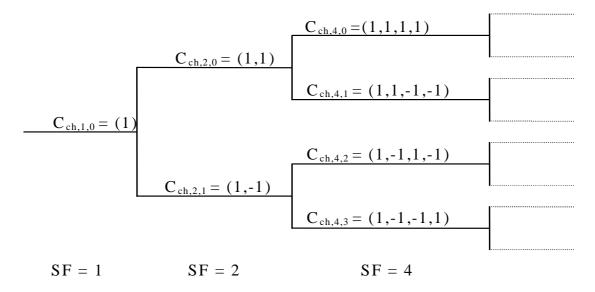

Figure 4: Code-tree for generation of Orthogonal Variable Spreading Factor (OVSF) codes

In figure 4, the channelisation codes are uniquely described as  $C_{ch,SF,k}$ , where SF is the spreading factor of the code and k is the code number,  $0 \le k \le SF-1$ .

Each level in the code tree defines channelisation codes of length SF, corresponding to a spreading factor of SF in figure 4.

The generation method for the channelisation code is defined as:

$$\begin{aligned} & C_{\mathrm{ch},1,0} = 1\,, \\ & \begin{bmatrix} C_{ch,2,0} \\ C_{ch,2,1} \end{bmatrix} = \begin{bmatrix} C_{ch,1,0} & C_{ch,1,0} \\ C_{ch,1,0} & -C_{ch,1,0} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \\ & \begin{bmatrix} C_{ch,2}(n+1)_{,0} \\ C_{ch,2}(n+1)_{,1} \\ C_{ch,2}(n+1)_{,2} \\ C_{ch,2}(n+1)_{,3} \\ \vdots \\ C_{ch,2}(n+1)_{,2}(n+1)_{-2} \\ C_{ch,2}(n+1)_{,2}(n+1)_{-1} \end{bmatrix} = \begin{bmatrix} C_{ch,2^n,0} & C_{ch,2^n,0} \\ C_{ch,2^n,0} & -C_{ch,2^n,0} \\ C_{ch,2^n,1} & C_{ch,2^n,1} \\ \vdots & \vdots \\ C_{ch,2^n,1} & -C_{ch,2^n,1} \\ \vdots & \vdots \\ C_{ch,2^n,2^n-1} & C_{ch,2^n,2^n-1} \\ C_{ch,2^n,2^n-1} & -C_{ch,2^n,2^n-1} \end{bmatrix}$$

The leftmost value in each channelisation code word corresponds to the chip transmitted first in time.

#### 4.3.1.2 Code allocation for dedicated physical channels

NOTE: Although subclause 4.3.1.2 has been reorganized in this release, the spreading operation for DPCCH and DPDCH remains unchanged as compared to the previous release.

#### 4.3.1.2.1 Code allocation for DPCCH/DPDCH

For the DPCCH and DPDCHs the following applies:

- The DPCCH shall always be spread by code  $c_c = C_{ch,256,0}$
- When only one DPDCH is to be transmitted, DPDCH<sub>1</sub> shall be spread by code  $c_{d,1} = C_{ch,SF,k}$  where SF is the spreading factor of DPDCH<sub>1</sub> and k = SF / 4.
- When more than one DPDCH is to be transmitted, all DPDCHs have spreading factors equal to 4. DPDCH<sub>n</sub> shall be spread by the the code  $c_{d,n} = C_{ch,4,k}$ , where k = 1 if  $n \in \{1, 2\}$ , k = 3 if  $n \in \{3, 4\}$ , and k = 2 if  $n \in \{5, 6\}$ .

If a power control preamble is used to initialise a DCH, the channelisation code for the DPCCH during the power control preamble shall be the same as that to be used afterwards.

#### 4.3.1.2.2 Code allocation for HS-DPCCH

The HS-DPCCH shall be spread with code  $c_{hs}$  as specified in table 1D.

Table 1D: channelisation code of HS-DPCCH

N <sub>max-dpdch</sub> (as defined in subclause 4.2.1)	Channelisation code c <sub>hs</sub>
0	C ch,256,33
1	C <sub>ch,256,64</sub>
2,4,6	C <sub>ch,256,1</sub>
3,5	C <sub>ch,256,32</sub>

#### 4.3.1.2.3 Code allocation for E-DPCCH/E-DPDCH

The E-DPCCH shall be spread with channelisation code  $c_{ec} = C_{ch,256,1}$ .

 $E ext{-DPDCH}_k$  shall be spread with channelisation code  $c_{ed,k}$ . The sequence  $c_{ed,k}$  depends on  $N_{max ext{-dpdch}}$  and the spreading factor selected for the corresponding frame or sub-frame as specified in [7]; it shall be selected according to table 1E.

Table 1E: Channelisation code for E-DPDCH

N <sub>max-dpdch</sub>	E-DPDCH <sub>k</sub>	Channelisation code C <sub>ed,k</sub>
0	E-DPDCH <sub>1</sub>	$\begin{array}{c} C_{\text{ch,SF,SF/4}} \text{ if SF} \geq 4 \\ C_{\text{ch,2,1}} \text{ if SF} = 2 \end{array}$
	E-DPDCH <sub>2</sub>	$C_{ch,4,1}$ if SF = 4 $C_{ch,2,1}$ if SF = 2
	E-DPDCH <sub>3</sub> E-DPDCH <sub>4</sub>	C <sub>ch,4,1</sub>
1	E-DPDCH₁	C <sub>ch,SF,SF/2</sub>
	E-DPDCH <sub>2</sub>	$C_{ch,4,2}$ if SF = 4 $C_{ch,2,1}$ if SF = 2

NOTE: When more than one E-DPDCH is transmitted, the respective channelisation codes used for E-DPDCH<sub>1</sub> and E-DPDCH<sub>2</sub> are always the same.

#### 4.3.1.3 Code allocation for PRACH message part

The preamble signature s,  $0 \le s \le 15$ , points to one of the 16 nodes in the code-tree that corresponds to channelisation codes of length 16. The sub-tree below the specified node is used for spreading of the message part. The control part is spread with the channelisation code  $c_c$  (as shown in subclause 4.2.2.2) of spreading factor 256 in the lowest branch of the sub-tree, i.e.  $c_c = C_{ch,256,m}$  where  $m = 16 \times s + 15$ . The data part uses any of the channelisation codes from spreading factor 32 to 256 in the upper-most branch of the sub-tree. To be exact, the data part is spread by channelisation code  $c_d = C_{ch,SF,m}$  and SF is the spreading factor used for the data part and  $m = SF \times s/16$ .

- 4.3.1.4 Void
- 4.3.1.5 Void

#### 4.3.2 Scrambling codes

#### 4.3.2.1 General

All uplink physical channels shall be scrambled with a complex-valued scrambling code. The dedicated physical channels may be scrambled by either a long or a short scrambling code, defined in subclause 4.3.2.4. The PRACH message part shall be scrambled with a long scrambling code, defined in subclause 4.3.2.5. There are 2<sup>24</sup> long and 2<sup>24</sup> short uplink scrambling codes. Uplink scrambling codes are assigned by higher layers.

The long scrambling code is built from constituent long sequences defined in subclause 4.3.2.2, while the constituent short sequences used to build the short scrambling code are defined in subclause 4.3.2.3.

#### 4.3.2.2 Long scrambling sequence

The long scrambling sequences  $c_{long,1,n}$  and  $c_{long,2,n}$  are constructed from position wise modulo 2 sum of 38400 chip segments of two binary m-sequences generated by means of two generator polynomials of degree 25. Let x, and y be the two m-sequences respectively. The x sequence is constructed using the primitive (over GF(2)) polynomial  $X^{25} + X^3 + I$ . The y sequence is constructed using the polynomial  $X^{25} + X^3 + X^2 + X + I$ . The resulting sequences thus constitute segments of a set of Gold sequences.

The sequence  $c_{long,2,n}$  is a 16777232 chip shifted version of the sequence  $c_{long,1,n}$ .

Let  $n_{23}$  ...  $n_0$  be the 24 bit binary representation of the scrambling sequence number n with  $n_0$  being the least significant bit. The x sequence depends on the chosen scrambling sequence number n and is denoted  $x_n$ , in the sequel. Furthermore, let  $x_n(i)$  and y(i) denote the i:th symbol of the sequence  $x_n$  and y, respectively.

The *m*-sequences  $x_n$  and y are constructed as:

Initial conditions:

- $x_n(0)=n_0$ ,  $x_n(1)=n_1$ , ... = $x_n(22)=n_{22}$ ,  $x_n(23)=n_{23}$ ,  $x_n(24)=1$ .
- y(0)=y(1)=...=y(23)=y(24)=1.

Recursive definition of subsequent symbols:

- $x_n(i+25) = x_n(i+3) + x_n(i)$  modulo 2,  $i=0,..., 2^{25}-27$ .
- y(i+25) = y(i+3)+y(i+2)+y(i+1)+y(i) modulo 2,  $i=0,..., 2^{25}-27$ .

Define the binary Gold sequence  $z_n$  by:

-  $z_n(i) = x_n(i) + y(i)$  modulo 2,  $i = 0, 1, 2, ..., 2^{25}$ -2.

The real valued Gold sequence  $Z_n$  is defined by:

$$Z_n(i) = \begin{cases} +1 & \text{if } z_n(i) = 0\\ -1 & \text{if } z_n(i) = 1 \end{cases} \quad \text{for } i = 0, 1, \dots, 2^{25} - 2.$$

Now, the real-valued long scrambling sequences  $c_{long,1,n}$  and  $c_{long,2,n}$  are defined as follows:

$$c_{\text{long},1,n}(i) = Z_n(i), \ i = 0, 1, 2, ..., 2^{25} - 2 \text{ and}$$
 
$$c_{\text{long},2,n}(i) = Z_n((i+16777232) \text{ modulo } (2^{25}-1)), \ i = 0, 1, 2, ..., 2^{25}-2.$$

Finally, the complex-valued long scrambling sequence C<sub>long, n</sub>, is defined as:

$$C_{long,n}(i) = c_{long,1,n}(i) (1 + j(-1)^{i} c_{long,2,n} (2[i/2]))$$

where  $i = 0, 1, ..., 2^{25} - 2$  and  $\lfloor \rfloor$  denotes rounding to nearest lower integer.

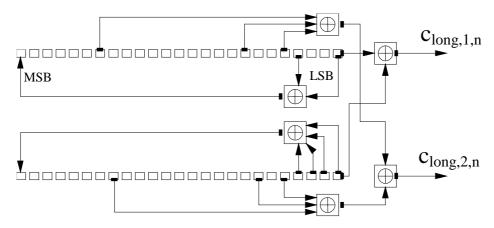

Figure 5: Configuration of uplink scrambling sequence generator

#### 4.3.2.3 Short scrambling sequence

The short scrambling sequences  $c_{\text{short},1,n}(i)$  and  $c_{\text{short},2,n}(i)$  are defined from a sequence from the family of periodically extended S(2) codes.

Let  $n_{23}n_{22}...n_0$  be the 24 bit binary representation of the code number n.

The n:th quaternary S(2) sequence  $z_n(i)$ ,  $0 \le n \le 16777215$ , is obtained by modulo 4 addition of three sequences, a quaternary sequence a(i) and two binary sequences b(i) and d(i), where the initial loading of the three sequences is determined from the code number n. The sequence  $z_n(i)$  of length 255 is generated according to the following relation:

$$z_n(i) = a(i) + 2b(i) + 2d(i) \text{ modulo } 4, i = 0, 1, ..., 254;$$

where the quaternary sequence a(i) is generated recursively by the polynomial  $g_0(x) = x^8 + 3x^5 + x^3 + 3x^2 + 2x + 3$  as:

- $a(0) = 2n_0 + 1 \mod 4$ ;
- $a(i) = 2n_i \text{ modulo } 4, i = 1, 2, ..., 7;$
- a(i) = 3a(i-3) + a(i-5) + 3a(i-6) + 2a(i-7) + 3a(i-8) modulo 4, i = 8, 9, ..., 254;

and the binary sequence b(i) is generated recursively by the polynomial  $g_1(x) = x^8 + x^7 + x^5 + x + 1$  as

$$b(i) = n_{8+i} \text{ modulo } 2, i = 0, 1, ..., 7,$$

$$b(i) = b(i-1) + b(i-3) + b(i-7) + b(i-8) \text{ modulo } 2, i = 8, 9, ..., 254,$$

and the binary sequence d(i) is generated recursively by the polynomial  $g_2(x) = x^8 + x^7 + x^5 + x^4 + 1$  as:

$$d(i) = n_{16+i} \text{ modulo } 2, i = 0, 1, ..., 7;$$

$$d(i) = d(i-1) + d(i-3) + d(i-4) + d(i-8)$$
 modulo 2,  $i = 8, 9, ..., 254$ .

The sequence  $z_n(i)$  is extended to length 256 chips by setting  $z_n(255) = z_n(0)$ .

The mapping from  $z_n(i)$  to the real-valued binary sequences  $c_{\text{short},1,n}(i)$  and  $c_{\text{short},2,n}(i)$ , , i = 0, 1, ..., 255 is defined in Table 2.

Table 2: Mapping from  $z_n(i)$  to  $c_{short,1,n}(i)$  and  $c_{short,2,n}(i)$ , i = 0, 1, ..., 255

$Z_n(i)$	C <sub>short,1,n</sub> (i)	C <sub>short,2,n</sub> (i)
0	+1	+1
1	-1	+1
2	-1	-1
3	+1	-1

Finally, the complex-valued short scrambling sequence C<sub>short, n</sub>, is defined as:

$$C_{short,n}(i) = c_{short,1,n}(i \mod 256) (1 + j(-1)^i c_{short,2,n}(2 \lfloor (i \mod 256) / 2 \rfloor))$$

where  $i = 0, 1, 2, \dots$  and  $\lfloor \rfloor$  denotes rounding to nearest lower integer.

An implementation of the short scrambling sequence generator for the 255 chip sequence to be extended by one chip is shown in Figure 6.

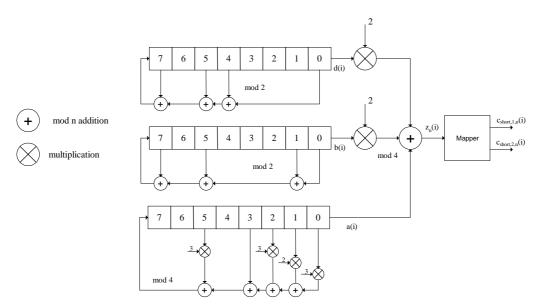

Figure 6: Uplink short scrambling sequence generator for 255 chip sequence

#### 4.3.2.4 Dedicated physical channels scrambling code

The code used for scrambling of the uplink dedicated physical channels may be of either long or short type. The n:th uplink scrambling code, denoted  $S_{dpch, n}$ , is defined as:

$$S_{dpch,n}(i) = C_{long,n}(i), i = 0, 1, ..., 38399$$
, when using long scrambling codes;

where the lowest index corresponds to the chip transmitted first in time and C<sub>long,n</sub> is defined in subclause 4.3.2.2.

The n:th uplink scrambling code, denoted  $S_{dpch, n}$ , is defined as:

$$S_{dpch,n}(i) = C_{short,n}(i), i = 0, 1, ..., 38399$$
, when using short scrambling codes;

where the lowest index corresponds to the chip transmitted first in time and  $C_{short,n}$  is defined in subclause 4.3.2.3.

#### 4.3.2.5 PRACH message part scrambling code

The scrambling code used for the PRACH message part is 10 ms long, and there are 8192 different PRACH scrambling codes defined.

The n:th PRACH message part scrambling code, denoted  $S_{r-msg,n}$ , where n = 0, 1, ..., 8191, is based on the long scrambling sequence and is defined as:

$$S_{r-msg,n}(i) = C_{long,n}(i + 4096), i = 0, 1, ..., 38399$$

where the lowest index corresponds to the chip transmitted first in time and C<sub>long,n</sub> is defined in subclause 4.3.2.2.

The message part scrambling code has a one-to-one correspondence to the scrambling code used for the preamble part. For one PRACH, the same code number is used for both scrambling codes, i.e. if the PRACH preamble scrambling code used is  $S_{r-pre,m}$  then the PRACH message part scrambling code is  $S_{r-msg,m}$ , where the number m is the same for both codes.

- 4.3.2.6 Void
- 4.3.2.7 Void

#### 4.3.3 PRACH preamble codes

#### 4.3.3.1 Preamble code construction

The random access preamble code  $C_{pre,n}$ , is a complex valued sequence. It is built from a preamble scrambling code  $S_{r-pre,n}$  and a preamble signature  $C_{sig,s}$  as follows:

- 
$$C_{\text{pre,n,s}}(k) = S_{\text{r-pre,n}}(k) \times C_{\text{sig,s}}(k) \times e^{j(\frac{\pi}{4} + \frac{\pi}{2}k)}, k = 0, 1, 2, 3, ..., 4095;$$

where k=0 corresponds to the chip transmitted first in time and  $S_{r-pre,n}$  and  $C_{sig,s}$  are defined in 4.3.3.2 and 4.3.3.3 below respectively.

#### 4.3.3.2 Preamble scrambling code

The scrambling code for the PRACH preamble part is constructed from the long scrambling sequences. There are 8192 PRACH preamble scrambling codes in total.

The *n*:th preamble scrambling code, n = 0, 1, ..., 8191, is defined as:

$$S_{r-pre,n}(i) = c_{long,1,n}(i), i = 0, 1, ..., 4095;$$

where the sequence  $c_{long,1,n}$  is defined in subclause 4.3.2.2.

The 8192 PRACH preamble scrambling codes are divided into 512 groups with 16 codes in each group. There is a one-to-one correspondence between the group of PRACH preamble scrambling codes in a cell and the primary scrambling code used in the downlink of the cell. The k:th PRACH preamble scrambling code within the cell with downlink primary scrambling code m, k = 0, 1, 2, ..., 15 and m = 0, 1, 2, ..., 511, is  $S_{r-pre,n}(i)$  as defined above with  $n = 16 \times m + k$ .

#### 4.3.3.3 Preamble signature

The preamble signature corresponding to a signature s consists of 256 repetitions of a length 16 signature  $P_s(n)$ , n=0...15. This is defined as follows:

- 
$$C_{\text{sig},s}(i) = P_s(i \text{ modulo } 16), i = 0, 1, ..., 4095.$$

The signature  $P_s(n)$  is from the set of 16 Hadamard codes of length 16. These are listed in table 3.

Preamble Value of n signature 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15  $P_0(n)$ 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1  $P_1(n)$ 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1  $P_2(n)$ -1 1 1 1 -1 -1 1 1 -1 -1 1 1 -1 1 -1 -1  $P_3(n)$ 1 1 -1 1 -1 1 -1 -1 1 -1 -1 1 1 -1 1 -1  $P_4(n)$ 1 1 1 1 -1 -1 -1 -1 1 1 1 1 -1 -1 -1 -1  $P_5(n)$ 1 -1 1 -1 -1 1 -1 1 1 -1 1 -1 -1 1 -1 1  $P_6(n)$ 1 1 -1 -1 -1 -1 1 1 1 1 -1 -1 -1 -1 1 1  $P_7(n)$ 1 -1 -1 1 -1 1 -1 1 -1 1 -1 1 1 -1 1 -1 P<sub>8</sub>(n) 1 1 1 1 1 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1 P<sub>9</sub>(n) 1 -1 1 -1 1 -1 1 -1 -1 1 -1 1 -1 1 -1 1 1 -1 1 -1 -1 1 -1 -1 1  $P_{10}(n)$ 1 -1 1 -1 -1 1 1 P<sub>11</sub>(n) 1 -1 -1 1 1 -1 -1 1 -1 1 1 -1 -1 1 1 -1 -1 -1 -1 -1  $P_{12}(n)$ 1 1 1 1 -1 -1 -1 -1 1 1 1 1 P<sub>13</sub>(n) 1 -1 1 -1 -1 1 -1 1 -1 1 -1 1 1 -1 1 -1 P<sub>14</sub>(n) 1 1 -1 -1 -1 -1 1 1 -1 -1 1 1 1 1 -1 -1 -1 1 -1 -1 P<sub>15</sub>(n) -1 -1

**Table 3: Preamble signatures** 

#### 4.3.4 Void

#### 4.4 Modulation

#### 4.4.1 Modulating chip rate

The modulating chip rate is 3.84 Mcps.

#### 4.4.2 Modulation

Modulation of the complex-valued chip sequence generated by the spreading process is shown in Figure 7 below:

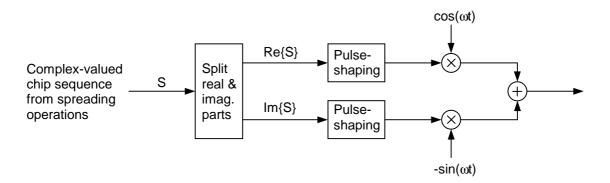

Figure 7: Uplink modulation

The pulse-shaping characteristics are described in [3].

## 5 Downlink spreading and modulation

## 5.1 Spreading

Figure 8 illustrates the spreading operation for all physical channel except SCH. The spreading operation includes a modulation mapper stage successively followed by a channelisation stage, an IQ combining stage and a scrambling stage. All the downlink physical channels are then combined as specified in sub subclause 5.1.5.

The non-spread downlink physical channels, except SCH, AICH, E-HICH and E-RGCH consist of a sequence of 3-valued digits taking the values 0, 1 and "DTX". Note that "DTX" is only applicable to those downlink physical channels that support DTX transmission.

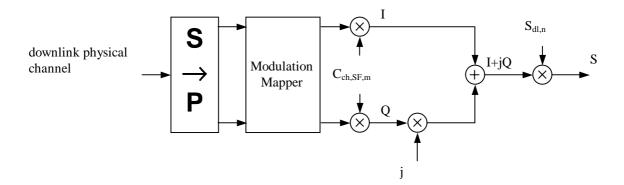

Figure 8: Spreading for all downlink physical channels except SCH

NOTE: Although subclause 5.1 has been reorganized in this release, the spreading operation as specified for the DL channels in the previous release remains unchanged.

### 5.1.1 Modulation mapper

Table 3A defines which of the IQ mapping specified in subclauses 5.1.1.1 and 5.1.1.2 may be used for the physical channel being processed.

Physical channelIQ mappingHS-PDSCHQPSK or 16QAMAll other channels<br/>(except the SCH)QPSK

Table 3A: IQ mapping

#### 5.1.1.1 QPSK

For all channels, except AICH, E-HICH and E-RGCH, the input digits shall be mapped to real-valued symbols as follows: the binary value "0" is mapped to the real value +1, the binary value "1" is mapped to the real value -1 and "DTX" is mapped to the real value 0.

For the indicator channels using signatures (AICH), the real-valued input symbols depend on the exact combination of the indicators to be transmitted as specified in [2] subclauses 5.3.3.7, 5.3.3.8 and 5.3.3.9. For the E-HICH and the E-RGCH the input is a real valued symbol sequence as specified in [2]

Each pair of two consecutive real-valued symbols is first converted from serial to parallel and mapped to an I and Q branch. The definition of the modulation mapper is such that even and odd numbered symbols are mapped to the I and Q branch respectively. For all QPSK channels except the indicator channels using signatures, symbol number zero is defined as the first symbol in each frame or sub-frame. For the indicator channels using signatures, symbol number zero is defined as the first symbol in each access slot.

#### 5.1.1.2 16QAM

In case of 16QAM, a set of four consecutive binary symbols  $n_k$ ,  $n_{k+1}$ ,  $n_{k+2}$ ,  $n_{k+3}$  (with  $k \mod 4 = 0$ ) is serial-to-parallel converted to two consecutive binary symbols ( $i_I = n_k$ ,  $i_2 = n_{k+2}$ ) on the I branch and two consecutive binary symbols ( $q_I = n_{k+1}$ ,  $q_2 = n_{k+3}$ ) on the Q branch and then mapped to 16QAM by the modulation mapper as defined in table 3B.

The I and Q branches are then both spread to the chip rate by the same real-valued channelisation code  $C_{ch,16,m}$ . The channelisation code sequence shall be aligned in time with the symbol boundary. The sequences of real-valued chips on the I and Q branch are then treated as a single complex-valued sequence of chips. This sequence of chips from all multicodes is summed and then scrambled (complex chip-wise multiplication) by a complex-valued scrambling code  $S_{dl,n}$ . The scrambling code is applied aligned with the scrambling code applied to the P-CCPCH.

$i_1q_1i_2q_2$	I branch	Q branch
0000	0.4472	0.4472
0001	0.4472	1.3416
0010	1.3416	0.4472
0011	1.3416	1.3416
0100	0.4472	-0.4472
0101	0.4472	-1.3416
0110	1.3416	-0.4472
0111	1.3416	-1.3416
1000	-0.4472	0.4472
1001	-0.4472	1.3416
1010	-1.3416	0.4472
1011	-1.3416	1.3416
1100	-0.4472	-0.4472
1101	-0.4472	-1.3416
1110	-1.3416	-0.4472
1111	-1.3416	-1.3416

Table 3B: 16 QAM modulation mapping

#### 5.1.2 Channelisation

For all physical channels (except SCH) the I and Q branches shall be spread to the chip rate by the same real-valued channelisation code  $C_{\text{ch,SF,m}}$ , i.e. the output for each input symbol on the I and the Q branches shall be a sequence of SF chips corresponding to the channelisation code chip sequence multiplied by the real-valued symbol. The channelisation code sequence shall be aligned in time with the symbol boundary.

#### 5.1.3 IQ combining

The real valued chip sequence on the Q branch shall be complex multiplied with j and summed with the corresponding real valued chip sequence on the I branch, thus resulting in a single complex valued chip sequence.

## 5.1.4 Scrambling

The sequence of complex valued chips shall be scrambled (complex chip-wise multiplication) by a complex-valued scrambling code  $S_{dl,n}$ . In case of P-CCPCH, the scrambling code shall be applied aligned with the P-CCPCH frame boundary, i.e. the first complex chip of the spread P-CCPCH frame is multiplied with chip number zero of the scrambling code. In case of other downlink channels, the scrambling code shall be applied aligned with the scrambling code applied to the P-CCPCH. In this case, the scrambling code is thus not necessarily applied aligned with the frame boundary of the physical channel to be scrambled.

## 5.1.5 Channel combining

Figure 9 illustrates how different downlink channels are combined. Each complex-valued spread channel, corresponding to point S in Figure 8, may be separately weighted by a weight factor  $G_i$ . The complex-valued P-SCH and S-SCH, as described in [2], subclause 5.3.3.5, may be separately weighted by weight factors  $G_p$  and  $G_s$ . All downlink physical channels shall then be combined using complex addition.

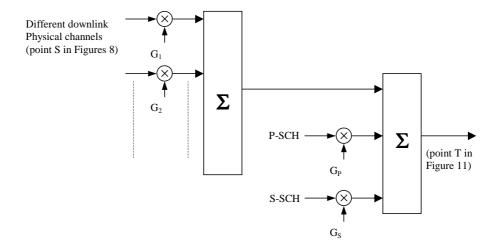

Figure 9: Combining of downlink physical channels

## 5.2 Code generation and allocation

#### 5.2.1 Channelisation codes

The channelisation codes of figure 8 are the same codes as used in the uplink, namely Orthogonal Variable Spreading Factor (OVSF) codes that preserve the orthogonality between downlink channels of different rates and spreading factors. The OVSF codes are defined in figure 4 in subclause 4.3.1.

The channelisation code for the Primary CPICH is fixed to  $C_{ch,256,0}$  and the channelisation code for the Primary CCPCH is fixed to  $C_{ch,256,1}$ . The channelisation codes for all other physical channels are assigned by UTRAN.

With the spreading factor 512 a specific restriction is applied. When the code word  $C_{ch,512,n}$ , with n=0,2,4....510, is used in soft handover, then the code word  $C_{ch,512,n+1}$  is not allocated in the cells where timing adjustment is to be used. Respectively if  $C_{ch,512,n}$ , with n=1,3,5....511 is used, then the code word  $C_{ch,512,n-1}$  is not allocated in the cells where timing adjustment is to be used. This restriction shall not apply in cases where timing adjustments in soft handover are not used with spreading factor 512.

When compressed mode is implemented by reducing the spreading factor by 2, the OVSF code used for compressed frames is:

- $C_{ch,SF/2,\lfloor n/2\rfloor}$  if ordinary scrambling code is used.
- $C_{ch,SF/2,n \text{ mod }SF/2}$  if alternative scrambling code is used (see subclause 5.2.2);

where C<sub>ch,SF,n</sub> is the channelisation code used for non-compressed frames.

For F-DPCH, the spreading factor is always 256.

For HS-PDSCH, the spreading factor is always 16.

For HS-SCCH, the spreading factor is always 128.

Channelisation-code-set information over HS-SCCH is mapped in following manner: the OVSF codes shall be allocated in such a way that they are positioned in sequence in the code tree. That is, for P multicodes at offset O the following codes are allocated:

$$C_{ch,16,O} \dots C_{ch,16,O+P-1}$$

The number of multicodes and the corresponding offset for HS-PDSCHs mapped from a given HS-DSCH is signalled by HS-SCCH.

For E-HICH and for E-RGCH, the spreading factor shall always be 128. In each cell, the E-RGCH and E-HICH assigned to a UE shall be configured with the same channelisation code.

For E-AGCH, the spreading factor shall always be 256.

#### 5.2.2 Scrambling code

A total of  $2^{18}$ -1 = 262,143 scrambling codes, numbered 0...262,142 can be generated. However not all the scrambling codes are used. The scrambling codes are divided into 512 sets each of a primary scrambling code and 15 secondary scrambling codes.

The primary scrambling codes consist of scrambling codes n=16\*i where i=0...511. The i:th set of secondary scrambling codes consists of scrambling codes 16\*i+k, where k=1...15.

There is a one-to-one mapping between each primary scrambling code and 15 secondary scrambling codes in a set such that i:th primary scrambling code corresponds to i:th set of secondary scrambling codes.

Hence, according to the above, scrambling codes k=0,1,...,8191 are used. Each of these codes are associated with a left alternative scrambling code and a right alternative scrambling code, that may be used for compressed frames. The left alternative scrambling code corresponding to scrambling code k is scrambling code number k+8192, while the right alternative scrambling code corresponding to scrambling code k is scrambling code number k+16384. The alternative scrambling codes can be used for compressed frames. In this case, the left alternative scrambling code is used if n < SF/2 and the right alternative scrambling code is used if n < SF/2, where  $c_{ch,SF,n}$  is the channelisation code used for non-compressed frames. The usage of alternative scrambling code for compressed frames is signalled by higher layers for each physical channel respectively.

In case F-DPCH is configured in the downlink, the same scrambling code and OVSF code shall be used in F-DPCH compressed frames and normal frames.

The set of primary scrambling codes is further divided into 64 scrambling code groups, each consisting of 8 primary scrambling codes. The j:th scrambling code group consists of primary scrambling codes 16\*8\*j+16\*k, where j=0..63 and k=0..7.

Each cell is allocated one and only one primary scrambling code. The primary CCPCH, primary CPICH, PICH, MICH, AICH and S-CCPCH carrying PCH shall always be transmitted using the primary scrambling code. The other downlink physical channels may be transmitted with either the primary scrambling code or a secondary scrambling code from the set associated with the primary scrambling code of the cell.

The mixture of primary scrambling code and no more than one secondary scrambling code for one CCTrCH is allowable. In compressed mode during compressed frames, these can be changed to the associated left or right scrambling codes as described above, i.e. in these frames, the total number of different scrambling codes may exceed two

In the case of CCTrCH of type of HS-DSCH then all the HS-PDSCH channelisation codes and HS-SCCH that a single UE may receive shall be under a single scrambling code (either the primary or a secondary scrambling code).

In each cell, the F-DPCH, E-RGCH, E-HICH and E-AGCH assigned to a UE shall be configured with same scrambling code as the assigned phase reference (primary or secondary CPICH).

In each cell the UE may be configured simultaneously with at most two scrambling codes.

The scrambling code sequences are constructed by combining two real sequences into a complex sequence. Each of the two real sequences are constructed as the position wise modulo 2 sum of 38400 chip segments of two binary m-sequences generated by means of two generator polynomials of degree 18. The resulting sequences thus constitute segments of a set of Gold sequences. The scrambling codes are repeated for every 10 ms radio frame. Let x and y be the two sequences respectively. The x sequence is constructed using the primitive (over GF(2)) polynomial  $1+X^7+X^{18}$ . The y sequence is constructed using the polynomial  $1+X^5+X^{7}+X^{10}+X^{18}$ .

The sequence depending on the chosen scrambling code number n is denoted  $z_n$ , in the sequel. Furthermore, let x(i), y(i) and  $z_n(i)$  denote the i:th symbol of the sequence x, y, and  $z_n$ , respectively.

The *m*-sequences *x* and *y* are constructed as:

Initial conditions:

- x is constructed with x(0)=1, x(1)=x(2)=...=x(16)=x(17)=0.
- y(0)=y(1)=...=y(16)=y(17)=1.

Recursive definition of subsequent symbols:

- $x(i+18) = x(i+7) + x(i) \text{ modulo } 2, i=0,...,2^{18}-20.$
- y(i+18) = y(i+10)+y(i+7)+y(i+5)+y(i) modulo 2,  $i=0,..., 2^{18}-20$ .

The n:th Gold code sequence  $z_n$ ,  $n=0,1,2,...,2^{18}-2$ , is then defined as:

-  $z_n(i) = x((i+n) \text{ modulo } (2^{18} - 1)) + y(i) \text{ modulo } 2, i=0,..., 2^{18}-2.$ 

These binary sequences are converted to real valued sequences Z<sub>n</sub> by the following transformation:

$$Z_n(i) = \begin{cases} +1 & \text{if } z_n(i) = 0 \\ -1 & \text{if } z_n(i) = 1 \end{cases} \quad \text{for} \quad i = 0, 1, \dots, 2^{18} - 2.$$

Finally, the n:th complex scrambling code sequence  $S_{dl,n}$  is defined as:

-  $S_{dl,n}(i) = Z_n(i) + j Z_n((i+131072) \text{ modulo } (2^{18}-1)), i=0,1,...,38399.$ 

Note that the pattern from phase 0 up to the phase of 38399 is repeated.

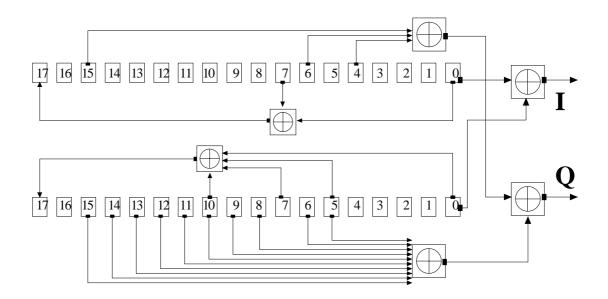

Figure 10: Configuration of downlink scrambling code generator

#### 5.2.3 Synchronisation codes

#### 5.2.3.1 Code generation

The primary synchronisation code (PSC),  $C_{psc}$  is constructed as a so-called generalised hierarchical Golay sequence. The PSC is furthermore chosen to have good aperiodic auto correlation properties.

Define:

$$-\quad a=<\!\!x_1,\,x_2,\,x_3,\,\ldots,\,x_{16}\!\!>\,=\,<\!\!1,\,1,\,1,\,1,\,1,\,1,\,-1,\,-1,\,1,\,-1,\,1,\,-1,\,1,\,-1,\,1,\,-1,\,1>$$

The PSC is generated by repeating the sequence a modulated by a Golay complementary sequence, and creating a complex-valued sequence with identical real and imaginary components. The PSC  $C_{psc}$  is defined as:

- 
$$C_{psc} = (1 + j) \times \langle a, a, a, -a, -a, a, -a, -a, a, a, -a, a, -a, a, -a, a, a \rangle$$
;

where the leftmost chip in the sequence corresponds to the chip transmitted first in time.

The 16 secondary synchronization codes (SSCs),  $\{C_{ssc,1},...,C_{ssc,16}\}$ , are complex-valued with identical real and imaginary components, and are constructed from position wise multiplication of a Hadamard sequence and a sequence z, defined as:

- $b = \langle x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, -x_9, -x_{10}, -x_{11}, -x_{12}, -x_{13}, -x_{14}, -x_{15}, -x_{16} \rangle$  and  $x_1, x_2, \dots, x_{15}, x_{16}$ , are same as in the definition of the sequence a above.

The Hadamard sequences are obtained as the rows in a matrix  $H_8$  constructed recursively by:

$$H_{0} = (1)$$

$$H_{k} = \begin{pmatrix} H_{k-1} & H_{k-1} \\ H_{k-1} & -H_{k-1} \end{pmatrix}, \quad k \ge 1$$

The rows are numbered from the top starting with row  $\theta$  (the all ones sequence).

Denote the n:th Hadamard sequence as a row of  $H_8$  numbered from the top, n = 0, 1, 2, ..., 255, in the sequel.

Furthermore, let  $h_n(i)$  and z(i) denote the i:th symbol of the sequence  $h_n$  and z, respectively where i = 0, 1, 2, ..., 255 and i = 0 corresponds to the leftmost symbol.

The k:th SSC,  $C_{ssc,k}$ , k = 1, 2, 3, ..., 16 is then defined as:

-  $C_{\text{ssc.k}} = (1+j) \times \langle h_m(0) \times z(0), h_m(1) \times z(1), h_m(2) \times z(2), \dots, h_m(255) \times z(255) \rangle$ ;

where  $m = 16 \times (k-1)$  and the leftmost chip in the sequence corresponds to the chip transmitted first in time.

#### 5.2.3.2 Code allocation of SSC

The 64 secondary SCH sequences are constructed such that their cyclic-shifts are unique, i.e., a non-zero cyclic shift less than 15 of any of the 64 sequences is not equivalent to some cyclic shift of any other of the 64 sequences. Also, a non-zero cyclic shift less than 15 of any of the sequences is not equivalent to itself with any other cyclic shift less than 15. Table 4 describes the sequences of SSCs used to encode the 64 different scrambling code groups. The entries in table 4 denote what SSC to use in the different slots for the different scrambling code groups, e.g. the entry "7" means that SSC C<sub>ssc 7</sub> shall be used for the corresponding scrambling code group and slot.

Table 4: Allocation of SSCs for secondary SCH

#### 5.3 Modulation

#### 5.3.1 Modulating chip rate

The modulating chip rate is 3.84 Mcps.

#### 5.3.2 Modulation

Modulation of the complex-valued chip sequence generated by the spreading process is shown in Figure 11 below.

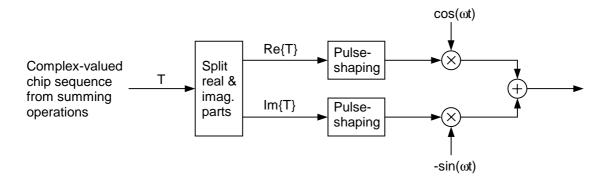

Figure 11: Downlink modulation

The pulse-shaping characteristics are described in [4].

## Annex A (informative): Generalised Hierarchical Golay Sequences

## A.1 Alternative generation

The generalised hierarchical Golay sequences for the PSC described in 5.2.3.1 may be also viewed as generated (in real valued representation) by the following methods:

#### Method 1.

The sequence y is constructed from two constituent sequences  $x_1$  and  $x_2$  of length  $n_1$  and  $n_2$  respectively using the following formula:

-  $y(i) = x_2(i \mod n_2) * x_1(i \operatorname{div} n_2), i = 0 ... (n_1 * n_2) - 1.$ 

The constituent sequences  $x_1$  and  $x_2$  are chosen to be the following length 16 (i.e.  $n_1 = n_2 = 16$ ) sequences:

- $x_1$  is defined to be the length 16 (N<sup>(1)</sup>=4) Golay complementary sequence obtained by the delay matrix D<sup>(1)</sup> = [8, 4, 1,2] and weight matrix W<sup>(1)</sup> = [1, -1, 1,1].
- x<sub>2</sub> is a generalised hierarchical sequence using the following formula, selecting s=2 and using the two Golay complementary sequences x<sub>3</sub> and x<sub>4</sub> as constituent sequences. The length of the sequence x<sub>3</sub> and x<sub>4</sub> is called n<sub>3</sub> respectively n<sub>4</sub>.
- $x_2(i) = x_4(i \mod s + s*(i \operatorname{div} sn_3)) * x_3((i \operatorname{div} s) \mod n_3), i = 0 \dots (n_3*n_4) 1.$
- $x_3$  and  $x_4$  are defined to be identical and the length 4 ( $N^{(3)} = N^{(4)} = 2$ ) Golay complementary sequence obtained by the delay matrix  $D^{(3)} = D^{(4)} = [1, 2]$  and weight matrix  $W^{(3)} = W^{(4)} = [1, 1]$ .

The Golay complementary sequences  $x_1, x_3$  and  $x_4$  are defined using the following recursive relation:

$$a_0(k) = \delta(k) \text{ and } b_0(k) = \delta(k);$$

$$a_n(k) = a_{n-1}(k) + W^{(j)}_{n} \cdot b_{n-1}(k - D^{(j)}_{n});$$

$$b_n(k) = a_{n-1}(k) - W^{(j)}_{n} \cdot b_{n-1}(k - D^{(j)}_{n});$$

$$k = 0, 1, 2, ..., 2^{**}N^{(j)} - 1;$$

$$n = 1, 2, ..., N^{(j)}.$$

The wanted Golay complementary sequence  $x_j$  is defined by  $a_n$  assuming  $n=N^{(j)}$ . The Kronecker delta function is described by  $\delta$ , k,j and n are integers.

#### Method 2

The sequence y can be viewed as a pruned Golay complementary sequence and generated using the following parameters which apply to the generator equations for a and b above:

(a) Let 
$$j = 0$$
,  $N^{(0)} = 8$ .

(b) 
$$[D_1^0, D_2^0, D_3^0, D_4^0, D_5^0, D_6^0, D_7^0, D_8^0] = [128, 64, 16, 32, 8, 1, 4, 2].$$

(c) 
$$[W_1^0, W_2^0, W_3^0, W_4^0, W_5^0, W_6^0, W_7^0, W_8^0] = [1, -1, 1, 1, 1, 1, 1, 1, 1]$$

(d) For 
$$n = 4$$
, 6, set  $b_4(k) = a_4(k)$ ,  $b_6(k) = a_6(k)$ .
